&-\frac{\cot(\theta)}{r^2\sin(\theta)}\cos(\theta)f_\phi-\frac{\cot(\theta)}{r^2\sin(\theta)}\sin(\theta)\partial_\theta f_\phi+\frac{1}{r^2\sin(\theta)}\partial_\theta\cos(\theta)f_\phi+\frac{1}{r^2\sin(\theta)}\partial_\theta\sin(\theta)\partial_\theta f_\phi\\
&=\frac{2}{r^2\sin(\theta)}\partial_\phi f_r+\frac{2\cot(\theta)}{r^2\sin(\theta)}\partial_\phi f_\theta+\frac{1}{r^2\sin^2(\theta)}\partial^2_\phi f_\phi+\frac{1}{r}\partial_r\partial_r f_\phi+\frac{1}{r}\partial_r r\partial_r f_\phi\\
&-\frac{\cot^2(\theta)}{r^2}f_\phi-\frac{\cot(\theta)}{r^2}\partial_\theta f_\phi+\frac{1}{r^2\sin(\theta)}\partial_\theta\cos(\theta)f_\phi+\frac{1}{r^2\sin(\theta)}\partial_\theta\sin(\theta)\partial_\theta f_\phi\\
&=\frac{2}{r^2\sin(\theta)}\partial_\phi f_r+\frac{2\cot(\theta)}{r^2\sin(\theta)}\partial_\phi f_\theta+\frac{1}{r^2\sin^2(\theta)}\partial^2_\phi f_\phi+\frac{1}{r}\partial_r\partial_r f_\phi+\frac{1}{r}\partial_r f_\phi+\partial^2_r f_\phi-\frac{\cot^2(\theta)}{r^2}f_\phi\\
&-\frac{\cot(\theta)}{r^2}\partial_\theta f_\phi-\frac{1}{r^2\sin(\theta)}\sin(\theta)f_\phi+\frac{1}{r^2\sin(\theta)}\cos(\theta)\partial_\theta f_\phi+\frac{1}{r^2\sin(\theta)}\cos(\theta)\partial_\theta f_\phi\\
&+\frac{1}{r^2\sin(\theta)}\sin(\theta)\partial^2_\theta f_\phi
\end{aligned}
\tag{6.5.430}
$$

$$\begin{aligned}
&=\frac{2}{r^2\sin(\theta)}\partial_\phi f_r+\frac{2\cot(\theta)}{r^2\sin(\theta)}\partial_\phi f_\theta+\frac{1}{r^2\sin^2(\theta)}\partial_\phi^2 f_\phi+\underbrace{\frac{2}{r}\partial_r f_\phi+\frac{1}{r}\partial_r^2 f_\phi}=\frac{1}{r}\partial_r^2 r f_\phi\\
&-\frac{\cot^2(\theta)}{r^2}f_\phi-\frac{\cot(\theta)}{r^2}\partial_\theta f_\phi-\frac{1}{r^2}f_\phi+\frac{\cot(\theta)}{r^2}\partial_\theta f_\phi+\frac{\cot(\theta)}{r^2}\partial_\theta f_\phi+\frac{1}{r^2}\partial_\theta^2 f_\phi\\
&=\frac{2}{r^2\sin(\theta)}\partial_\phi f_r+\frac{2\cot(\theta)}{r^2\sin(\theta)}\partial_\phi f_\theta+\frac{1}{r^2\sin^2(\theta)}\partial_\phi^2 f_\phi+\frac{1}{r}\partial_r^2 r f_\phi-\frac{1}{r^2}f_\phi(\cot^2(\theta)+1)\\
&+\frac{\cot(\theta)}{r^2}\partial_\theta f_\phi+\frac{1}{r^2}\partial_\theta^2 f_\phi
\end{aligned}\tag{6.5.431}$$

So what gives for the "vector Laplacian in spherical coordinates" as we can find it in tables or forms:

$$\boxed{\Delta\vec{f}=\begin{pmatrix}
-\dfrac{2f_r}{r^2}+\dfrac{\partial_r^2 r f_r}{r^2}-\dfrac{2\cot(\theta)f_\theta}{r^2}-\dfrac{2\partial_\theta f_\theta}{r^2}+\dfrac{\cot(\theta)\partial_\theta f_r}{r^2}+\dfrac{\partial_\theta^2 f_r}{r^2}+\dfrac{\partial_\phi^2 f_r}{r^2\sin^2(\theta)}-\dfrac{2\partial_\phi f_\phi}{r^2\sin^2(\theta)}\\
\dfrac{2\partial_\theta f_r}{r^2}-\dfrac{f_\theta}{r^2\sin^2(\theta)}+\dfrac{\cot(\theta)\partial_\theta f_\theta}{r^2}+\dfrac{\partial_\theta^2 f_\theta}{r^2}-\dfrac{2\cot(\theta)\partial_\phi f_\phi}{r^2\sin(\theta)}+\dfrac{\partial_\phi^2 f_\theta}{r^2\sin^2(\theta)}+\dfrac{\partial_r^2 r f_\theta}{r}\\
\dfrac{2\partial_\phi f_r}{r^2\sin(\theta)}+\dfrac{2\cot(\theta)\partial_\phi f_\theta}{r^2\sin(\theta)}+\dfrac{\partial_\phi^2 f_\phi}{r^2\sin^2(\theta)}+\dfrac{\partial_r^2 r f_\phi}{r}-\dfrac{f_\phi}{r^2\sin^2(\theta)}+\dfrac{\cot(\theta)\partial_\theta f_\phi}{r^2}+\dfrac{\partial_\theta^2 f_\phi}{r^2}
\end{pmatrix}}\tag{6.5.432}$$

that's it... for the sceptics...

6.5.8.7 Remarkable Identities

The scalar and vector differential operators have some very simple remarkable identities that we will find very often in physics in this textbook for practical purposes.

Let us first see the relations that make no sense (in case you would fall on them without purpose...):

$$\text{rot}(\text{div}(\vec{f}))\quad\text{or}\quad\vec{\nabla}\times(\vec{\nabla}\circ\vec{f})\tag{6.5.433}$$

For the relation above, the rotational (curl) of a divergence does not exist since the rotational operator applies to a vector field while the divergence is a scalar!

$$\text{rot}(\Delta\cdot f)\quad\text{or}\quad\vec{\nabla}\times(\Delta\cdot f)\tag{6.5.434}$$

For the above relation the rotational (curl) of a scalar Laplacian does not exist since the rotational operator applies to a vector field while by construction, the Laplacian is a scalar.

This done...! Let us now see some remarkable identities without proof for the majority (if there is a proof this is because one reader did the request to have all the details...):

1. By construction the scalar Laplacian is the divergence of the gradient of the scalar field:

$$\text{div}\left(\overrightarrow{\text{grad}}(f)\right)=\vec{\nabla}\circ\vec{\nabla}(f)=\vec{\nabla}^2 f=\Delta\cdot f\tag{6.5.435}$$

2. The rotational (curl) of the gradient is equal to zero:

$$\text{rot}\left(\overrightarrow{\text{grad}}(f)\right)=\vec{\nabla}\times(\vec{\nabla}f)=\vec{0} \tag{6.5.436}$$

Therefore if the rotational (curl) of a vector variable (vector field) is zero, this same variable can be expressed as the gradient of a scalar potential!!!!!!!!!!!! This is a veeeeerrrry important property (or trick depending of the point of view...) in Electromagnetics and Fluid Mechanics and Quantum Physics!

Proof 6.37.2.

$$\vec{\nabla}\times(\vec{\nabla}f)=\vec{\nabla}\times\begin{pmatrix}\dfrac{\partial f}{\partial x}\\\dfrac{\partial f}{\partial y}\\\dfrac{\partial f}{\partial z}\end{pmatrix}=\begin{pmatrix}\dfrac{\partial}{\partial y}\left(\dfrac{\partial f}{\partial z}\right)-\dfrac{\partial}{\partial z}\left(\dfrac{\partial f}{\partial y}\right)\\\dfrac{\partial}{\partial z}\left(\dfrac{\partial f}{\partial x}\right)-\dfrac{\partial}{\partial x}\left(\dfrac{\partial f}{\partial z}\right)\\\dfrac{\partial}{\partial x}\left(\dfrac{\partial f}{\partial y}\right)-\dfrac{\partial}{\partial y}\left(\dfrac{\partial f}{\partial x}\right)\end{pmatrix}=\vec{0} \tag{6.5.437}$$

■ Q.E.D.

3. The curl of a cross product, relation used sometimes in fluid mechanics (we will use it also!), is equal to:

$$\vec{\nabla}\times\left(\vec{f}\times\vec{g}\right)=\left(\vec{g}\circ\vec{\nabla}\right)\vec{f}-\vec{g}\left(\vec{\nabla}\circ\vec{f}\right)-\left(\vec{f}\circ\vec{\nabla}\right)\vec{g}+\vec{f}\left(\vec{\nabla}\circ\vec{g}\right) \tag{6.5.438}$$

Let us derive this:

Proof 6.37.3.

$$\begin{aligned}
\vec{\nabla}\times(\vec{f}\times\vec{g}) =& \nabla\times\left((f_yg_z-f_zg_y)\,\vec{i}+(f_zg_x-f_xg_z)\,\vec{j}+(f_xg_y-f_yg_x)\,\vec{k}\right)\\
=&\left(\frac{\partial}{\partial y}(f_xg_y-f_yg_x)-\frac{\partial}{\partial z}(f_zg_x-f_xg_z)\right)\vec{i}\\
&+\left(\frac{\partial}{\partial z}(f_yg_z-f_zg_y)-\frac{\partial}{\partial x}(f_xg_y-f_yg_x)\right)\vec{j}\\
&+\left(\frac{\partial}{\partial x}(f_zg_x-f_xg_z)-\frac{\partial}{\partial y}(f_yg_z-f_zg_y)\right)\vec{k}\\
=&\left(\frac{\partial f_xg_y}{\partial y}-\frac{\partial f_yg_x}{\partial y}-\frac{\partial f_zg_x}{\partial z}+\frac{\partial f_xg_z}{\partial z}\right)\vec{i}\\
&+\left(\frac{\partial f_yg_z}{\partial z}-\frac{\partial f_zg_y}{\partial z}-\frac{\partial f_xg_y}{\partial x}+\frac{\partial f_yg_x}{\partial x}\right)\vec{j}\\
&+\left(\frac{\partial f_zg_x}{\partial x}-\frac{\partial f_xg_z}{\partial x}-\frac{\partial f_yg_z}{\partial y}+\frac{\partial f_zg_y}{\partial y}\right)\vec{k}\\
=&\left(f_x\frac{\partial g_y}{\partial y}+\frac{\partial f_x}{\partial y}g_y-f_y\frac{\partial g_x}{\partial y}-\frac{\partial f_y}{\partial y}g_x-f_z\frac{\partial g_x}{\partial z}-\frac{\partial f_z}{\partial z}g_x+f_x\frac{\partial g_z}{\partial z}+\frac{\partial f_x}{\partial z}g_z\right)\vec{i}\\
&+\left(f_y\frac{\partial g_z}{\partial z}+\frac{\partial f_y}{\partial z}g_z-f_z\frac{\partial g_y}{\partial z}-\frac{\partial f_z}{\partial z}g_y-f_x\frac{\partial g_y}{\partial x}-\frac{\partial f_x}{\partial x}g_y+f_y\frac{\partial g_x}{\partial x}+\frac{\partial f_y}{\partial x}g_x\right)\vec{j}\\
&+\left(f_z\frac{\partial g_x}{\partial x}+\frac{\partial f_z}{\partial x}g_x-f_x\frac{\partial g_z}{\partial x}-\frac{\partial f_x}{\partial x}g_z-f_y\frac{\partial g_z}{\partial y}-\frac{\partial f_y}{\partial y}g_z+f_z\frac{\partial g_y}{\partial y}+\frac{\partial f_z}{\partial y}g_y\right)\vec{k}\\
=&\left(f_x\left(\frac{\partial g_y}{\partial y}+\frac{\partial g_z}{\partial z}\right)-\left(f_y\frac{\partial g_x}{\partial y}+f_z\frac{\partial g_x}{\partial z}\right)-\left(\frac{\partial f_y}{\partial y}+\frac{\partial f_z}{\partial z}\right)g_x+\left(\frac{\partial f_x}{\partial y}g_y+\frac{\partial f_x}{\partial z}g_z\right)\right)\vec{i}\\
&+\left(f_y\left(\frac{\partial g_x}{\partial x}+\frac{\partial g_z}{\partial z}\right)-\left(f_x\frac{\partial g_y}{\partial x}+f_z\frac{\partial g_y}{\partial z}\right)-\left(\frac{\partial f_x}{\partial x}+\frac{\partial f_z}{\partial z}\right)g_y+\left(\frac{\partial f_y}{\partial x}g_x+\frac{\partial f_y}{\partial z}g_z\right)\right)\vec{j}\\
&+\left(f_z\left(\frac{\partial g_x}{\partial x}+\frac{\partial g_y}{\partial y}\right)-\left(f_x\frac{\partial g_z}{\partial x}+f_y\frac{\partial g_z}{\partial y}\right)-\left(\frac{\partial f_x}{\partial x}+\frac{\partial f_y}{\partial y}\right)g_z+\left(\frac{\partial f_z}{\partial x}g_x+\frac{\partial f_z}{\partial y}g_y\right)\right)\vec{k}\\
=&\left(f_x\left(\frac{\partial g_x}{\partial x}+\frac{\partial g_y}{\partial y}+\frac{\partial g_z}{\partial z}\right)-\left(f_x\frac{\partial g_x}{\partial x}+f_y\frac{\partial g_x}{\partial y}+f_z\frac{\partial g_x}{\partial z}\right)-\left(\frac{\partial f_x}{\partial x}+\frac{\partial f_y}{\partial y}+\frac{\partial f_z}{\partial z}\right)g_x+\left(\frac{\partial f_x}{\partial x}g_x+\frac{\partial f_x}{\partial y}g_y+\frac{\partial f_x}{\partial z}g_z\right)\right)\vec{i}\\
&+\left(f_y\left(\frac{\partial g_x}{\partial x}+\frac{\partial g_y}{\partial y}+\frac{\partial g_z}{\partial z}\right)-\left(f_x\frac{\partial g_y}{\partial x}+f_y\frac{\partial g_y}{\partial y}+f_z\frac{\partial g_y}{\partial z}\right)-\left(\frac{\partial f_x}{\partial x}+\frac{\partial f_y}{\partial y}+\frac{\partial f_z}{\partial z}\right)g_y+\left(\frac{\partial f_y}{\partial x}g_x+\frac{\partial f_y}{\partial y}g_y+\frac{\partial f_y}{\partial z}g_z\right)\right)\vec{j}\\
&+\left(f_z\left(\frac{\partial g_x}{\partial x}+\frac{\partial g_y}{\partial y}+\frac{\partial g_z}{\partial z}\right)-\left(f_x\frac{\partial g_z}{\partial x}+f_y\frac{\partial g_z}{\partial y}+f_z\frac{\partial g_z}{\partial z}\right)-\left(\frac{\partial f_x}{\partial x}+\frac{\partial f_y}{\partial y}+\frac{\partial f_z}{\partial z}\right)g_z+\left(\frac{\partial f_z}{\partial x}g_x+\frac{\partial f_z}{\partial y}g_y+\frac{\partial f_z}{\partial z}g_z\right)\right)\vec{k}\\
=&\left(g_x\frac{\partial}{\partial x}+g_y\frac{\partial}{\partial y}+g_z\frac{\partial}{\partial z}\right)\left(f_x\vec{i}+f_y\vec{j}+f_z\vec{k}\right)-\left(g_x\vec{i}+g_y\vec{j}+g_z\vec{k}\right)\left(\frac{\partial f_x}{\partial x}+\frac{\partial f_y}{\partial y}+\frac{\partial f_z}{\partial z}\right)\\
&-\left(f_x\frac{\partial}{\partial x}+f_y\frac{\partial}{\partial y}+f_z\frac{\partial}{\partial z}\right)\left(g_x\vec{i}+g_y\vec{j}+g_z\vec{k}\right)+\left(f_x\vec{i}+f_y\vec{j}+f_z\vec{k}\right)\left(\frac{\partial g_x}{\partial x}+\frac{\partial g_y}{\partial y}+\frac{\partial g_z}{\partial z}\right)\\
=&\left(\vec{g}\circ\vec{\nabla}\right)\vec{f}-\vec{g}\left(\vec{\nabla}\circ\vec{f}\right)-\left(\vec{f}\circ\vec{\nabla}\right)\vec{g}+\vec{f}\left(\vec{\nabla}\circ\vec{g}\right)
\end{aligned}\tag{6.5.439}$$

■ Q.E.D.

4. The dot product of two rotational is equal to something boring to say just with words...:

$$(\vec{\nabla}\times\vec{x})\circ(\vec{\nabla}\times\vec{y})=\vec{y}\circ(\vec{\nabla}\times(\vec{\nabla}\times\vec{x}))+\vec{\nabla}\circ(\vec{y}\times(\vec{\nabla}\times\vec{x}))\tag{6.5.440}$$

5. The divergence of the rotational (curl) of a vector field is always equal to zero:

$$\text{div}\left(\text{rot}(\vec{f})\right)=0\quad\text{or}\quad\vec{\nabla}\circ(\vec{\nabla}\times\vec{f})=0\tag{6.5.441}$$

Proof 6.37.4.

$$\begin{aligned}
&\vec{\nabla}\circ(\vec{\nabla}\times\vec{f})=\vec{\nabla}\circ\left(\begin{pmatrix}\partial_x\\\partial_y\\\partial_z\end{pmatrix}\times\begin{pmatrix}f_1\\f_2\\f_3\end{pmatrix}\right)=\vec{\nabla}\circ\begin{pmatrix}\partial_yf_3-\partial_zf_2\\\partial_zf_1-\partial_xf_3\\\partial_xf_2-\partial_yf_1\end{pmatrix}\\
&=\begin{pmatrix}\partial_x\\\partial_y\\\partial_z\end{pmatrix}\circ\begin{pmatrix}\partial_yf_3-\partial_zf_2\\\partial_zf_1-\partial_xf_3\\\partial_xf_2-\partial_yf_1\end{pmatrix}=\partial_x(\partial_yf_3-\partial_zf_2)+\partial_y(\partial_zf_1-\partial_xf_3)+\partial_z(\partial_xf_2-\partial_yf_1)\\
&=\bcancel{\partial_x\partial_yf_3}-\cancel{\partial_x\partial_zf_2}+\xcancel{\partial_y\partial_z\partial_zf_1}-\bcancel{\partial_y\partial_xf_3}+\cancel{\partial_z\partial_xf_2}-\xcancel{\partial_z\partial_yf_1}=0
\end{aligned}\tag{6.5.442}$$

■ Q.E.D.

6. The rotational (curl) of the rotational of a vector field is equal to the gradient of the divergence of this vector field less its vector Laplacian:

$$\text{rot}(\text{rot}(\vec{f})) = \overrightarrow{\text{grad}}(\text{div}(\vec{f})) - \Delta\vec{f} \quad \text{or} \quad \vec{\nabla} \times (\vec{\nabla} \times \vec{f}) = \vec{\nabla}(\vec{\nabla} \circ \vec{f}) - \Delta\vec{f} \tag{6.5.443}$$

or also sometimes denoted:

$$\vec{\nabla} \times (\vec{\nabla} \times \vec{f}) = \vec{\nabla}(\vec{\nabla} \circ \vec{f}) - \nabla^2\vec{f} \tag{6.5.444}$$

That under the following rearrangement:

$$\nabla^2\vec{f} = \vec{\nabla} \times (\vec{\nabla} \times \vec{f}) - \vec{\nabla}(\vec{\nabla} \circ \vec{f}) \tag{6.5.445}$$

is named the "Hemholtz decomposition".

Proof 6.37.5.

$$\begin{aligned}\vec{\nabla} \times (\vec{\nabla} \times \vec{f}) &= \vec{\nabla} \times \left(\begin{pmatrix}\partial_x \\ \partial_y \\ \partial_z\end{pmatrix} \times \begin{pmatrix}f_1 \\ f_2 \\ f_3\end{pmatrix}\right) = \vec{\nabla} \times \begin{pmatrix}\partial_y f_3 - \partial_z f_2 \\ \partial_z f_1 - \partial_x f_3 \\ \partial_x f_2 - \partial_y f_1\end{pmatrix} = \begin{pmatrix}\partial_x \\ \partial_y \\ \partial_z\end{pmatrix} \times \begin{pmatrix}\partial_y f_3 - \partial_z f_2 \\ \partial_z f_1 - \partial_x f_3 \\ \partial_x f_2 - \partial_y f_1\end{pmatrix} \\ &= \begin{pmatrix}\partial_y(\partial_x f_2 - \partial_y f_1) - \partial_z(\partial_z f_1 - \partial_x f_3) \\ \partial_z(\partial_y f_3 - \partial_z f_2) - \partial_x(\partial_x f_2 - \partial_y f_1) \\ \partial_x(\partial_z f_1 - \partial_x f_3) - \partial_y(\partial_y f_3 - \partial_z f_2)\end{pmatrix}\end{aligned} \tag{6.5.446}$$

It is then easy to check that this last equality is equal to:

$$\begin{aligned}\vec{\nabla}(\vec{\nabla} \circ \vec{f}) - \Delta\vec{f} &= \vec{\nabla}\,(\partial_x f_1 + \partial_y f_2 + \partial_z f_3) - \Delta\vec{f} = \begin{pmatrix}\partial_x(\partial_x f_1 + \partial_y f_2 + \partial_z f_3) \\ \partial_y(\partial_x f_1 + \partial_y f_2 + \partial_z f_3) \\ \partial_z(\partial_x f_1 + \partial_y f_2 + \partial_z f_3)\end{pmatrix} - \Delta\vec{f} \\ &= \begin{pmatrix}\partial_x(\partial_x f_1 + \partial_y f_2 + \partial_z f_3) \\ \partial_y(\partial_x f_1 + \partial_y f_2 + \partial_z f_3) \\ \partial_z(\partial_x f_1 + \partial_y f_2 + \partial_z f_3)\end{pmatrix} - \begin{pmatrix}\dfrac{\partial^2 f_1}{\partial x^2} + \dfrac{\partial^2 f_1}{\partial y^2} + \dfrac{\partial^2 f_1}{\partial z^2} \\ \dfrac{\partial^2 f_2}{\partial x^2} + \dfrac{\partial^2 f_2}{\partial y^2} + \dfrac{\partial^2 f_2}{\partial z^2} \\ \dfrac{\partial^2 f_3}{\partial x^2} + \dfrac{\partial^2 f_3}{\partial y^2} + \dfrac{\partial^2 f_3}{\partial z^2}\end{pmatrix} \\ &= \begin{pmatrix}\partial_x(\partial_x f_1 + \partial_y f_2 + \partial_z f_3) - \dfrac{\partial^2 f_1}{\partial x^2} - \dfrac{\partial^2 f_1}{\partial y^2} - \dfrac{\partial^2 f_1}{\partial z^2} \\ \partial_y(\partial_x f_1 + \partial_y f_2 + \partial_z f_3) - \dfrac{\partial^2 f_2}{\partial x^2} - \dfrac{\partial^2 f_2}{\partial y^2} - \dfrac{\partial^2 f_2}{\partial z^2} \\ \partial_z(\partial_x f_1 + \partial_y f_2 + \partial_z f_3) - \dfrac{\partial^2 f_3}{\partial x^2} - \dfrac{\partial^2 f_3}{\partial y^2} - \dfrac{\partial^2 f_3}{\partial z^2}\end{pmatrix} \\ &= \begin{pmatrix}\partial_x(\partial_y f_2 + \partial_z f_3) - \dfrac{\partial^2 f_1}{\partial y^2} - \dfrac{\partial^2 f_1}{\partial z^2} \\ \partial_y(\partial_x f_1 + \partial_z f_3) - \dfrac{\partial^2 f_2}{\partial x^2} - \dfrac{\partial^2 f_2}{\partial z^2} \\ \partial_z(\partial_x f_1 + \partial_y f_2 +) - \dfrac{\partial^2 f_3}{\partial x^2} - \dfrac{\partial^2 f_3}{\partial y^2}\end{pmatrix} = \begin{pmatrix}\partial_y(\partial_x f_2 - \partial_y f_1) - \partial_y(\partial_z f_1 - \partial_x f_3) \\ \partial_z(\partial_y f_3 - \partial_z f_2) - \partial_x(\partial_x f_2 - \partial_y f_1) \\ \partial_x(\partial_z f_1 - \partial_x f_3) - \partial_y(\partial_y f_3 - \partial_z f_2)\end{pmatrix}\end{aligned} \tag{6.5.447}$$

■ Q.E.D.

7. The multiplication of the nabla operator by the dot product of two vectors is equal to ... (see below), which provides a very useful relation in Fluid Mechanics:

$$\vec{\nabla}\cdot(\vec{x}\circ\vec{y})=\vec{x}\times(\vec{\nabla}\times\vec{y})+\vec{y}\times(\vec{\nabla}\times\vec{x})+(\vec{y}\circ\vec{\nabla})\cdot\vec{x}+(\vec{x}\circ\vec{\nabla})\cdot\vec{y} \tag{6.5.448}$$

8. The scalar product of the rotational (curl) of a vector is the difference of the commutated operators such that (we can provide the detail proof on request):

$$\vec{x}\circ(\vec{\nabla}\times\vec{y})=\vec{y}\circ(\vec{\nabla}\times\vec{x})-\vec{\nabla}\circ(\vec{x}\times\vec{y}) \tag{6.5.449}$$

   We will use this last relation in our study of electromagnetic radiation pressure in the section of Electrodynamics (among others...).

9. The gradient of a cross product is the difference of the commutated operators such that (we can also provide the detail proof on request):

$$\vec{\nabla}(\vec{x}\times\vec{y})=\vec{y}\cdot(\text{rot}(\vec{x}))-\vec{x}\cdot(\text{rot}(\vec{y})) \tag{6.5.450}$$

   We will use this last relation in our study of superconductors in the section of Electrokinetics page 4307.

10. Let us consider a vector $\vec{v}$ which each component depends on x,y,z. We have (the left term is named the "material derivative", see section Continuum Mechanics page 3829):

$$(\vec{v}\circ\vec{\nabla})\vec{v}=\frac{1}{2}\vec{\nabla}\vec{v}^2-\vec{v}\times(\vec{\nabla}\times\vec{v}) \tag{6.5.451}$$

   Thus explicitly:

$$\left(\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}\circ\begin{pmatrix}\partial_x\\\partial_y\\\partial_z\end{pmatrix}\right)\cdot\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}=\frac{1}{2}\begin{pmatrix}\partial_x\\\partial_y\\\partial_z\end{pmatrix}\left\|\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}\right\|^2-\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}\times\left(\begin{pmatrix}\partial_x\\\partial_y\\\partial_z\end{pmatrix}\times\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}\right) \tag{6.5.452}$$

   Or even more explicit:

$$\left(\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}\circ\begin{pmatrix}\partial_x\\\partial_y\\\partial_z\end{pmatrix}\right)\cdot\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}=\frac{1}{2}\begin{pmatrix}\partial_x\\\partial_y\\\partial_z\end{pmatrix}(v_x^2+v_y^2+v_z^2)-\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}\times\left(\begin{pmatrix}\partial_x\\\partial_y\\\partial_z\end{pmatrix}\times\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}\right) \tag{6.5.453}$$

   So now to prove that the equality holds, we will develop the left part and right part. So let us begin with the left part:

$$\left(\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}\circ\begin{pmatrix}\partial_x\\\partial_y\\\partial_z\end{pmatrix}\right)\cdot\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix}=(v_x\partial_x+v_y\partial_y+v_z\partial_z)\begin{pmatrix}v_x\\v_y\\v_z\end{pmatrix} \tag{6.5.454}$$

Now let us develop the right part:

$$\begin{aligned}
&\frac{1}{2}\begin{pmatrix}\partial_x\\ \partial_y\\ \partial_z\end{pmatrix}(v_x^2+v_y^2+v_z^2)-\begin{pmatrix}v_x\\ v_y\\ v_z\end{pmatrix}\times\left(\begin{pmatrix}\partial_x\\ \partial_y\\ \partial_z\end{pmatrix}\times\begin{pmatrix}v_x\\ v_y\\ v_z\end{pmatrix}\right)\\
&=\begin{pmatrix}v_x\partial_x v_x+v_y\partial_x v_y+v_z\partial_x v_z\\ v_x\partial_y v_x+v_y\partial_y v_y+v_z\partial_y v_z\\ v_x\partial_z v_x+v_y\partial_z v_y+v_z\partial_z v_z\end{pmatrix}-\begin{pmatrix}v_x\\ v_y\\ v_z\end{pmatrix}\times\left(\begin{pmatrix}\partial_y v_z-\partial_z v_y\\ \partial_z v_x-\partial_x v_z\\ \partial_x v_y-\partial_y v_x\end{pmatrix}\right)\\
&=\begin{pmatrix}v_x\partial_x v_x+v_y\partial_x v_y+v_z\partial_x v_z\\ v_x\partial_y v_x+v_y\partial_y v_y+v_z\partial_y v_z\\ v_x\partial_z v_x+v_y\partial_z v_y+v_z\partial_z v_z\end{pmatrix}-\begin{pmatrix}v_y(\partial_x v_y-\partial_y v_x)-v_z(\partial_z v_x-\partial_x v_z)\\ v_z(\partial_y v_z-\partial_z v_y)-v_x(\partial_x v_y-\partial_y v_x)\\ v_x(\partial_z v_x-\partial_x v_z)-v_y(\partial_y v_z-\partial_z v_y)\end{pmatrix}\\
&=\begin{pmatrix}v_x\partial_x v_x+v_y\partial_x v_y+v_z\partial_x v_z-v_y\partial_x v_y+v_y\partial_y v_x+v_z\partial_z v_x-v_z\partial_x v_z\\ v_x\partial_y v_x+v_y\partial_y v_y+v_z\partial_y v_z-v_z\partial_y v_z+v_z\partial_z v_y+v_x\partial_x v_y-v_x\partial_y v_x\\ v_x\partial_z v_x+v_y\partial_z v_y+v_z\partial_z v_z-v_x\partial_z v_x+v_x\partial_x v_z+v_y\partial_y v_z-v_y\partial_z v_y\end{pmatrix}\\
&=\begin{pmatrix}v_x\partial_x v_x+v_y\partial_y v_x+v_z\partial_z v_x\\ v_y\partial_y v_y+v_z\partial_z v_y+v_x\partial_x v_y\\ v_z\partial_z v_z+v_x\partial_x v_z+v_y\partial_y v_z\end{pmatrix}
\end{aligned}\tag{6.5.455}$$

and then we see that the equality holds!

11. Now let us consider a chain rule sometimes useful in the upcoming sections (again about physics topics!). For this consider we start with:

$$\text{rot}\left(\frac{\vec{f}(x,y,z)}{g(x,y,z)}\right)=\begin{pmatrix}\dfrac{\partial(f_z/g)}{\partial y}-\dfrac{\partial(f_y/g)}{\partial z}\\ \dfrac{\partial(f_x/g)}{\partial z}-\dfrac{\partial(f_z/g)}{\partial x}\\ \dfrac{\partial(f_y/g)}{\partial x}-\dfrac{\partial(f_x/g)}{\partial y}\end{pmatrix}\tag{6.5.456}$$

Applying the quotient chain rule derived in the section of Differential and Integral Calculus:

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{f(x)}{g(x)}\right)=\frac{g(x)f'(x)-f(x)g'(x)}{[g(x)]^2}=\frac{g\partial_x f-f\partial_x g}{g^2}\tag{6.5.457}$$

we then get:

$$\begin{aligned}
\text{rot}\left(\frac{\vec{f}(x,y,z)}{g(x,y,z)}\right)&=\begin{pmatrix}\dfrac{\partial(f_z/g)}{\partial y}-\dfrac{\partial(f_y/g)}{\partial z}\\ \dfrac{\partial(f_x/g)}{\partial z}-\dfrac{\partial(f_z/g)}{\partial x}\\ \dfrac{\partial(f_y/g)}{\partial x}-\dfrac{\partial(f_x/g)}{\partial y}\end{pmatrix}=\frac{1}{g^2}\begin{pmatrix}(g\partial_y f_z-f_z\partial_y g)-(g\partial_z f_y-f_y\partial_z g)\\ (g\partial_z f_x-f_x\partial_z g)-(g\partial_x f_z-f_z\partial_x g)\\ (g\partial_x f_y-f_y\partial_x g)-(g\partial_y f_x-f_x\partial_y g)\end{pmatrix}\\
&=\frac{1}{g}\begin{pmatrix}\partial_y f_z-\partial_z f_y\\ \partial_z f_x-\partial_x f_z\\ \partial_x f_y-\partial_y f_x\end{pmatrix}+\frac{1}{g^2}\begin{pmatrix}-f_z\partial_y g+f_y\partial_z g\\ -f_x\partial_z g+f_z\partial_x g\\ -f_y\partial_x g+f_x\partial_y g\end{pmatrix}=\frac{1}{g}\vec{\nabla}\times\vec{f}-\frac{1}{g^2}\vec{\nabla}(g)\times\vec{f}\\
&=\frac{1}{g}\vec{\nabla}\times\vec{f}+\vec{\nabla}\left(\frac{1}{g}\right)\times\vec{f}
\end{aligned}\tag{6.5.458}$$

So finally:

$$\text{rot}\left(\frac{\vec{f}(x,y,z)}{g(x,y,z)}\right)=\frac{1}{g}\vec{\nabla}\times\vec{f}+\vec{\nabla}(\frac{1}{g})\times\vec{f} \tag{6.5.459}$$

or written:

$$\vec{\nabla}\times\left(\frac{\vec{f}(x,y,z)}{g(x,y,z)}\right)=\frac{1}{g}\vec{\nabla}\times\vec{f}+\vec{\nabla}(\frac{1}{g})\times\vec{f} \tag{6.5.460}$$

6.5.8.8 Summary

As part of this textbook, we will use the different notations presented and summarized in the table below. Their usage gives us the possibility in the context of the different theories to avoid confusion with other mathematics being (tools). It's annoying but we have to do with it.

Type	Expression
Gradient of a scalar field $A:\mathbb{R}\mapsto\mathbb{R}^3$	$\vec{\nabla}(f)\quad \vec{\nabla}\cdot f\quad \vec{\nabla}f\quad \overrightarrow{\text{grad}}(f)$
Gradient of a vector field $A:\mathbb{R}^n\mapsto\mathbb{R}^n\times\mathbb{R}^n$	$\vec{\nabla}(\vec{f})$
Divergence of a vector field $A:\mathbb{R}^n\mapsto\mathbb{R}$	$\vec{\nabla}\circ\vec{f}\quad \text{div}(\vec{f})$
Rotational of a vector field $A:\mathbb{R}^3\mapsto\mathbb{R}^3$	$\vec{\nabla}\times\vec{f}\quad \text{rot}(\vec{f})$
Laplacian of a scalar field $A:\mathbb{R}^n\mapsto\mathbb{R}$	$\Delta\cdot f\quad \vec{\nabla}^2 f\quad \vec{\nabla}\circ(\vec{\nabla}\cdot f)$
Laplacian of a vector field $A:\mathbb{R}^3\mapsto\mathbb{R}^3$	$\Delta\vec{f}$

Table 6.17: Summary of vector differential operators

Now let us do a quick summary of main differential operators:

- The gradient can be assimilated to the "slope" (example: the electric field is the "slope" of the electrostatic potential).

  The various expressions of the gradient operator (placed under the form of the nabla operator) in Cartesian, polar, cylindrical, spherical coordinates are the following:

$$\begin{aligned}
\vec{\nabla}&=\left(\frac{\partial}{\partial x},\frac{\partial}{\partial y},\frac{\partial}{\partial z}\right)\\
\vec{\nabla}&=\left(\frac{\partial}{\partial r},\frac{1}{r}\frac{\partial f}{\partial \phi}\right)\\
\vec{\nabla}&=\left(\frac{\partial}{\partial r},\frac{1}{r}\frac{\partial f}{\partial \phi},\frac{\partial}{\partial z}\right)\\
\vec{\nabla}&=\left(\frac{\partial}{\partial r},\frac{1}{r}\frac{\partial f}{\partial \phi},\frac{1}{r\sin\theta}\frac{\partial}{\partial \theta}\right)
\end{aligned}\tag{6.5.461}$$

- The divergence characterizes a flow of something that comes from somewhere, a source, or who goes to it. If the divergence is different from zero, it means that there is concentration around a point, so the density increases (or decreases, it depends on the sign). It could be the density of electric charges or the mass density. Hence the famous theorem that says that the flow (that which passes through a surface) is equal to the integral of the divergence (what remains).

  The various expressions of the divergence operator (placed under the form of the nabla operator) in Cartesian, polar, cylindrical, spherical coordinates are the following:

$$\begin{aligned}
\vec{\nabla} &= \left(\frac{\partial}{\partial x},\frac{\partial}{\partial y},\frac{\partial}{\partial z}\right)\\
\vec{\nabla} &= \left(\frac{1}{r}\frac{\partial(r}{\partial r},\frac{1}{r}\frac{\partial}{\partial\phi}\right)\\
\vec{\nabla} &= \left(\frac{1}{r}\frac{\partial(r}{\partial r},\frac{1}{r}\frac{\partial}{\partial\phi},\frac{\partial}{\partial z}\right)\\
\vec{\nabla} &= \left(\frac{1}{r^2}\frac{\partial(r^2}{\partial r},\frac{1}{r\sin(\theta)}\frac{\partial(\sin(\theta)}{\partial\theta},\frac{1}{r\sin(\theta)}\frac{\partial}{\partial\phi}\right)
\end{aligned}\tag{6.5.462}$$

- The rotational characterizes the existence of a vortex (widely used in fluid mechanics). If there is a whirlwind, we can follow a flow line on a closed curve (closed: in the differential point of view, not in the geometrical one!) without it change of direction: the circulation will the not be equal to zero (it is equal to integral of the rotational (curl)).

  The various expressions of the rotational (curl) operator (placed under the form of the nabla operator) in Cartesian, cylindrical, spherical coordinates are the following:

$$\begin{aligned}
\text{rot}(\vec{f}) = \vec{\nabla}\times\vec{f} &= \begin{pmatrix}\dfrac{\partial f_z}{\partial y}-\dfrac{\partial f_y}{\partial z}\\ \dfrac{\partial f_x}{\partial z}-\dfrac{\partial f_z}{\partial x}\\ \dfrac{\partial f_y}{\partial x}-\dfrac{\partial f_x}{\partial y}\end{pmatrix}\\
\text{rot}(\vec{f}) = \vec{\nabla}\times\vec{f} &= \begin{pmatrix}\dfrac{1}{r}\dfrac{\partial f_z}{\partial\phi}-\dfrac{\partial f_\phi}{\partial z}\\ \dfrac{\partial f_r}{\partial z}-\dfrac{\partial f_z}{\partial r}\\ \dfrac{1}{r}\dfrac{\partial(rf_\phi)}{\partial r}-\dfrac{1}{r}\dfrac{\partial f_r}{\partial\phi}\end{pmatrix}\\
\text{rot}(\vec{f}) = \vec{\nabla}\times\vec{f} &= \begin{pmatrix}\dfrac{1}{r\sin(\theta)}\dfrac{\partial}{\partial\theta}(\sin(\theta)f_\phi)-\dfrac{1}{r\sin(\theta)}\dfrac{\partial f_\theta}{\partial\phi}\\ \dfrac{1}{r\sin(\theta)}\dfrac{\partial f_r}{\partial\phi}-\dfrac{1}{r}\dfrac{\partial}{\partial r}(rf_\phi)\\ \dfrac{1}{r}\dfrac{\partial}{\partial r}(rf_\theta)-\dfrac{1}{r}\dfrac{\partial f_r}{\partial\theta}\end{pmatrix}
\end{aligned}\tag{6.5.463}$$

- The Laplacian of a scalar field gives a scalar field that measures the difference between the value of the function at a point and its average around that point. In other words, the partial second derivative measure the variations of the slope at the point examined in the immediate surroundings and in one dimension at a time. If the partial second derivative is zero in one direction, then the slope is constant in the immediate surroundings and according to this dimension, this means that the value of the function on the study is equal to the average of his neighbourhood (in one dimension).

  The different expressions of the scalar Laplacian operator (placed under the form of the nabla operator) in Cartesian, polar and spherical coordinates are:

$$\begin{aligned}\vec{\nabla}^2 &= \left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial y^2}\right)\\ \vec{\nabla}^2 &= \left(\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{1}{\partial r}+\frac{1}{r^2}\frac{\partial^2}{\partial \phi^2}\right)\\ \vec{\nabla}^2 &= \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{1}{r^2\sin(\theta)}\frac{\partial}{\partial\theta}\left(\sin(\theta)\frac{\partial\theta}{\partial\theta}\right)+\frac{1}{r^2\sin^2(\theta)}\frac{\partial^2}{\partial\phi^2}\end{aligned} \tag{6.5.464}$$

- As for the Laplacian of a scalar field, the Laplacian of a vector field is only a very convenient notation system for condensing the writing of the components of a vector field.

  The different expressions of the vectorial Laplacian operator (placed under the form of the nabla operator) in Cartesian, polar and spherical coordinates are:

$$\begin{aligned}\Delta\vec{f} &= \begin{pmatrix}\displaystyle\sum_{i=1}^{3}\frac{\partial^2 f_1}{\partial x_i^2}\\ \displaystyle\sum_{i=1}^{3}\frac{\partial^2 f_2}{\partial x_i^2}\\ \displaystyle\sum_{i=1}^{3}\frac{\partial^2 f_3}{\partial x_i^2}\end{pmatrix}\\ \Delta\vec{f} &= \begin{pmatrix}-\frac{1}{r^2}f_r+\frac{1}{r}\partial_r f_r+\partial_r^2 f_r-\frac{2}{r^2}\partial_\phi f_\phi+\frac{1}{r^2}\partial_\phi^2 f_r+\partial_z^2 f_r\\ \frac{2}{r^2}\partial_\phi f_r+\frac{1}{r^2}\partial_\phi^2 f_\phi+\partial_z^2 f_\phi+\partial_z^2 f_\phi-\frac{1}{r^2}f_\phi+\frac{1}{r}\partial_r f_\phi+\partial_r^2 f_\phi\\ \partial_z^2 f_z+\frac{1}{r}\partial_r f_z+\partial_r^2 f_z+\frac{1}{r^2}\partial_\phi^2 f_z\end{pmatrix}\\ \Delta\vec{f} &= \begin{pmatrix}-\frac{2f_r}{r^2}+\frac{\partial_r^2 r f_r}{r^2}-\frac{2\cot(\theta)f_\theta}{r^2}-\frac{2\partial_\theta f_\theta}{r^2}+\frac{\cot(\theta)\partial_\theta f_r}{r^2}+\frac{\partial_\theta^2 f_r}{r^2}+\frac{\partial_\phi^2 f_r}{r^2\sin^2(\theta)}-\frac{2\partial_\phi f_\phi}{r^2\sin^2(\theta)}\\ \frac{2\partial_\theta f_r}{r^2}-\frac{f_\theta}{r^2\sin^2(\theta)}+\frac{\cot(\theta)\partial_\theta f_\theta}{r^2}+\frac{\partial_\theta^2 f_\theta}{r^2}-\frac{2\cot(\theta)\partial_\phi f_\phi}{r^2\sin(\theta)}+\frac{\partial_\phi^2 f_\theta}{r^2\sin^2(\theta)}+\frac{\partial_r^2 r f_\theta}{r}\\ \frac{2\partial_\phi f_r}{r^2\sin(\theta)}+\frac{2\cot(\theta)\partial_\phi f_\theta}{r^2\sin(\theta)}+\frac{\partial_\phi^2 f_\phi}{r^2\sin^2(\theta)}+\frac{\partial_r^2 r f_\phi}{r}-\frac{f_\phi}{r^2\sin^2(\theta)}+\frac{\cot(\theta)\partial_\theta f_\phi}{r^2}+\frac{\partial_\theta^2 f_\phi}{r^2}\end{pmatrix}\end{aligned} \tag{6.5.465}$$

And also we have the following list of remarkable identities:

$$\text{rot}\left(\overrightarrow{\text{grad}}(f)\right)=\vec{\nabla}\times(\vec{\nabla}f)=\vec{0} \tag{6.5.466}$$

$$(\vec{\nabla}\times\vec{x})\circ(\vec{\nabla}\times\vec{y})=\vec{y}\circ(\vec{\nabla}\times(\vec{\nabla}\times\vec{x}))+\vec{\nabla}\circ(\vec{y}\times(\vec{\nabla}\times\vec{x})) \tag{6.5.467}$$

$$\text{div}\left(\text{rot}(\vec{f})\right)=0 \quad \text{or} \quad \vec{\nabla}\circ(\vec{\nabla}\times\vec{f})=0 \tag{6.5.468}$$

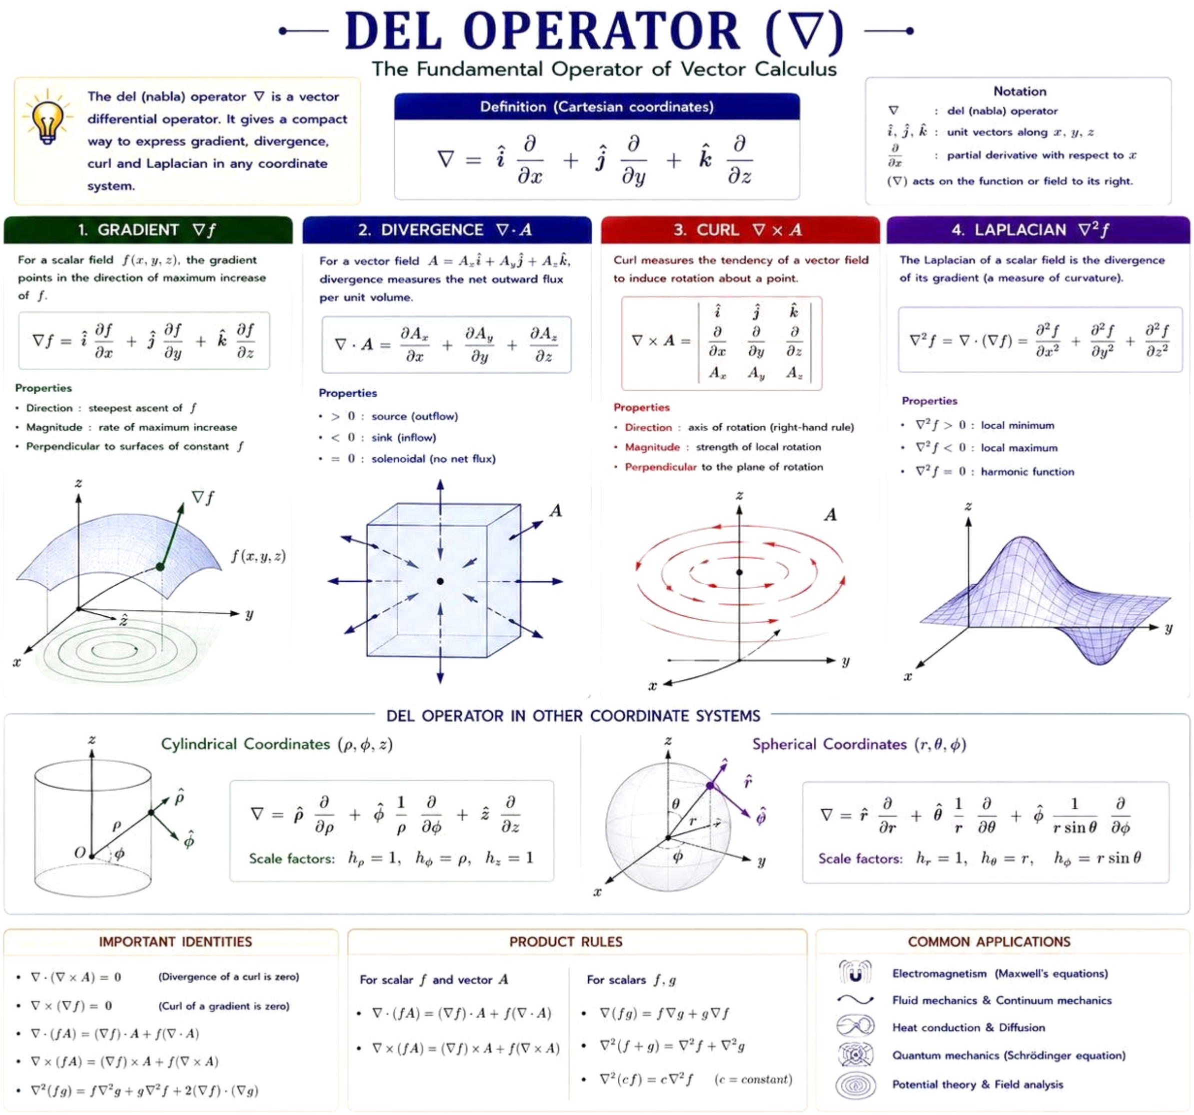
$$\text{rot}(\text{rot}(\vec{f}))=\overrightarrow{\text{grad}}(\text{div}(\vec{f}))-\Delta\vec{f} \quad \text{or} \quad \vec{\nabla}\times(\vec{\nabla}\times\vec{f})=\vec{\nabla}(\vec{\nabla}\circ\vec{f})-\Delta\vec{f} \tag{6.5.469}$$

$$\vec{\nabla}\cdot(\vec{x}\circ\vec{y})=\vec{x}\times(\vec{\nabla}\times\vec{y})+\vec{y}\times(\vec{\nabla}\times\vec{x})+(\vec{y}\circ\vec{\nabla})\cdot\vec{x}+(\vec{x}\circ\vec{\nabla})\cdot\vec{y} \tag{6.5.470}$$

$$\vec{x}\circ(\vec{\nabla}\times\vec{y})=\vec{y}\circ(\vec{\nabla}\times\vec{x})-\vec{\nabla}\circ(\vec{x}\times\vec{y}) \tag{6.5.471}$$

$$\vec{\nabla}(\vec{x}\times\vec{y})=\vec{y}\cdot(\text{rot}(\vec{x}))-\vec{x}\cdot(\text{rot}(\vec{y})) \tag{6.5.472}$$

$$(\vec{v}\circ\vec{\nabla})\vec{v}=\frac{1}{2}\vec{\nabla}\vec{v}^2-\vec{v}\times(\vec{\nabla}\times\vec{v}) \tag{6.5.473}$$



DEL OPERATOR (∇)

The Fundamental Operator of Vector Calculus

The del (nabla) operator ∇ is a vector differential operator. It gives a compact way to express gradient, divergence, curl and Laplacian in any coordinate system.

Definition (Cartesian coordinates)

$$\nabla = \hat{\imath}\,\frac{\partial}{\partial x} + \hat{\jmath}\,\frac{\partial}{\partial y} + \hat{k}\,\frac{\partial}{\partial z}$$

Notation

∇ : del (nabla) operator
$\hat{\imath},\hat{\jmath},\hat{k}$: unit vectors along x, y, z
$\frac{\partial}{\partial x}$: partial derivative with respect to x
(∇) acts on the function or field to its right.

1. GRADIENT ∇f

For a scalar field $f(x,y,z)$, the gradient points in the direction of maximum increase of f.

$$\nabla f = \hat{\imath}\,\frac{\partial f}{\partial x} + \hat{\jmath}\,\frac{\partial f}{\partial y} + \hat{k}\,\frac{\partial f}{\partial z}$$

Properties

- Direction : steepest ascent of f
- Magnitude : rate of maximum increase
- Perpendicular to surfaces of constant f

2. DIVERGENCE $\nabla\cdot A$

For a vector field $A = A_x\hat{\imath} + A_y\hat{\jmath} + A_z\hat{k}$, divergence measures the net outward flux per unit volume.

$$\nabla\cdot A = \frac{\partial A_x}{\partial x} + \frac{\partial A_y}{\partial y} + \frac{\partial A_z}{\partial z}$$

Properties

- > 0 : source (outflow)
- < 0 : sink (inflow)
- $= 0$: solenoidal (no net flux)

3. CURL $\nabla\times A$

Curl measures the tendency of a vector field to induce rotation about a point.

$$\nabla\times A = \begin{vmatrix} \hat{\imath} & \hat{\jmath} & \hat{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ A_x & A_y & A_z \end{vmatrix}$$

Properties

- **Direction** : axis of rotation (right-hand rule)
- **Magnitude** : strength of local rotation
- **Perpendicular** to the plane of rotation

4. LAPLACIAN $\nabla^2 f$

The Laplacian of a scalar field is the divergence of its gradient (a measure of curvature).

$$\nabla^2 f = \nabla\cdot(\nabla f) = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}$$

Properties

- $\nabla^2 f > 0$: local minimum
- $\nabla^2 f < 0$: local maximum
- $\nabla^2 f = 0$: harmonic function

DEL OPERATOR IN OTHER COORDINATE SYSTEMS

Cylindrical Coordinates (ρ, ϕ, z)

$$\nabla = \hat{\rho}\,\frac{\partial}{\partial \rho} + \hat{\phi}\,\frac{1}{\rho}\,\frac{\partial}{\partial \phi} + \hat{z}\,\frac{\partial}{\partial z}$$

Scale factors: $h_\rho = 1,\ h_\phi = \rho,\ h_z = 1$

Spherical Coordinates (r, θ, ϕ)

$$\nabla = \hat{r}\,\frac{\partial}{\partial r} + \hat{\theta}\,\frac{1}{r}\,\frac{\partial}{\partial \theta} + \hat{\phi}\,\frac{1}{r\sin\theta}\,\frac{\partial}{\partial \phi}$$

Scale factors: $h_r = 1,\ h_\theta = r,\ h_\phi = r\sin\theta$

IMPORTANT IDENTITIES

- $\nabla\cdot(\nabla\times A) = 0$ (Divergence of a curl is zero)
- $\nabla\times(\nabla f) = 0$ (Curl of a gradient is zero)
- $\nabla\cdot(fA) = (\nabla f)\cdot A + f(\nabla\cdot A)$
- $\nabla\times(fA) = (\nabla f)\times A + f(\nabla\times A)$
- $\nabla^2(fg) = f\nabla^2 g + g\nabla^2 f + 2(\nabla f)\cdot(\nabla g)$

PRODUCT RULES

For scalar f and vector A

- $\nabla\cdot(fA) = (\nabla f)\cdot A + f(\nabla\cdot A)$
- $\nabla\times(fA) = (\nabla f)\times A + f(\nabla\times A)$

For scalars f, g

- $\nabla(fg) = f\nabla g + g\nabla f$
- $\nabla^2(f+g) = \nabla^2 f + \nabla^2 g$
- $\nabla^2(cf) = c\nabla^2 f$ (c = constant)

COMMON APPLICATIONS

- Electromagnetism (Maxwell's equations)
- Fluid mechanics & Continuum mechanics
- Heat conduction & Diffusion
- Quantum mechanics (Schrödinger equation)
- Potential theory & Field analysis

Finally let us finish this summary with all the theorems that we have obtained so far in this section that are named "first order integral theorems":

- Gradient theorem (only for uniform field):

$$\iiint_V \vec{\nabla}(f)\mathrm{d}V = \oiint_S f\mathrm{d}\vec{S} \tag{6.5.474}$$

- Ostrogradsky theorem (divergence theorem):

$$\Phi = \iiint_V (\vec{\nabla}\circ\vec{f})\mathrm{d}V = \oiint_S \vec{f}\circ\mathrm{d}\vec{S} \tag{6.5.475}$$

- Green theorem (Green-Riemann theorem):

$$\oint_C (f_x\mathrm{d}x + f_y\mathrm{d}y) = \int_S \left(\frac{\partial f_y}{\partial x} - \frac{\partial f_x}{\partial y}\right)\mathrm{d}S_z \tag{6.5.476}$$

- Stokes theorem (curl theorem):

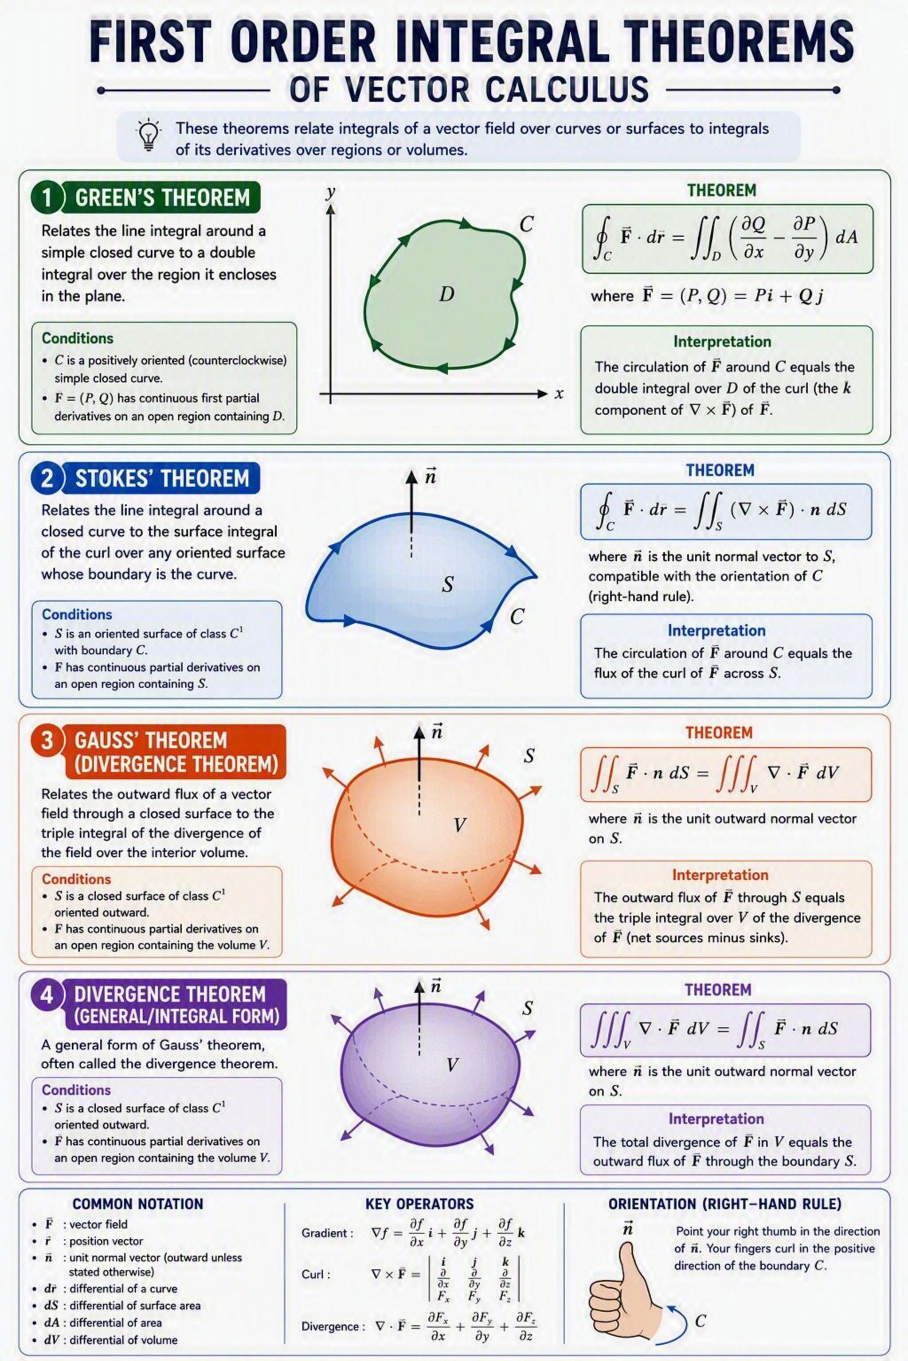
$$\oint \vec{f} \circ \mathrm{d}\vec{r} = \int\limits_S \left(\vec{\nabla} \times \vec{f}\right) \circ \mathrm{d}\vec{S} \qquad (6.5.477)$$

Keep in mind that they are all special case of the Stokes theorem (general manifold theorem[19]) including the fundamental theorem of calculus!

Then the fundamental theorem of calculus (1D), Green's theorem (2D) and the divergence theorem (3D) (i.e. Stokes original theorem) can all be stated respectively by the following parametrised sentence (still special case of Stokes general manifold theorem): *The total [change, spin, flow] outside is equal to the sum of little [changes, spins, flows] on the inside*.

---

[19] If one day we have the time to write the LaTeXto provide a detailed example we will! But actually that doesn't bring too much interest for an engineer.



FIRST ORDER INTEGRAL THEOREMS
OF VECTOR CALCULUS

These theorems relate integrals of a vector field over curves or surfaces to integrals of its derivatives over regions or volumes.

1 GREEN'S THEOREM

Relates the line integral around a simple closed curve to a double integral over the region it encloses in the plane.

Conditions
- C is a positively oriented (counterclockwise) simple closed curve.
- $\mathbf{F} = (P, Q)$ has continuous first partial derivatives on an open region containing D.

THEOREM

$$\oint_C \vec{\mathbf{F}} \cdot d\vec{r} = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA$$

where $\vec{\mathbf{F}} = (P, Q) = P\boldsymbol{i} + Q\,\boldsymbol{j}$

Interpretation

The circulation of $\vec{\mathbf{F}}$ around C equals the double integral over D of the curl (the $\boldsymbol{k}$ component of $\nabla \times \vec{\mathbf{F}}$) of $\vec{\mathbf{F}}$.

2 STOKES' THEOREM

Relates the line integral around a closed curve to the surface integral of the curl over any oriented surface whose boundary is the curve.

Conditions
- S is an oriented surface of class C^1 with boundary C.
- $\mathbf{F}$ has continuous partial derivatives on an open region containing S.

THEOREM

$$\oint_C \vec{\mathbf{F}} \cdot d\vec{r} = \iint_S (\nabla \times \vec{\mathbf{F}}) \cdot \boldsymbol{n}\, dS$$

where $\vec{\boldsymbol{n}}$ is the unit normal vector to S, compatible with the orientation of C (right-hand rule).

Interpretation

The circulation of $\vec{\mathbf{F}}$ around C equals the flux of the curl of $\vec{\mathbf{F}}$ across S.

3 GAUSS' THEOREM (DIVERGENCE THEOREM)

Relates the outward flux of a vector field through a closed surface to the triple integral of the divergence of the field over the interior volume.

Conditions
- S is a closed surface of class C^1 oriented outward.
- $\vec{\mathbf{F}}$ has continuous partial derivatives on an open region containing the volume V.

THEOREM

$$\iint_S \vec{\mathbf{F}} \cdot \boldsymbol{n}\, dS = \iiint_V \nabla \cdot \vec{\mathbf{F}}\, dV$$

where $\vec{\boldsymbol{n}}$ is the unit outward normal vector on S.

Interpretation

The outward flux of $\vec{\mathbf{F}}$ through S equals the triple integral over V of the divergence of $\vec{\mathbf{F}}$ (net sources minus sinks).

4 DIVERGENCE THEOREM (GENERAL/INTEGRAL FORM)

A general form of Gauss' theorem, often called the divergence theorem.

Conditions
- S is a closed surface of class C^1 oriented outward.
- $\vec{\mathbf{F}}$ has continuous partial derivatives on an open region containing the volume V.

THEOREM

$$\iiint_V \nabla \cdot \vec{\mathbf{F}}\, dV = \iint_S \vec{\mathbf{F}} \cdot \boldsymbol{n}\, dS$$

where $\vec{\boldsymbol{n}}$ is the unit outward normal vector on S.

Interpretation

The total divergence of $\vec{\mathbf{F}}$ in V equals the outward flux of $\vec{\mathbf{F}}$ through the boundary S.

COMMON NOTATION
- $\vec{\mathbf{F}}$: vector field
- $\vec{r}$: position vector
- $\vec{\boldsymbol{n}}$: unit normal vector (outward unless stated otherwise)
- $d\vec{r}$: differential of a curve
- dS : differential of surface area
- dA : differential of area
- dV : differential of volume

KEY OPERATORS

Gradient : $\nabla f = \frac{\partial f}{\partial x}\boldsymbol{i} + \frac{\partial f}{\partial y}\boldsymbol{j} + \frac{\partial f}{\partial z}\boldsymbol{k}$

Curl : $\nabla \times \vec{\mathbf{F}} = \begin{vmatrix} \boldsymbol{i} & \boldsymbol{j} & \boldsymbol{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ F_x & F_y & F_z \end{vmatrix}$

Divergence : $\nabla \cdot \vec{\mathbf{F}} = \frac{\partial F_x}{\partial x} + \frac{\partial F_y}{\partial y} + \frac{\partial F_z}{\partial z}$

ORIENTATION (RIGHT–HAND RULE)

Point your right thumb in the direction of $\vec{\boldsymbol{n}}$. Your fingers curl in the positive direction of the boundary C.

6.6. Linear Algebra

THERE are several approaches to learn Linear Algebra. First a pragmatic way (we'll start with this one because our experience has shown us that it is the one that seemed to work best for students) and a more formal way that we will present in after. We should first warn the reader that linear algebra is a powerful calculation tool that we use enormous in economic and industrial practice in the following areas (see the respective chapters of the book for specific examples): Statistics , Electrical Engineering, Finance market, Numerical optimization methods, Optics, Quantum Physics, Electrodynamics, Relativity, Fluid mechanics, etc. It is then necessary to attach a special attention to this subject.

Remark

Linear algebra quietly underpins a surprising amount of what accountants and even low level financial analysts do because spreadsheet tools like Microsoft® Excel® rely on matrix-style (and vector) operations to process data efficiently! Array formulas, vectorized calculations, and functions such as the famous `SUMPRODUCT( )` essentially perform dot products between matrices and vectors. Understanding the linear algebra beneath these tools helps employees to design typical intermediate level spreadsheets calculations without constantly relying on quite expensive consultants that have an engineering or university degree with a linear algebra background.

First let us answer at two questions from a reader: Why Linear Algebra is named like this? And is there a Non-Linear Algebra?

Here are my answers:

1. This is named "Linear Algebra" because it was first necessary to choose a name... and also because it is a generalization of the scalar algebra but with vectors where applications are no longer scalar functions but matrix applications whose effect is to act as a linear sum of a base vectors (at least this can be interpreted as such).
2. Officially and to my knowledge there is no non-linear algebra in the same philosophy as what we will see in this section. It seem that they are mathematicians who have created "non linear algebra" but these have nothing to do with matrices.

Now, remember that we studied in section Calculus how to determine the intersection (if any exist) of the equation of two lines in $\mathbb{R}^2$ (we can extend the problem obviously to more than two lines), as it is equivalent to solve a polynomial of order 1, given by:

$$y_1 = a_1 x + b_1 \quad \text{and} \quad y_2 = a_2 x + b_2 \tag{6.6.1}$$

where $a_i, b_i \in \mathbb{R}$.

Thus seeking the value of x for which:

$$y_1=y_2 \tag{6.6.2}$$

leads us to write:

$$a_1x+b_1=a_2x+b_2 \Leftrightarrow x=\frac{b_1-b_2}{a_2-a_1} \tag{6.6.3}$$

However, there is another way of presenting the problem as we have seen in the Numerical Methods section (Theoretical Computer chapter). Indeed, we can write the problem in the form of a block of equations:

$$\begin{aligned} y_1&=a_1x+b_1\\ y_2&=a_2x+b_2 \end{aligned} \tag{6.6.4}$$

and as we seek $y_1=y_2=y$, we have:

$$\begin{aligned} y-a_1x&=b_1\\ y-a_2x&=b_2 \end{aligned} \tag{6.6.5}$$

This writing is named as we have seen in the chapter of Theoretical Computing (see section of Numerical Methods page 6304) a "linear system" that we can solve by subtracting or adding the lines between them (all the solutions are always equal), which gives us:

$$\begin{array}{r} y-a_1x=b_1\\ +y-a_2x=b_2\,|\cdot(-1)\\ \hline -a_1x+a_2x=b_1-b_2 \end{array} \tag{6.6.6}$$

and we see that we fall back on the solution:

$$x=\frac{b_1-b_2}{a_2-a_1} \tag{6.6.7}$$

So there are two ways to present a problem of intersection of lines:

1. In the form of an equation
2. In the form of a system

We will focus in a part of this section to the second method that will allow us with tools seen in the section of Vector Calculus to resolve not only the intersections of one or more straight lines but one or more straight, plans, hyperplanes, etc. in respectively $\mathbb{R},\mathbb{R}^2,\ldots,\mathbb{R}^n$.

Obviously we will see that Linear Algebra is not only use for this purpose but can also be used the generalized some physics mathematical models or to express geometrical transformations of vectors or figures in 2D or 3D or also express Markov Chains, special properties of Multivariate Statistics, calculation of some differential equation (for reliability engineering for example) and much more! Many examples are given in this textbook about the application of Linear Algebra in real life.

Before attacking the theoretical part, let us introduce a very interesting example but that requires a concept - the determinant - that we will prove rigorously much further in detail in this section (it seemed to us more pedagogical to approach this subject now rather than the reader must wait to browse dozens of pages of mathematical developments before reaching the rigorous definition of the determinant).

Consider the system of two linear equations with two unknowns (system of intersection of planes):

$$\begin{aligned} a_1x_1+b_1x_2&=c_1\\ a_2x_1+b_2x_2&=c_2 \end{aligned} \tag{6.6.8}$$

If we solve this, we quickly get (technique named "substitution method"):

$$\left.\begin{aligned} x_1&=\frac{c_1-b_1x_2}{a_1}\\ x_2&=\frac{c_2-a_2x_1}{b_2} \end{aligned}\right\} \Rightarrow x_1=\frac{c_1-b_1\left(\dfrac{c_2-a_2x_1}{b_2}\right)}{a_1}=\frac{b_2c_1-b_1c_2+b_1a_2x_1}{a_1b_2} \tag{6.6.9}$$

It comes then:

$$a_1b_2x_1-b_1a_2x_1=x_1(a_1b_2-b_1a_2)=b_2c_1-b_1c_2 \tag{6.6.10}$$

and so at the end:

$$x_1=\frac{b_2c_1-b_1c_2}{a_1b_2-b_1a_2} \tag{6.6.11}$$

and if we define a little bit fast something that is named the "determinant", that we will introduce further below rigorously, as follows:

$$\begin{aligned} D\left(\vec{c},\vec{b}\right)&=D\left(\begin{bmatrix} c_1 & b_1\\ c_2 & b_2\end{bmatrix}\right)=c_1b_2-c_2b_1\\ D\left(\vec{a},\vec{b}\right)&=D\left(\begin{bmatrix} a_1 & b_1\\ a_2 & b_2\end{bmatrix}\right)=a_1b_2-b_1a_2 \end{aligned} \tag{6.6.12}$$

or with another very more common notation:

$$\begin{aligned} \det\left(\vec{c},\vec{b}\right)&=|\vec{c},\vec{b}|=c_1b_2-c_2b_1\\ \det\left(\vec{a},\vec{b}\right)&=|\vec{a},\vec{b}|=a_1b_2-b_1a_2 \end{aligned} \tag{6.6.13}$$

we thus have:

$$x_1=\frac{c_1b_2-c_2b_1}{a_1b_2-a_2b_1}=\frac{\det\left(\vec{c},\vec{b}\right)}{\det\left(\vec{a},\vec{b}\right)} \tag{6.6.14}$$

And by proceeding in the same way we get:

$$\left.\begin{aligned} x_1&=\frac{c_1-b_1x_2}{a_1}\\ x_2&=\frac{c_2-a_2x_1}{b_2} \end{aligned}\right\} \Rightarrow x_2=\frac{c_2-a_2\left(\dfrac{c_1-b_1x_2}{a_1}\right)}{b_2}=\frac{a_1c_2-a_2c_1+a_2b_1x_2}{b_2a_1} \tag{6.6.15}$$

It comes then:

$$b_2a_1x_2-a_2b_1x_2=x_2(b_2a_1-a_2b_1)=a_1c_2-a_2c_1 \tag{6.6.16}$$

and so finally we get:

$$x_1=\frac{c_1b_2-c_2b_1}{a_1b_2-a_2b_1}=\frac{\det\left(\vec{c},\vec{b}\right)}{\det\left(\vec{a},\vec{b}\right)} \quad \text{and} \quad x_2=\frac{a_1c_2-a_2c_1}{a_1b_2-a_2b_1}=\frac{\det\left(\vec{a},\vec{c}\right)}{\det\left(\vec{a},\vec{b}\right)} \tag{6.6.17}$$

It then appears clear that if:

$$\det\left(\vec{a},\vec{b}\right)=\det\left(\vec{c},\vec{b}\right)=\det\left(\vec{a},\vec{c}\right)=0 \tag{6.6.18}$$

the system has infinitely many solutions. In contrast, the system has no solution if:

$$\det\left(\vec{a},\vec{b}\right)=0 \qquad \text{and} \qquad \left[\det\left(\vec{c},\vec{b}\right)\neq 0 \qquad \text{or} \qquad \det\left(\vec{a},\vec{c}\right)\neq 0\right] \tag{6.6.19}$$

And if the reader repeats (happily...) the procedure for a system of three equations with three unknowns of the type (intersection of hyperplanes):

$$\begin{aligned}a_1x_1+b_1x_2+c_1x_3&=d_1\\a_2x_1+b_2x_2+c_2x_3&=d_2\\a_3x_1+b_3x_2+c_3x_3&=d_3\end{aligned} \tag{6.6.20}$$

We then get (after some basic boring algebraic operations):

$$x_1=\frac{\det\left(\vec{d},\vec{b},\vec{c}\right)}{\det\left(\vec{a},\vec{b},\vec{c}\right)},x_2=\frac{\det\left(\vec{a},\vec{d},\vec{c}\right)}{\det\left(\vec{a},\vec{b},\vec{c}\right)},x_3=\frac{\det\left(\vec{a},\vec{b},\vec{d}\right)}{\det\left(\vec{a},\vec{b},\vec{c}\right)} \tag{6.6.21}$$

with:

$$\begin{aligned}\det\left(\vec{a},\vec{b},\vec{c}\right)&=a_1b_2c_3-a_1c_2b_3-b_1a_2c_3+b_1c_2a_3+c_1a_3b_3-c_1b_3a_3\\\det\left(\vec{d},\vec{b},\vec{c}\right)&=d_1b_2c_3-d_1c_2b_3-b_1d_2c_3+b_1c_2d_3+c_1d_2b_3-c_1b_2d_3\\\det\left(\vec{a},\vec{d},\vec{c}\right)&=a_1d_2c_3-a_1c_2d_3-b_1d_2c_3+b_1c_2d_3+c_1d_2b_3-c_1b_2d_3\\\det\left(\vec{a},\vec{b},\vec{d}\right)&=a_1b_2d_3-a_1d_2b_3-b_1a_2d_2+b_1d_2a_3+d_1a_2b_3-d_1b_2a_3\end{aligned} \tag{6.6.22}$$

It then appears clear that if:

$$\det\left(\vec{a},\vec{b},\vec{c}\right)=\det\left(\vec{d},\vec{b},\vec{c}\right)=\det\left(\vec{a},\vec{d},\vec{c}\right)=\det\left(\vec{a},\vec{b},\vec{d}\right)=0 \tag{6.6.23}$$

the system has infinitely many solutions. In contrast, the system has no solution if:

$$\det\left(\vec{a},\vec{b},\vec{c}\right)=0\text{ and }\left[\det\left(\vec{d},\vec{b},\vec{c}\right)\neq 0\text{ or }\det\left(\vec{a},\vec{d},\vec{c}\right)\neq 0\right] \tag{6.6.24}$$

and so on for n equations with n unknowns.

However, there was a condition to satisfy: as we have seen in the previous example, we could not solve a system of equations with two unknowns if we have only one equation. That is why it is necessary and sufficient for a system of equations with n unknowns to have at least n equations. Thus, we speak of "systems with n equations in n unknowns". We also prove that it is necessary and sufficient that the determinant is non-zero for a linear system, whose matrix equivalent is square, to have a unique solution (the concept of "determinant" and "matrix" will be defined further below robustly) and therefore that the corresponding matrix to the system is invertible (non-singular).

6.6.1 Linear Systems

Definitions (#6.6.251):

D1. We name "linear system", or simply "system" any family of equations of the form:

$$\begin{gathered}a_{11}x_1+a_{12}x_2+\ldots+a_{1n}x_n=b_1\\ a_{21}x_1+a_{22}x_2+\ldots+a_{2n}x_n=b_2\\ \ldots\\ a_{m1}x_1+a_{m2}x_2+\ldots+a_{mn}x_n=b_m\end{gathered} \tag{6.6.25}$$

where each line represents the equation of a line, plane or hyperplane (see section Analytical Geometry page 2800), and a_{mn} are the "system coefficients", the b_m the "coefficients of the second member" and the x_n the "unknowns of the system".

D2. If the system has n unknown and n equations and has a unique solution, we then name it a "Cramer system" (11750 according to holocene calendar).

D3. If the coefficients of the second member are all zero, then we say that the system is a "homogeneous system" so it has at least the trivial solution where all x_n are equal to zero. Otherwise we say that we have an "inhomogeneous system".

D4. We name "homogeneous system associated to the system", the system of equations we get by substituting zeros to the coefficients of the second member (b_m).

Let us now recall the following items:

- The linear equation (see section Functional Analysis page 2195) is given by:

$$a_1x_1+a_2x_2=b \tag{6.6.26}$$

  by defining $x=x_1$ and $y=x_2$.

- The equation of a plane (see section Analytical Geometry page 2800) is given by:

$$a_1x_1+a_2x_2+a_3x_3=b \tag{6.6.27}$$

  by defining $x=x_1,y=x_2,z=x_3$.

- The equation of a hyperplane is very easily (if you don't see how let us know we will specify it) generalizable from the demonstration of that of the plane and we then get:

$$a_1x_1+a_2x_2+\ldots+a_nx_n=b \tag{6.6.28}$$

  by defining $x=x_1,y=x_2,z=x_3,\ldots$

We often write a linear system in the following condensed form:

$$\boxed{\sum_{j=1}^{n} a_{ij}x_j = b_i \quad i = 1, 2, 3, \ldots, m} \tag{6.6.29}$$

We name "system solution" or "vector system solution" any t-uple $(x_1^0, x_2^0, \ldots, x_n^0)$ such as:

$$\sum_{j=1}^{n} a_{ij}x_j^0 = b_i \quad i = 1, 2, 3, \ldots, m \tag{6.6.30}$$

Solve a system means finding all the solutions of this system (we find many such systems in economic, operational research or design of experiments). Two system with n unknowns are named "equivalent systems" if all of the solution of one system is the solution of the other, i.e., if they have the same set of solutions. We sometimes say that the equations of a system are "compatible equations" or "incompatible equations", depending on whether the system has at least one solution or not admit any.

We can also give for sure a geometric interpretation to these systems. Suppose that the first members of the equations of the system are not zero. So we know that each of these equations represents a hyperplane of an affine space (see section Vector Calculus page 1815) of dimension n. Therefore, all solutions of the system, considered as set of n-tuples of coordinates is a finite intersection of hyperplanes.

✍**Example:**

Let us consider the following system of linear equations:

$$\left\{\begin{array}{rl} x_1 \qquad\quad - 3x_3 &= -3 \\ 2x_1 - 5x_2 - \;\; x_3 &= -2 \\ x_1 + 2x_2 - 5x_3 &= 1 \end{array}\right. \tag{6.6.31}$$

denoted conventionally in high-school classes in the form:

$$\left\{\begin{array}{rl} x \qquad\quad - 3z &= -3 \\ 2x - 5y - \;\; z &= -2 \\ x + 2y - 5z &= 1 \end{array}\right. \tag{6.6.32}$$

This system has for solutions the points representing the intersection of the three planes defined by the three equations. But as we can see it visually in Maple™ 4.00b using the following commands:

```
>with(plots):
>implicitplot3d(x-3*z=-3,2*x-5*y-z=-2,x+2*y-5*z=1,x=-3..3,
y=-3..3,z=-3..3);
```

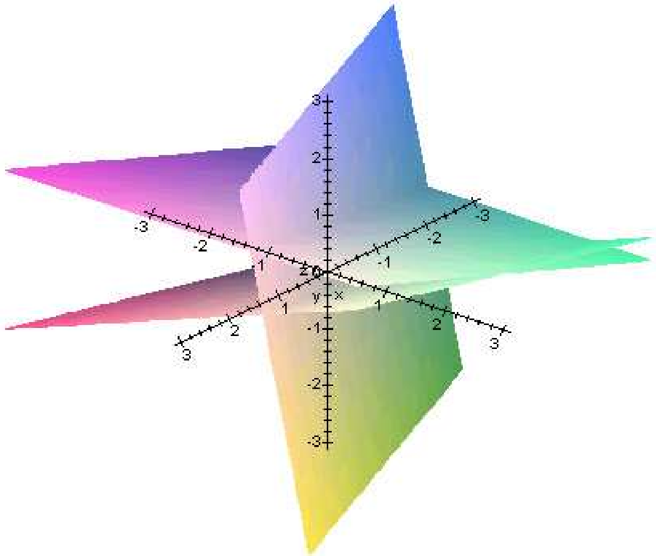

Figure 6.140: Graphical representation of the linear system with Maple™ 4.00b

There is no solutions. This can easily be checked by hand or in Maple™ 4.00b by writing:

```
>solve(x-3*z=-3,2*x-5*y-z=-2,x+2*y-5*z=1,x,y,z);
```

Remark

For "classic" resolution methods of such systems, we refer the readers to the section on Numerical Methods of the chapter on Computing Science.

Finally, note an important case in practice: "overdetermined systems" where we have more equations than unknowns.

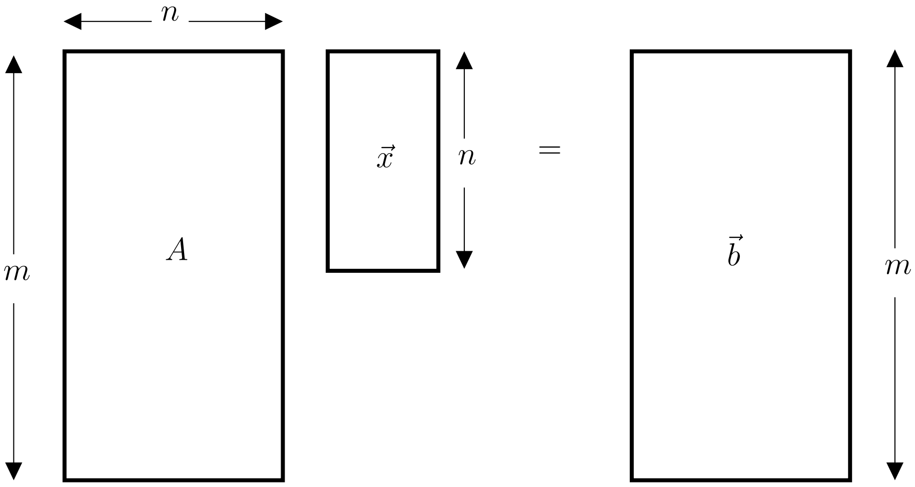

Figure 6.141: Overdetermined system

The first situation of this type dates from the 118th century (holocene calendar) through the study of the lunar oscillations but we also find this frequently in R&D laboratory in the context of design of experiments (see section Industrial Engineering page 8780) or in structural equation models (see section Numerical Methods).

An overdetermined system may be written as:

$$X\vec{b}\approx\vec{y} \tag{6.6.33}$$

where X is $n\times m$ and $\text{rank}(X\,|\,\vec{y})>m$; that is, the system is not consistent. We have changed the notation slightly from the consistent system $Ax=b$ that we have been using because now we have in mind statistical applications, and in those the notation $y\approx X\beta$ is more common. The problem is to determine a value of b that makes the approximation close in some sense. In applications of linear systems, we refer to this as "fitting" the system, which is referred to as a "model".

✍**Example:**

Consider the special case but very telling following example of three equations with two unknowns:

$$\begin{cases} 2x_1+x_2=-1 \\ -3x_1+x_2=-2 \\ -x_1+x_2=1 \end{cases} \tag{6.6.34}$$

System that will be written in the form of matrix and vector as following:

$$\begin{bmatrix} 2 & 1 \\ -3 & 1 \\ -1 & 1 \end{bmatrix}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix}=\begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix} \tag{6.6.35}$$

Or said in an "augmented form" as follows:

$$\left[\begin{array}{cc|c} 2 & 1 & -1 \\ -3 & 1 & -1 \\ -1 & 0 & 1 \end{array}\right] \tag{6.6.36}$$

and in Maple™ 4.00b:

```
>with(plots):
>implicitplot(2*x+3*y=-1,-3*x+y=-2,-x+y=1,x=-3..3,y=-3..3);
```

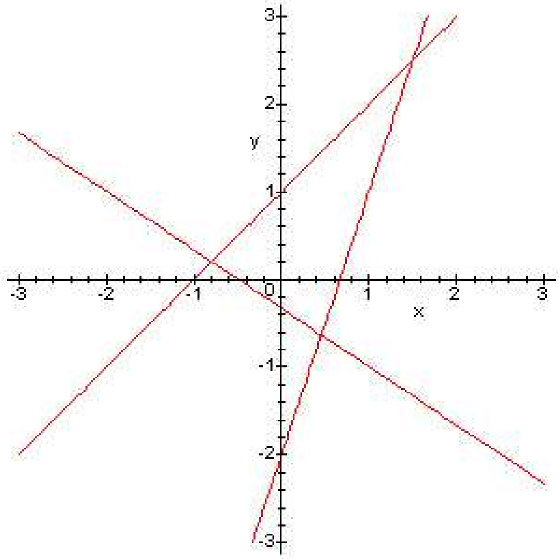

Figure 6.142: **Representation of a system of 3 equations with two unknowns in Maple™ 4.00b**

We can see on the chart above that this particular system has no complete solution but thus has a solution if we take only the problem by pair of equations... which does not necessarily help in facts...

Notice, that we have just seen that the system could be written as following:

$$\begin{bmatrix} 2 & 1 \\ -3 & 1 \\ -1 & 1 \end{bmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix} \tag{6.6.37}$$

This looks like a multiple linear regression system (see section of Numerical Methods page 6304) whose column vector of unknowns can be viewed as the coefficient vector $\vec{\beta}$ of the regression line such that:

$$\begin{bmatrix} 2 & 1 \\ -3 & 1 \\ -1 & 1 \end{bmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix} \Leftrightarrow X\vec{\beta}=\vec{y} \tag{6.6.38}$$

We then proved in detail in the section of Numerical Methods that:

$$\boxed{\hat{\vec{\beta}}=\left(X^TX\right)^{-1}X^T\vec{y}} \tag{6.6.39}$$

at the condition that the square matrix X^TX is, as we will see further below, invertible (non-singular). Since the works of Gauss on the subject it is considered that this approach (hence implicitly based on ordinary least squares regression[20]) remains even today the best approach to solve such systems!

If the invertible property is satisfied, we find a "pseudo-solution" (this is the official terminology...) by making calculations quickly by hand (or with a spreadsheet software like Microsoft®

---

[20] Such that we found $\vec{\beta}$ that minimize $\|X\vec{\beta}-\vec{y}\|^2$

Excel®):

$$\begin{pmatrix}\hat{\beta}_0\\ \hat{\beta}_1\end{pmatrix}=\begin{pmatrix}x_1\\ x_2\end{pmatrix}=\begin{pmatrix}-0.052\\ -0.368\end{pmatrix} \tag{6.6.40}$$

and injecting these values in the initial overdetermined system, the reader will quickly understand why we talk about "pseudo-solution"...

Remark

A reader asked us why we don't use for the example above just the relation $\vec{\beta}=\vec{y}X^{-1}$? The answer is simple! Because X is not a square matrix or in other words... it is in our example over-determined this is why we can only found a "pseudo-solution".

This was the pragmatic way of looking at it ... now let us turn to the second slightly more mathematical way ... (but still relatively simple):

6.6.2 Linear Transformations

Definition (#6.6.252): A "linear transformation" or "linear application" A is a mapping of a vector space E to a vector space F such that with K being in $\mathbb{R}$ or in $\mathbb{C}$:

$$\begin{aligned}\forall\vec{x}_1,\vec{x}_2\in E: &\quad A(\vec{x}_1+\vec{x}_2)=A\vec{x}_1+A\vec{x}_2\\ \forall\vec{x}\in E, a\in K: &\quad Aa\vec{x}=aA\vec{x}\end{aligned} \tag{6.6.41}$$

this constitutes, for recall, an endomorphism (see section Set Theory page 443).

The first property specifies that the transformation of a sum of vectors must be equal to the sum of the transformed vectors, so that it is linear. The second property specifies that the transformation of a vector to which we applied a scale factor (scaling) must also be equal to the same factor applied on the transformation of the original vector. If either of these two properties is not met, the transformation is therefore not linear.

We now show that any linear transformation can be represented by a matrix!

Given the basis vectors $(\vec{v}_1,\vec{v}_2,\ldots,\vec{v}_n)$ of E and $(\vec{u}_1,\vec{u}_2,\ldots,\vec{u}_n)$ for those of F with $m\geq n$. With these bases, we can represent any vectors $\vec{x}\in E,\vec{y}\in F$ with the following linear combinations (see section Vector Calculus page 1806):

$$\vec{x}=\sum_{j=1}^{n}x_j\vec{v}_j \qquad \vec{y}=\sum_{i=1}^{m}y_i\vec{u}_i \tag{6.6.42}$$

Consider the linear transformation A which applies E to F ($A:E\mapsto F$). So:

$$A(\vec{x})=\vec{y} \tag{6.6.43}$$

that we can rewrite as follows:

$$A\left(\sum_{j=1}^{n}x_j\vec{v}_j\right)=\sum_{i=1}^{m}y_i\vec{u}_i \tag{6.6.44}$$

But since A is a linear operator by definition, we can also write:

$$\sum_{j=1}^{n} x_j A(\vec{v}_j)=\sum_{i=1}^{m} y_i\vec{u}_i \qquad (6.6.45)$$

Considering now that the vectors $A(\vec{v}_j)$ are elements of F, we can rewrite them as a linear combination of its basis vectors:

$$A(\vec{v}_j)=\sum_{i=1}^{m} a_{ij}\vec{u}_i \qquad (6.6.46)$$

Therefore, we get:

$$\sum_{j=1}^{n} x_j A(\vec{v}_j)=\sum_{j=1}^{n} x_j\sum_{i=1}^{m} a_{ij}\vec{u}_i=\sum_{i=1}^{m} y_i\vec{u}_i \qquad (6.6.47)$$

By reversing the order of summations, we can write:

$$\sum_{i=1}^{m} \vec{u}_i\sum_{j=1}^{n} a_{ij}x_j=\sum_{i=1}^{m} y_i\vec{u}_i \qquad (6.6.48)$$

and rearranging the latter relation, we produce the result:

$$\sum_{i=1}^{m} \vec{u}_i\left(\sum_{j=1}^{n} a_{ij}x_j-y_i\right)=\vec{0} \qquad (6.6.49)$$

Finally, remembering that the basis vectors $\vec{u}_i$ must be independent, we can conclude that their coefficients must necessarily be zero, so:

$$\sum_{j=1}^{n} a_{ij}x_j=y_i \qquad (6.6.50)$$

Which corresponds to the "matrix product":

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix}\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}=\begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix} \qquad (6.6.51)$$

That we can write:

$$A\vec{x}=\vec{y} \qquad (6.6.52)$$

In other words, any linear transformation can be described by a matrix A that is multiplied with the vector that we want to transform, to get the vector resulting from the transformation.

6.6.3 Matrices

So we name a "matrix" with m rows and n columns, or "type $m \times n$ matrix" (the first term always correspond to the rows and the second to columns to the second, to remember this there is a good mnemonic trick: President Lincoln - abbreviation of Lin(e) and Col(um)n ...), any array of numbers in a ring $\mathbb{K}$ (that is most of times $\mathbb{R}$):

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1j} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2j} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & a_{ij} & \cdots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mj} & \cdots & a_{mn} \end{bmatrix} \tag{6.6.53}$$

For example:

$$\begin{array}{cc} & \text{\# columns} \\ \text{\# rows} & \begin{pmatrix} 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 1 \\ 1 & 1 & 0 & 0 & 1 \end{pmatrix} \end{array} \tag{6.6.54}$$

is a 5×5 matrix.

We often denote a matrix of type $m \times n$ briefly by:

$$(a_{ij})_{\substack{1\leq i\leq m \\ 1\leq j\leq n}} \in \mathbb{K} \tag{6.6.55}$$

or simply (a_{ij}). In a more formal way:

$$\mathbb{K}^{m\times n} = \left\{ \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1j} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2j} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & a_{ij} & \cdots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mj} & \cdots & a_{mn} \end{bmatrix} \middle| a_{ij} \in \mathbb{K} \forall i,j \right\} \tag{6.6.56}$$

The number a_{ij} is named "term or coefficient of index i,j". The index i is named the "line index" and the index j the "column index".

We denote by $M_{mn}(\mathbb{K})$ all matrices $m \times n$ whose coefficients take values in $\mathbb{K}$ (typically $\mathbb{R}$ or $\mathbb{C}$ for example).

When $m = n$, we say that (a_{ij}) is a "square matrix of order n":

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1j} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2j} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & a_{ij} & \cdots & \vdots \\ a_{m1} & a_{n2} & \cdots & a_{nj} & \cdots & a_{nn} \end{bmatrix} \tag{6.6.57}$$

In this case, the terms $a_{11}, a_{22}, \ldots, a_{nn}$ are named "diagonal terms" denoted by:

$$\text{diag}(a_1, \ldots, a_n) \tag{6.6.58}$$

We will assign to the matrices special symbols, i.e. uppercase Latin letters: $A, B, \ldots$ for matrices and for columns-matrices symbols that will be vectorial lowercase letters $\vec{a}, \vec{b}, \ldots$.

We also name a matrix with a single row a "line-matrix" and a matrix with a single column a "column-matrix". It is clear that a matrix column is nothing but a "column vector" or simply a "vector" (see section Vector Calculus page 1797). Thereafter, the rows of a matrix will be treated as lines-matrices and the columns to columns-matrices.

More formally, let $M \in \mathbb{R}^{m\times n}$ be a matrix, then a "submatrix" of M is a matrix which is made of some rectangle of elements in M. Rows and columns are submatrices! In particular:

- An $m \times 1$ submatrix is named a "column vector" of M. The j-th column vector is denoted $\text{col}_j(M)$ or $\vec{M}_j$ and $\vec{M}_{ji} = M_{ij}$ for $1 \leq j \leq n$. In other words:

$$\text{col}_j(M)=\vec{M}_j=\begin{pmatrix} a_{1j}\\ a_{2j}\\ \vdots\\ a_{mj}\end{pmatrix}\Rightarrow M=\begin{bmatrix} a_{11} & a_{21} & \cdots & a_{1n}\\ a_{21} & a_{22} & \cdots & a_{2n}\\ \vdots & \ldots & \ddots & \vdots\\ a_{m1} & a_{m1} & \cdots & a_{mn}\end{bmatrix}=[\text{col}_1(A)|\text{col}_2(A)|\ldots|\text{col}_n(A)] \tag{6.6.59}$$

- An $1 \times n$ submatrix of M is named a "row vector" of M. The i-th row vector is denoted $\text{row}_i(M)$ and $(\text{row}_i(M))_j = M_{ij}$ for $1 \leq i \leq m$ in other words:

$$\text{row}_i(M)=[a_{i1}\; a_{i2}\;\cdots\; a_{in}]\Rightarrow M=\begin{bmatrix} a_{11} & a_{21} & \cdots & a_{1n}\\ a_{21} & a_{22} & \cdots & a_{2n}\\ \vdots & \ldots & \ddots & \vdots\\ a_{m1} & a_{m1} & \cdots & a_{mn}\end{bmatrix}=\begin{pmatrix}\text{row}_1(M)\\ \text{row}_2(M)\\ \ldots\\ \text{row}_m(M)\end{pmatrix} \tag{6.6.60}$$

We name "zero matrix", and we denote by 0_{mn} or simply $\mathbf{0}$ or $\mathbb{O}$ (this last notation is preferred in this textbook!) any matrix in which each term is zero:

$$0_{mn}=\mathbf{0}=\mathbb{O}=\begin{bmatrix} 0 & 0 & 0 & \cdots & 0\\ 0 & 0 & 0 & \cdots & 0\\ 0 & 0 & 0 & \cdots & 0\\ \vdots & \vdots & \vdots & \ddots & \vdots\\ 0 & 0 & 0 & \cdots & 0\end{bmatrix} \tag{6.6.61}$$

Null columns-matrices are designated by the symbol vector: $\vec{0}$.

We name "identity matrix of order n" or "unit matrix of order n", and denote it by I_n, or simply $\mathbb{1}$, the following square matrix of order n:

$$I_n=\mathbb{1}=\begin{bmatrix} 1 & 0 & 0 & \cdots & 0\\ 0 & 1 & 0 & \cdots & 0\\ 0 & 0 & 1 & \cdots & 0\\ \vdots & \vdots & \vdots & \ddots & \vdots\\ 0 & 0 & 0 & \cdots & 1\end{bmatrix} \tag{6.6.62}$$

It can also be written using the Kronecker delta notation δ_{ij} (see section Tensors Calculus page 2044).

Caution! When we work with matrices having complex coefficients we must always use the term "identity matrix" rather than "unitary matrix" because in the field of complex numbers the unitary matrix is another mathematical object that should not be confused!

We will see later that the zero matrix acts as a neutral element of the matrix addition and the unit matrix as neutral element for the matrix multiplication.

The ij-th "standard basis matrix" for $\mathbb{R}^{m\times n}$ is denoted E_{ij} for $1\leq i\leq m$ and $1\leq j\leq n$. The matrix E_{ij} is zero in all entries except for the (i,j)-th slot where it has a 1. In other words, we define $(E_{ij})_{kl}=\delta_{ik}\delta_{jl}$. Hence every matrix in $\mathbb{R}^{m\times n}$ is a linear combination of the E_{ij}.

Indeed, let $M\in\mathbb{R}^{m\times n}$ then:

$$M=\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n}\\ a_{21} & a_{22} & \cdots & a_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ a_{m1} & a_{m2} & \cdots & a_{mn}\end{bmatrix}=a_{11}\begin{bmatrix} 1 & 0 & \cdots & 0\\ 0 & 0 & \cdots & 0\\ \vdots & \vdots & \ddots & 0\\ 0 & 0 & \cdots & 0\end{bmatrix}+a_{12}\begin{bmatrix} 0 & 1 & \cdots & 0\\ 0 & 0 & \cdots & 0\\ \vdots & \vdots & \ddots & 0\\ 0 & 0 & \cdots & 0\end{bmatrix}+\ldots+a_{mn}\begin{bmatrix} 0 & 0 & \cdots & 0\\ 0 & 0 & \cdots & 0\\ \vdots & \vdots & \ddots & 0\\ 0 & 0 & \cdots & 1\end{bmatrix}$$
$$=a_{11}E_{11}+a_{12}E_{12}+\ldots+a_{mn}E_{mn}=\sum_{i=1}^{m}\sum_{j=1}^{n}a_{ij}E_{ij} \tag{6.6.63}$$

The purpose of the concept of matrix will appear throughout the texts that will follow but the immediate reason for this notion is simply to allow some finite families of numbers to be designed as a rectangular array and to generalize physics theorems to multidimensional spaces.

6.6.3.1 Rank of a matrix

We will now briefly review the definition of "rank of a finite family" that we saw in the section of Vector Calculus at page 1813.

As a reminder we name "rank" of a free family of vectors the dimension (positive integer number) of the vector subspace S of E that it generates.

Definition (#6.6.253): Given $(\vec{a}_1,\vec{a}_2,\ldots,\vec{a}_n)$ the columns of a matrix A, we name "rank of A", and denote by $\text{rk}(A)$, the rank of the family of vectors $(\vec{a}_1,\vec{a}_2,\ldots,\vec{a}_n)$. More precisely, in linear algebra, the rank of a matrix A is the dimension of the vector space generated (or spanned) by its columns. This is the same as the dimension of the space spanned by its rows as we will see it later. It is a measure of the "nondegenerateness" of the system of linear equations and linear transformation encoded by A (see earlier above!). There are multiple equivalent definitions of rank. A matrix's rank is one of its most fundamental characteristics!

In a slightly more familiar language (...) the rank of a matrix is given by the number of columns-matrices that can't be expressed by the combination and scalar multiplication of other columns-matrices of the same matrix!!

Given this definition it is almost obvious that the rank of a matrix is zero if and only if the matrix is the zero matrix $\mathbb{O}$.

Before we enter in more formal calculations let us see already some introducing examples:

✍**Examples:**

E1. The matrix:

$$\begin{bmatrix} 1 & 2 & 1 \\ -2 & -3 & 1 \\ 3 & 5 & 0 \end{bmatrix} \tag{6.6.64}$$

has rank 2: the first two rows are linearly independent, so the rank is at least 2, but all three rows are linearly dependent (the first is equal to the sum of the second and third) so the rank must be less than 3.

E2. The matrix:

$$A = \begin{bmatrix} 1 & 1 & 0 & 2 \\ -1 & -1 & 0 & -2 \end{bmatrix} \tag{6.6.65}$$

has rank 1: there are non-zero columns, so the rank is positive, but any pair of columns is linearly dependent. Similarly, the transpose:

$$A^T = \begin{bmatrix} 1 & -1 \\ 1 & -1 \\ 0 & 0 \\ 2 & -2 \end{bmatrix} \tag{6.6.66}$$

of A has rank 1. Indeed, since the column vectors of A are the row vectors of the transpose of A, the statement that the column rank of a matrix equals its row rank is equivalent to the statement that the rank of a matrix is equal to the rank of its transpose, i.e.:

$$\boxed{\text{rk}(A) = \text{rk}(A^T)} \tag{6.6.67}$$

The above examples show the statement that the column rank of a matrix equals its row rank is equivalent to the statement that the rank of a matrix is equal to the rank of its transpose.

To summarize:

- Rank-0 Matrices. There is only one rank-zero matrix of a given size, namely the all-zero matrix.
- Rank-1 Matrices. A rank-one matrix is precisely a non-zero matrix of the type assumed in the example above - all rows are multiples of each other.

  An equivalent definition of a rank-1 $m \times n$ matrix is as the outer product $\vec{u}\vec{v}^T$ of an m-

vector $\vec{u}$ and an n-vector $\vec{v}$:

$$A=\vec{u}\vec{v}^T=\begin{bmatrix} - & u_1\vec{v}^T & - \\ - & u_2\vec{v}^T & - \\ & \vdots & \\ - & u_m\vec{v}^T & - \end{bmatrix}=\begin{bmatrix} | & | & & | \\ v_1\vec{u} & v_2\vec{u} & \cdots & v_n\vec{u} \\ | & | & & | \end{bmatrix} \tag{6.6.68}$$

Note that each row is a multiple of $\vec{v}^T$, and each column is multiple of $\vec{u}$.

- Rank-2 Matrices. A rank-two matrix is just a superposition (i.e., sum) of two rank-1 matrices:

$$A=\vec{u}\vec{v}^T+\vec{w}\vec{z}^\top=\begin{bmatrix} - & u_1\vec{v}^T+w_1\vec{z}^T & - \\ - & u_2\vec{v}^T+w_2\vec{z}^T & - \\ & \vdots & \\ - & u_m\vec{v}^T+w_m\vec{z}^T & - \end{bmatrix}=\begin{bmatrix} | & | \\ \vec{u} & \vec{w} \\ | & | \end{bmatrix}\cdot\begin{bmatrix} - & \vec{v}^T & - \\ - & \vec{z}^T & - \end{bmatrix} \tag{6.6.69}$$

- Rank-k Matrices. The general definition of matrix rank should now be clear: a matrix A has rank k if it can be written as the sum of k rank-one matrices, and cannot be written as the sum of $k-1$ or fewer rank-one matrices.

  Rephrased in terms of matrix multiplication, an equivalent definition is that A can be written as, or "factored into," the product of a long and skinny $(m\times k)$ matrix Y and a short and long $(k\times n)$ matrix Z^T (and that A cannot be likewise factored into the product of $m\times(k-1)$ and $(k-1)\times n$ matrices).

  There are many equivalent definitions of the rank of a matrix A. The following two conditions are equivalent to each other and to the definition above (any one of the three conditions implies the other two):

  1. The largest linearly independent subset of columns of A has size k. That is, all n columns of A arise as linear combinations of only k of them.
  2. The largest linearly independent subset of rows of A has size k. That is, all m rows of A arise as linear combinations of only k of them.

  It is clear that the first condition implies the second and third: if $A=YZ^T$, then all of A's columns are linear combinations of the k columns of Y, and all of A's rows are linear combinations of the k rows of Z^T.

Before continuing we would like to indicate to the reader that later we will prove that if the rows of a matrix are independent, its determinant (computable only for $n\times n$ square matrices) is non zero $\det(A)\neq 0$ and therefore $\text{rk}(A)=n$ and obviously $\text{rk}(A)=1$ when $\det(A)=0$.

Definition (#6.6.254): A matrix is said to have "full rank" if its rank equals the largest possible for a matrix of the same dimensions, which is the lesser of the number of rows and columns (i.e. $\text{rk}(A)=\min(m,n)$). A matrix is said to be "rank deficient" if it does not have full rank.

Remark

If there is difficulty in determining the rank of a matrix there is a technique named "matrix scaling" that we will see just below that can do this work very quickly.

Definition (#6.6.255): We name "system associated matrix":

$$\begin{aligned} a_{11}x_1+a_{12}x_2+\ldots+a_{1n}x_n&=b_1\\ a_{21}x_1+a_{22}x_2+\ldots+a_{2n}x_n&=b_2\\ &\ldots\\ a_{m1}x_1+a_{m2}x_2+\ldots+a_{mn}x_n&=b_m \end{aligned} \tag{6.6.70}$$

the mathematical object defined by:

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n}\\ a_{21} & a_{22} & \cdots & a_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix} \tag{6.6.71}$$

that is to say, the matrix A in which the terms are the coefficients of the system. We name "matrix of the second member of the linear system", or simply "second member of the system", the matrix-column $\vec{b}=(b_i)$ whose terms are the coefficients of the second member of this system. We also name "augmented matrix associated to a system" the matrix A obtained by adding $\vec{b}=(b_i)$ as the $(n+1)$-th column.

If we now consider an associated system matrix A and of second member $\vec{b}$. Let us always denote the columns of A by $(\vec{a}_1,\vec{a}_2,\ldots,\vec{a}_n)$. The system can then be written equivalently as a linear vector equation:

$$x_1\vec{a}_1+x_2\vec{a}_2+\ldots+x_n\vec{a}_n=\vec{b} \tag{6.6.72}$$

Now remember a theorem that we saw and proved in the section of Vector Calculus: for the rank of a family of vectors $(\vec{x}_1,\vec{x}_2,\ldots,\vec{x}_n)$ to be the equal to rank of augmented family $(\vec{x}_1,\vec{x}_2,\ldots,\vec{x}_n,\vec{y})$, it is necessary and sufficient that the vector $\vec{y}$ is a linear combination of the vectors $\vec{x}_1,\vec{x}_2,\ldots,\vec{x}_n)$.

It follows that our linear system in a vector form has at least one solution $(\vec{x}_1^0,\vec{x}_2^0,\ldots,\vec{x}_n^0)$ if the rank of the family $(\vec{a}_1,\vec{a}_2,\ldots,\vec{a}_n)$ is equal to the rank of augmented family $(\vec{a}_1,\vec{a}_2,\ldots,\vec{a}_n,\vec{b})$ and this solution is unique if and only if the rank of the family $(\vec{a}_1,\vec{a}_2,\ldots,\vec{a}_n)$ is equal to n.

Thus, for a linear system matrix of associated matrix A and of second member $\vec{b}$ admits at least one solution, it is necessary and sufficient that the rank of A is equal to the rank of the augmented matrix $(A|\vec{b})$. If this condition is met, the system admits a unique solution if and only if the rank of A is equal to the number of unknowns in other words: if the columns of A are linearly independent!!!

We say that a matrix is "staggered" if its rows (lines) meet the following two conditions:

C1. Any null line is followed by lines full of zeros

C2. The leading coefficient (the first non-zero number from the left, also named the "pivot") of a non-zero row is always strictly to the right of the leading coefficient of the row above it

These two conditions imply that all entries in a column below a leading coefficient are zeros.

A non-zero row echelon matrix is therefore of the form (by adding and subtracting rows between them):

$$\begin{bmatrix} \left|\underline{a_{1j_1}}\right. & \cdots & \cdots & a_{1n} \\ 0 & \left|\underline{a_{2j_2}}\right. & \cdots & a_{2n} \\ 0 & 0 & \left|\underline{a_{1j_r}}\right. & a_{rn} \\ 0 & 0 & 0 & 0 \end{bmatrix} \tag{6.6.73}$$

where $j_1 < j_2 < \ldots < j_r$ and $a_{1j_1}, a_{2j_2}, \ldots, a_{rj_r}$ are non-zero terms. The terminal zero lines may be missing.

The columns of index $j_1, j_2, \ldots, j_r$ of an echelon matrix are clearly linearly independent. Considered as vectors-columns of $\mathbb{R}^2$, so they form a basis of this vector space. Considering the other columns also as vectors-columns of $\mathbb{R}^n$, we deduce that they are necessarily linear combination of those of index $j_1, j_2, \ldots, j_r$ and therefore that the rank of the echelon matrix A is $\text{rk}(A) = r$.

We will note that r is also the number of non-zero lines of the echelon matrix and also the rank of the lines of this matrix, since the non-zero lines are therefore clearly independent (we proved in the section Vector Calculus that the rank of lines and columns has same value with the same properties of independence).

We can therefore allow ourselves to do a given number of elementary (extra) operations on the lines of matrices that we will be very useful, without changing its rank:

P1. We can swap the lines.

Remark

As we know the matrix can be seen just an aesthetic graphic representation of a linear system. So swap two lines does not change the system.

P2. Multiply a row by a non-zero scalar.

Remark

This obviously not altering the linear independence of the vectors lines.

P3. Adding to an original line, a multiple of another line.

Remark

The original line will disappear in favour of the new that is independent of all (former) others. The system thus remains linearly independent.

Any matrix can be transformed into a row echelon form by a finite sequence of the previous properties here's how:

1. Pivot the matrix
    (a) Find the pivot, the first non-zero entry in the first column of the matrix.
    (b) Interchange rows, moving the pivot row to the first row.
    (c) Multiply each element in the pivot row by the inverse of the pivot, so the pivot equals 1.
    (d) Add multiples of the pivot row to each of the lower rows, so every element in the pivot column of the lower rows equals 0.
2. To get the matrix in row echelon form, repeat the pivot.
    (a) Repeat the procedure from Step 1 above, ignoring previous pivot rows.
    (b) Continue until there are no more pivots to be processed.
3. To get the matrix in reduced row echelon form, process non-zero entries above each pivot.
    (a) Identify the last row having a pivot equal to 1, and let this be the pivot row.
    (b) Add multiples of the pivot row to each of the upper rows, until every element above the pivot equals 0.
    (c) Moving up the matrix, repeat this process for each row.

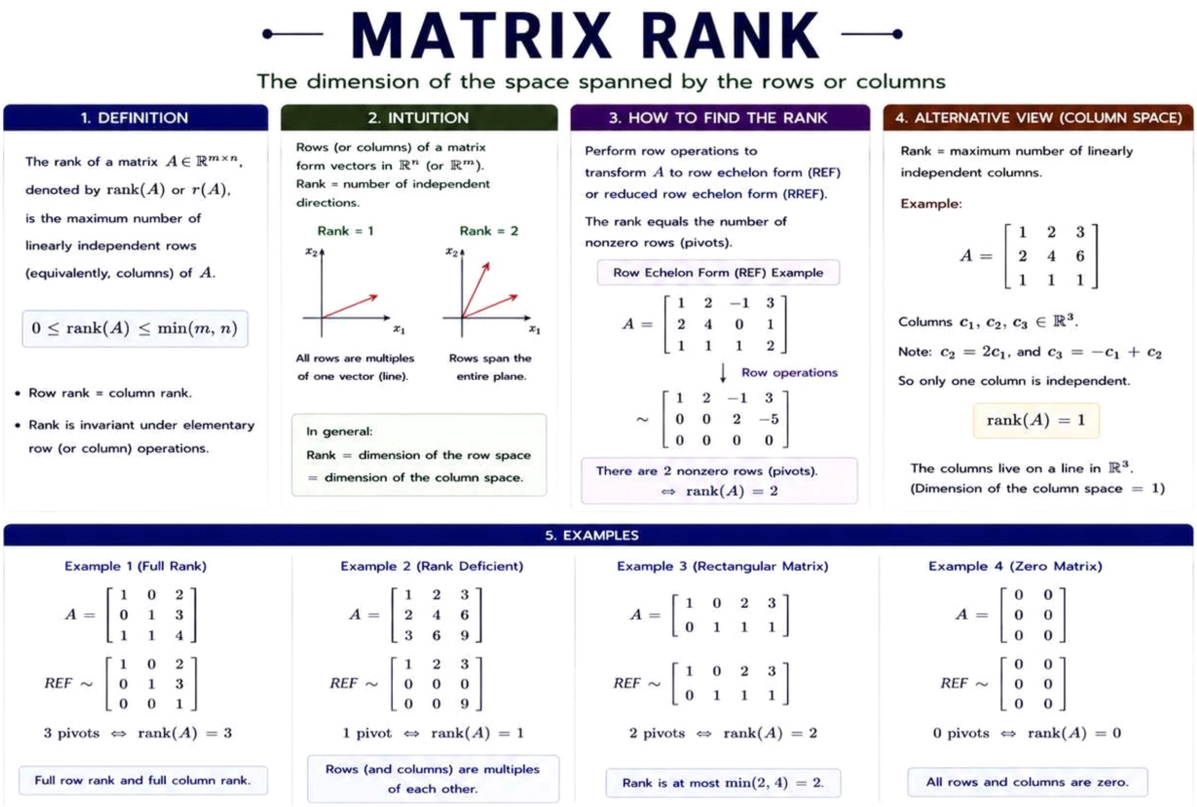
It is therefore obvious that the elementary operations on the rows of a matrix do not change the rank of the rows of the matrix. However, we know that the rank of lines of a row matrix is equal to the rank of the columns, that is to say to the rank of this matrix (once again see the section Vector Calculus for the proof). We conclude that the column rank of any matrix of the type $m\times n$ is also equal to the rank of the rows of this matrix.

As a corollary of this conclusion, it appears that:

$$\text{rk}(A)=\min(m,n) \tag{6.6.74}$$

When solving linear systems of m equation with n unknowns it appears, as we have already noted at the beginning of this section (and with practical example in the section of Numerical Methods), there must be at least an equal number of equations than unknowns or more rigorously: the number of unknowns must be less or equal to the number of equations such as:

$$\boxed{n=\text{rk}(A|\vec{b})\leq m} \tag{6.6.75}$$



MATRIX RANK

The dimension of the space spanned by the rows or columns

1. DEFINITION

The rank of a matrix $A \in \mathbb{R}^{m\times n}$, denoted by $\operatorname{rank}(A)$ or $r(A)$, is the maximum number of linearly independent rows (equivalently, columns) of A.

$$0 \le \operatorname{rank}(A) \le \min(m, n)$$

- Row rank = column rank.
- Rank is invariant under elementary row (or column) operations.

2. INTUITION

Rows (or columns) of a matrix form vectors in $\mathbb{R}^n$ (or $\mathbb{R}^m$). Rank = number of independent directions.

Rank = 1

All rows are multiples of one vector (line).

Rank = 2

Rows span the entire plane.

In general:
Rank = dimension of the row space
= dimension of the column space.

3. HOW TO FIND THE RANK

Perform row operations to transform A to row echelon form (REF) or reduced row echelon form (RREF).

The rank equals the number of nonzero rows (pivots).

Row Echelon Form (REF) Example

$$A = \begin{bmatrix} 1 & 2 & -1 & 3 \\ 2 & 4 & 0 & 1 \\ 1 & 1 & 1 & 2 \end{bmatrix}$$

$$\Big\downarrow \text{ Row operations}$$

$$\sim \begin{bmatrix} 1 & 2 & -1 & 3 \\ 0 & 0 & 2 & -5 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

There are 2 nonzero rows (pivots).
$\Leftrightarrow \operatorname{rank}(A) = 2$

4. ALTERNATIVE VIEW (COLUMN SPACE)

Rank = maximum number of linearly independent columns.

Example:

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \\ 1 & 1 & 1 \end{bmatrix}$$

Columns $c_1, c_2, c_3 \in \mathbb{R}^3$.

Note: $c_2 = 2c_1$, and $c_3 = -c_1 + c_2$

So only one column is independent.

$$\operatorname{rank}(A) = 1$$

The columns live on a line in $\mathbb{R}^3$.
(Dimension of the column space $= 1$)

5. EXAMPLES

Example 1 (Full Rank)

$$A = \begin{bmatrix} 1 & 0 & 2 \\ 0 & 1 & 3 \\ 1 & 1 & 4 \end{bmatrix}$$

$$REF \sim \begin{bmatrix} 1 & 0 & 2 \\ 0 & 1 & 3 \\ 0 & 0 & 1 \end{bmatrix}$$

$3 \text{ pivots} \Leftrightarrow \operatorname{rank}(A) = 3$

Full row rank and full column rank.

Example 2 (Rank Deficient)

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \\ 3 & 6 & 9 \end{bmatrix}$$

$$REF \sim \begin{bmatrix} 1 & 2 & 3 \\ 0 & 0 & 0 \\ 0 & 0 & 9 \end{bmatrix}$$

$1 \text{ pivot} \Leftrightarrow \operatorname{rank}(A) = 1$

Rows (and columns) are multiples of each other.

Example 3 (Rectangular Matrix)

$$A = \begin{bmatrix} 1 & 0 & 2 & 3 \\ 0 & 1 & 1 & 1 \end{bmatrix}$$

$$REF \sim \begin{bmatrix} 1 & 0 & 2 & 3 \\ 0 & 1 & 1 & 1 \end{bmatrix}$$

$2 \text{ pivots} \Leftrightarrow \operatorname{rank}(A) = 2$

Rank is at most $\min(2, 4) = 2$.

Example 4 (Zero Matrix)

$$A = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}$$

$$REF \sim \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}$$

$0 \text{ pivots} \Leftrightarrow \operatorname{rank}(A) = 0$

All rows and columns are zero.

6.6.3.2 Matrix Algebra

Remember that we saw during our study of Vector Calculus that the algebraic operations of multiplication of a vector by a scalar, addition or subtraction of vectors between them and the operation of scalar product formed in the context of set theory a "vector space" (see section Set Theory page 1805) possessing therefore a "vector algebraic structure". This under the condition that the vectors of course have the same dimensions (this observation, for recall, is not valid if instead of the scalar product we take the cross product).

Just as vectors, we can multiply a matrix by a scalar and add (subtract) them together (as long as they have the same dimensions..) but in addition, we can also multiply two matrices together under certain conditions which we will define below. This will also make the set of matrices in the set-sense, a vector space on K (being most of time $\mathbb{R}$) having also therefore a "vector algebraic structure".

Thus, a vector may also be viewed as a particular matrix of dimension $m \times n$ and operate in the vector space of matrices. Basically..., vector calculus is only a special case of linear algebra!!! This is way at school people learn (after Calculus) Vector Calculus first and Linear Algebra later (and some will lean after Tensor Calculus).

D1. Given $A,B \in M_{mn}(\mathbb{R})$. We name "sum of A and B" the matrix $C \in M_{mn}(\mathbb{R})$ whose coefficients are:

$$c_{ij} = a_{ij} + b_{ij} \qquad 1 \leq i \leq m, 1 \leq j \leq n \tag{6.6.76}$$

That is to say explicitly:

$$\begin{aligned}\begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & c_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ c_{m1} & c_{m2} & \cdots & c_{mn} \end{bmatrix} &= \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix} + \begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1n} \\ b_{21} & b_{22} & \cdots & b_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ b_{m1} & b_{m2} & \cdots & b_{mn} \end{bmatrix} \\ &= \begin{bmatrix} a_{11}+b_{11} & a_{12}+b_{12} & \cdots & a_{1n}+b_{1n} \\ a_{21}+b_{21} & a_{22}+b_{22} & \cdots & a_{2n}+b_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1}+b_{m1} & a_{m2}+b_{m2} & \cdots & b_{mm}+b_{mn} \end{bmatrix}\end{aligned} \tag{6.6.77}$$

D2. Given $A \in M_{mn}(\mathbb{R})$ a matrix and a $\lambda \in \mathbb{R}$ a scalar (we can also take in $\mathbb{C}$ if we want). We name "product of A by λ" the matrix whose coefficients are:

$$c_{ij} = \lambda a_{ij} \qquad 1 \leq i \leq m, 1 \leq j \leq n \tag{6.6.78}$$

That is to say explicitly:

$$\begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & c_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ c_{m1} & c_{m2} & \cdots & c_{mn} \end{bmatrix} = \lambda \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix} = \begin{bmatrix} \lambda a_{11} & \lambda a_{12} & \cdots & \lambda a_{1n} \\ \lambda a_{21} & \lambda a_{22} & \cdots & \lambda a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \lambda a_{m1} & \lambda a_{m2} & \cdots & \lambda a_{mn} \end{bmatrix} \tag{6.6.79}$$

With the two previous definitions we can actually conclude that the space / set of matrices is a vector space and thus has a vector algebraic structure.

D3. Let E, F, G be three vector spaces of basis respectively $\mathcal{E}, \mathcal{F}, \mathcal{G}$ and two linear application f and g (see the section Set Theory for a refresh).

Let us denote by A the matrix of f with respect to basis $\mathcal{E}, \mathcal{F}$, and B the matrix of g with respect to basis $\mathcal{F}, \mathcal{G}$. Then the matrix C of $g \circ f$ (see the definition of a composite function in the section of Functional Analysis) relating to the basis $\mathcal{E}, \mathcal{G}$ is equal to the product of B by A denoted simply by BA.

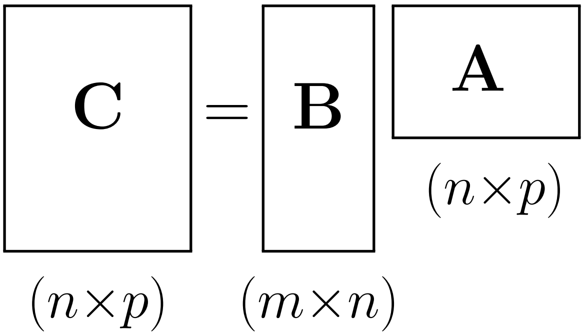
$$\begin{aligned} E \overset{f}{\mapsto} F \overset{g}{\mapsto} G \quad &\text{and} \quad E \overset{g\circ f}{\mapsto} G \\ E \overset{A}{\mapsto} F \overset{B}{\mapsto} G \quad &\text{and} \quad E \overset{BA=C}{\mapsto} G \end{aligned} \tag{6.6.80}$$

So let $B \in M_{mn} \in \mathbb{R}$ and $A \in M_{np} \in \mathbb{R}$, we name "matrix product" or "matrix multiplication" of A and B and we denote it by BA, the matrix $C \in M_{mp}\mathbb{R}$ whose components are:

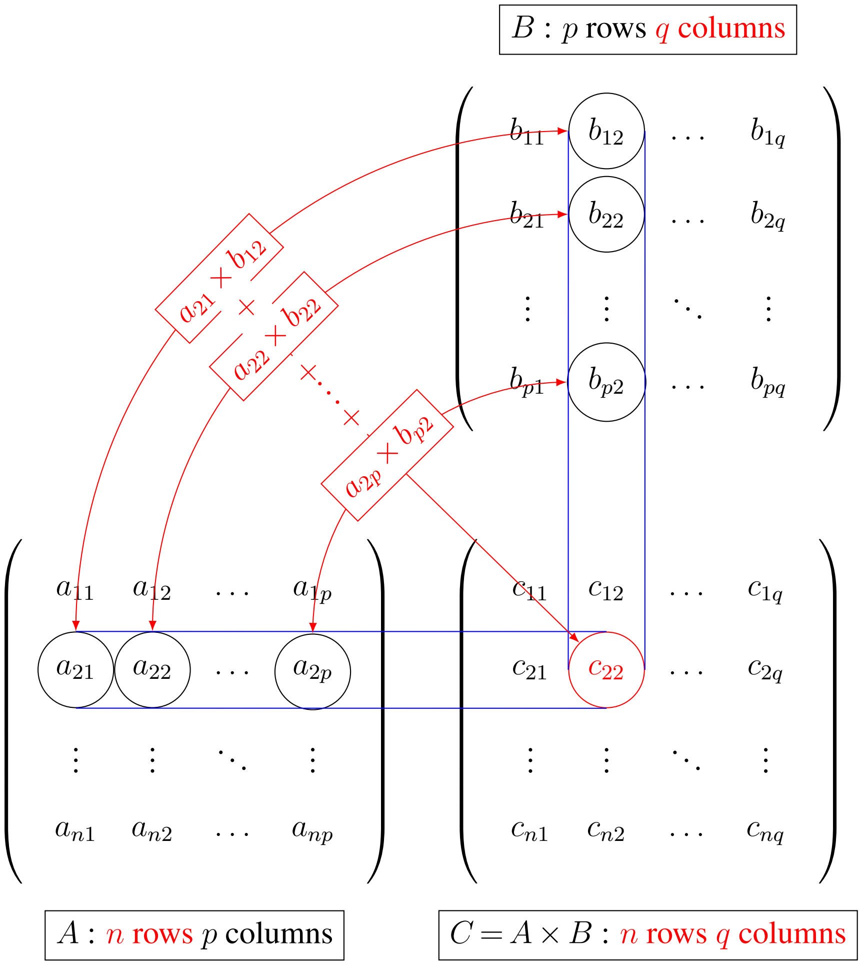
$$\boxed{c_{ki} = \sum_{j=1}^{n} b_{kj} a_{ji} \qquad 1 \leq i \leq p, 1 \leq k \leq m} \tag{6.6.81}$$

It is important to notice that at the opposite to the addition, A and B may have different dimensions. However! the number of rows of A must be equal to the number of columns of B, as indicated by the index n of the two matrices. So in the product BA, if B is a matrix $m \times n$, A must be a matrix $n \times p$, for any p!!!

Schematically:



or even more explicitly (Falk's scheme):



B : p rows q columns
b_{11} b_{12} … b_{1q}
b_{21} b_{22} … b_{2q}
b_{p1} b_{p2} … b_{pq}
$a_{21}\times b_{12}$
+
$a_{22}\times b_{22}$
+…+
$a_{2p}\times b_{p2}$
a_{11} a_{12} … a_{1p}
a_{21} a_{22} … a_{2p}
a_{n1} a_{n2} … a_{np}
c_{11} c_{12} … c_{1q}
c_{21} c_{22} … c_{2q}
c_{n1} c_{n2} … c_{nq}
A : n rows p columns
$C=A\times B$: n rows q columns

Figure 6.143: **Matrix product Falk's scheme (credit: Alain Matthes)**

By denoting with a capital Latin letters matrices and with lowercase Greek letters scalars, the reader can easily verify with what we have seen until now (we can add proofs on request) the following properties of matrix algebra (the matrices are assumed to have adequate dimensions):

P1. Left distributivity: $A(B+C)=AB+AC$

P2. Right distributivity: $(A+B)C=AC+BC$

P3. Scaling association: $(\lambda A)B=A(\lambda A)$

P4. Associativity: $(AB)C=A(BC)$

P5. Non-commutativity: $BA\neq AB$

P6. Absorbing-Element: $A\mathbb{O}=\mathbb{O}$

P7. Neutral Element for addition: $A+\mathbb{O}=A$

It is especially important to remember the property P5 that shows that the multiplication is obviously not commutative (for dimensions greater than 1 of course!) and also the property P4 such that the matrix multiplication is associative.

Concerning the general proof that the assertion of commutativity if false we must pass through a numerical example (because even the general case without replacing algebraic terms by numerical values will not show you much in our point of view...).

Remark

The set of square matrices $M_{nn} \in \mathbb{R}$ of order n with components in $\mathbb{R}$ provided with the sum and the usual matrix multiplication forms a ring (see section Set Theory page 426). This is true more generally if the coefficients of the matrices are taken in any ring: for example, all the matrices $M_{nn} \in \mathbb{Z}$ with integer components is a ring.

One reader asked us to prove the property of associative. So let us begin!

Let $A \in M_{kl}(\mathbb{C}), B \in M_{lm}(\mathbb{C}), C \in M_{mn}(\mathbb{C})$, then for $1 \leq i \leq k, 1 \leq j \leq n$, we have well (we use the explicit expression of matrix components multiplication seen above many times as you can see):

$$\begin{aligned}(A(BC))_{ij} &= \sum_{p=1}^{l} A_{ip}(BC)_{pj} = \sum_{p=1}^{l} A_{ip}\left(\sum_{q=1}^{m} B_{pq}C_{qi}\right) = \sum_{p=1}^{l}\sum_{q=1}^{m} A_{ip}B_{pq}C_{qi}\\ &= \sum_{q=1}^{m}\left(\sum_{p=1}^{l} A_{ip}B_{pq}\right)C_{qj} = \sum_{q=1}^{m}(AB)_{iq}C_{qj} = \sum_{q=1}^{m}(AB)_{iq}C_{qj} = ((AB)C)_{ij}\end{aligned} \tag{6.6.82}$$

6.6.3.3 Type of Matrices

To simplify the notations and length of calculations we introduce now the most common types of matrices that the reader will encounter throughout his reading of this textbook (and not just in the chapters on pure mathematics!).

Some definitions will only be recalls!

We denote by $M_{mn}(\mathbb{K})$ all matrices $m \times n$ whose coefficients take values in K (typically $\mathbb{R}$ or $\mathbb{C}$ for example).

Definitions (#6.6.256):

D1. When $m = n$, we say that $M_{nn}(\mathbb{K}) = (a_{ij})$ is a "square matrix of order n":

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1j} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2j} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & a_{ij} & \cdots & \vdots \\ a_{m1} & a_{n2} & \cdots & a_{nj} & \cdots & a_{nn} \end{bmatrix} \tag{6.6.83}$$

D2. We name "zero matrix", and we denote by 0_{mn} or simply $\mathbf{0}$ or $\mathbb{O}$ (this last notation is preferred in this textbook!) any matrix in which each term is zero:

$$0_{mn}=\mathbf{0}=\mathbb{O}=\begin{bmatrix}0&0&0&\cdots&0\\0&0&0&\cdots&0\\0&0&0&\cdots&0\\\vdots&\vdots&\vdots&\ddots&\vdots\\0&0&0&\cdots&0\end{bmatrix} \tag{6.6.84}$$

Null columns-matrices are designated by the symbol vector: $\vec{0}$.

D3. We name "identity matrix of order n" or "unit matrix of order n", and denote it by I, or simply $\mathbb{1}$, the square matrix of order n:

$$I_n=\mathbb{1}=\begin{bmatrix}1&0&0&\cdots&0\\0&1&0&\cdots&0\\0&0&1&\cdots&0\\\vdots&\vdots&\vdots&\ddots&\vdots\\0&0&0&\cdots&1\end{bmatrix} \tag{6.6.85}$$

It can also be written using the Kronecker delta notation δ_{ij} (see section Tensors Calculus page 2044).

Remark

Even if we use it actually for only two practical applications in this textbook (Principal Component Analysis and Multidimensional Scaling), and that we don't found it often in other textbooks, the latter definition must not be confuse we the matrix named "matrix of ones", and defined for a square $n\times n$ matrix by:

$$\mathbb{J}=\begin{bmatrix}1&1&1&\cdots&1\\1&1&1&\cdots&1\\1&1&1&\cdots&1\\\vdots&\vdots&\vdots&\ddots&\vdots\\1&1&1&\cdots&1\end{bmatrix} \tag{6.6.86}$$

D4. We name "diagonal matrix" any square matrix $A\in M_{nn}\in\mathbb{C}$ which only the diagonal has non-null elements:

$$A=\begin{bmatrix}a_{11}&0&0&\cdots&0\\0&a_{22}&0&\cdots&0\\0&0&a_{33}&\cdots&0\\\vdots&\vdots&\vdots&\ddots&\vdots\\0&0&0&\cdots&a_{nn}\end{bmatrix} \tag{6.6.87}$$

Formally:

$$\forall i,j\in\{1,n\}:\quad i\neq j\Rightarrow a_{ij}=0 \tag{6.6.88}$$

The usual notation of a diagonal matrix is:

$$D=\text{diag}\,\{a_{11},a_{22},\ldots,a_{nn}\}:=\text{diag}\,\{d_1,d_2,\ldots,d_n\} \tag{6.6.89}$$

D5. We name "lower triangular matrix" a square matrix if all the entries above the main diagonal are zero:

$$\begin{bmatrix} a_{11} & 0 & 0 & 0 & 0 & 0 \\ a_{21} & a_{22} & 0 & 0 & 0 & 0 \\ \vdots & \vdots & \ddots & a_{ij} & 0 & 0 \\ a_{m1} & a_{n2} & \cdots & a_{nj} & \cdots & a_{nn} \end{bmatrix} \tag{6.6.90}$$

Formally:

$$\forall i,j \in \{1,n\}: \quad i<j \Rightarrow a_{ij}=0 \tag{6.6.91}$$

Similarly, a square matrix is named "upper triangular matrix" if all the entries below the main diagonal are zero:

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1j} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2j} & \cdots & a_{2n} \\ 0 & 0 & 0 & a_{ij} & \cdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & a_{nn} \end{bmatrix} \tag{6.6.92}$$

Formally:

$$\forall i,j \in \{1,n\}: \quad j<i \Rightarrow a_{ij}=0 \tag{6.6.93}$$

A "triangular matrix" is one that is either lower triangular or upper triangular. A matrix that is both upper and lower triangular is named a "diagonal matrix".

If an upper triangular matrix was obtained by a "staggered" matrix we will write it as following:

$$\begin{bmatrix} \left|\underline{a_{1j_1}}\right. & \cdots & \cdots & a_{1n} \\ 0 & \left|\underline{a_{2j_2}}\right. & \cdots & a_{2n} \\ 0 & 0 & \left|\underline{a_{1j_r}}\right. & a_{rn} \\ 0 & 0 & 0 & 0 \end{bmatrix} \tag{6.6.94}$$

D6. A "Toeplitz matrix" (named after Otto Toeplitz) or "diagonal-constant matrix", is a matrix in which each descending diagonal from left to right is constant. For instance, the following matrix is a Toeplitz matrix:

$$\begin{bmatrix} a & b & c & d & e \\ f & a & b & c & d \\ g & f & a & b & c \\ h & g & f & a & b \\ i & h & g & f & a \end{bmatrix} \tag{6.6.95}$$

Any $n \times n$ matrix A of the form:

$$A = \begin{bmatrix} a_0 & a_{-1} & a_{-2} & \cdots & \cdots & a_{-(n-1)} \\ a_1 & a_0 & a_{-1} & \ddots & & \vdots \\ a_2 & a_1 & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & a_{-1} & a_{-2} \\ \vdots & & \ddots & a_1 & a_0 & a_{-1} \\ a_{n-1} & \cdots & \cdots & a_2 & a_1 & a_0 \end{bmatrix} \tag{6.6.96}$$

is a Toeplitz matrix. If the i,j element of A is denoted $A_{i,j}$, then we have:

$$A_{i,j}=A_{i+1,j+1} \tag{6.6.97}$$

We will meet such a matrix in our study of time series analysis and especially when we will prove the Yule-Walker equations (see section Social Sciences page **??**).

D7. Given M_{nn} a square matrix. The matrix M_{nn} is named "invertible matrix" or "regular matrix" or "non-singular matrix" if and only if M_{nn}^{-1} is such that:

$$M_{nn}M_{nn}^{-1}=I_n=\mathbb{1} \tag{6.6.98}$$

If this is not the case, we say that M_{nn} is a "singular matrix". We will prove later that for a square matrix to invertible (non-singular) on sufficient condition is that its determinant is equal to zero.

This definition is fundamental, it has extremely important consequences in all linear algebra and also in physics (solving linear systems, determining, eigenvectors and eigenvalues, etc.), statistics and finance and it is appropriate to remember it.

Let us prove a useful property of invertible matrices associated with the property of associativity of matrix multiplication:

$$(AB)^{-1}=B^{-1}A^{-1} \tag{6.6.99}$$

Indeed:

$$(AB)\left(B^{-1}A^{-1}\right)=\left(A\left(BB^{-1}\right)\right)A^{-1}=(A\mathbb{1})A^{-1}=AA^{-1}=\mathbb{1} \tag{6.6.100}$$

D8. Given a matrix $A_{mn}:=A$:

$$A=\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n}\\ a_{21} & a_{22} & \cdots & a_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ a_{m1} & a_{m2} & \cdots & a_{mn}\end{bmatrix} \tag{6.6.101}$$

We name "transposed matrix" of $A=A_{mn}$, the matrix denoted by $A^T=A_{nm}$ (the superscript T is depending of the books and teachers uppercase or lowercase and either left or right but the standard ISO 80000-2:2009 *Mathematical signs and symbols to be used in the natural sciences and technology* recommends the capital and superscript on the top right[21]) for which we transpose the rows into columns and the into rows:

$$A^T=\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m}\\ a_{21} & a_{22} & \cdots & a_{2m}\\ \vdots & \vdots & \ddots & \vdots\\ a_{n1} & a_{n2} & \cdots & a_{nm}\end{bmatrix} \tag{6.6.102}$$

Here are some interesting properties of the transpose of a matrix (which we will be useful to us later in this section for a famous theorem and also in the study of the multiple linear regression methods in the section of Numerical Methods!):

---

[21] Sadly many textbooks, especially from USA denoted the transpose with a prime: A'

P1. $(A^T)^T$
P2. $(\lambda A+B)^T=\lambda A^T+B^T, \lambda\in\mathbb{R}, \lambda\in\mathbb{R}$
P3. $(AB)^T=B^TA^T$
P4. $(A^{-1})^T=(A^T)^{-1}, \exists A^{-1}$
P5. $A\vec{x}\circ\vec{y}=\vec{x}A^T\vec{y}$

The transposed matrix is very important in physics, statistics and finance and obviously in the field of mathematics for example in the context of the theory of groups and symmetries! So it is also worth remembering its definition.

As the third property is the most used one in the various sections of this textbook let us demonstrate it by considering $A\in M_{lm}\in\mathbb{C}, B\in M_{mn}\in\mathbb{C}$:

Proof 6.37.6. Remembering the explicit relation of matrix multiplication seen earlier:

$$(B^TA^T)_{ij}=\sum_{i=1}^{m}(B^T)_{ik}(A^T)_{kj}=\sum_{k=1}^{m}B_{ki}A_{jk} \tag{6.6.103}$$

But in this last equality, we note that we browse B by line and A in column for a i and a j fixed and this we know then corresponds to the matrix multiplication AB, therefore:

$$(B^TA^T)_{ij}=\sum_{k=1}^{m}B_{ki}A_{jk}=(AB)_{ji}=((AB)^T)_{ij} \tag{6.6.104}$$

Finally we have well:

$$((AB)^T)_{ij}=(B^TA^T)_{ij} \tag{6.6.105}$$

■ Q.E.D.

And for the same reasons let us prove the before last property.

Proof 6.37.7. First, it is trivial that if A is invertible:

$$AA^{-1}=I_n \tag{6.6.106}$$

and taking the transpose on both sides of the equality we find (we use the property proved just before):

$$(A^{-1})^TA^T=I_n \tag{6.6.107}$$

The latter equality shows obviously that $(A^{-1})^T$ is the inverse of A^T, that is to say:

$$(A^{-1})^T=(A^T)^{-1} \tag{6.6.108}$$

■ Q.E.D.

Finally, a last and important property of transposed matrices, is that given a matrix A (square or not, symmetric or not), the multiplication by it's own transposed gives a symmetric matrix.

The proof is quite straightforward and very useful for the SVD (Singular Value Decomposition) theorem:

$$(AA^T)^T=(A^T)^TA^T=AA^T \tag{6.6.109}$$

D9. Given:

$$A=\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix} \qquad (6.6.110)$$

a matrix of $M_{mn}(\mathbb{C})$. We name "adjoint matrix" of A, the matrix of $M_{mn}(\mathbb{C})$ defined by:

$$\bar{A}^T=\begin{bmatrix} \bar{a}_{11} & \bar{a}_{12} & \cdots & \bar{a}_{1n} \\ \bar{a}_{21} & \bar{a}_{22} & \cdots & \bar{a}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \bar{a}_{m1} & \bar{a}_{m2} & \cdots & \bar{a}_{mn} \end{bmatrix} \qquad (6.6.111)$$

which is the complex conjugate of the transposed matrix or if you prefer ... the transposed matrix of the complex conjugate (in the case of real components... we obviously don't need to take the conjugate!). To simplify the notations we simply note this matrix $A^\dagger$ (notation frequently use in Quantum Physics and Set Algebra).

Remark

Trivial relation (which is often used in Quantum Field Physics) already proved just before and obviously correct when the components are in $\mathbb{C}$:

$$(AB)^\dagger=B^\dagger A^\dagger \qquad (6.6.112)$$

D10. By definition, a matrix is named "Hermitian matrix" or "self-adjoint matrix"... if it is equal to its own adjoint (conjugate transpose matrix) such that:

$$A=A^\dagger \qquad (6.6.113)$$

D11. Given A as square matrix $M_{nn}(\mathbb{R})$, the "trace" of A denoted $\text{tr}(A)$ is defined by the sum of the terms of the diagonal (very useful in some statistical techniques):

$$\boxed{\text{tr}(A)=\sum_{i=1}^{m} a_{ij}} \qquad (6.6.114)$$

Some useful related relations (we can add the detailed proof on the demand of the readers):

$$\text{tr}(\lambda A+B)=\lambda\text{tr}(A)+\text{tr}(B) \qquad (6.6.115)$$

and:

$$\text{tr}(AB)=\text{tr}(BA) \quad \forall A\in M_{mn}(\mathbb{R}),\forall B\in M_{nm}(\mathbb{R}) \qquad (6.6.116)$$

D12. A matrix A is named "nilpotent matrix" if by multiplying it successively by itself it can give zero. Explicitly, if there exists an integer k such that:

$$A^k=0 \qquad (6.6.117)$$

If the matrix A multiplied by itself gives A ... then we talk about an "idempotent matrix".

Such matrices are for example very common in Markov Chains when the transition matrix contains probabilities (see the sections of Probabilities and Graph Theory).

Remark

To remember this name, we can decompose it into "nil" that means "zero" and "potent" that means "potential". So something "nilpotent" is therefore something that is potentially zero....

D13. A matrix A is named "orthogonal matrix" if its elements are real and if it obeys to:

$$A^{-1}=A^T \tag{6.6.118}$$

which can be translate into (where δ_{ij} the Kronecker symbol):

$$A^TA=AA^T=\mathbb{1}=[\delta_{ij}] \tag{6.6.119}$$

The matrix column vectors A_i are thus orthogonal to each other as the resulting operation above can be seen as a row-column dot product such that for a $n\times n$ squared matrix:

$$\sum_{i=1}^{n}A_{ik}A_{in}=\delta_{kn} \qquad 1\leq k\leq n \tag{6.6.120}$$

Therefore an orthogonal matrix represents also an orthogonal basis!

Remark

When numerical data are stored in the usual way in a matrix X, the matrix X^TX, and its properties often plays an important role in statistical analysis and especially in regression techniques. A matrix of this form is named a "Gramian matrix".

A typical mathematical example is the matrix of the canonical orthonormal basis (see section Vector Calculus page 1810):

$$A=\begin{bmatrix}1&0&0\\0&1&0\\0&0&1\end{bmatrix} \tag{6.6.121}$$

or a well known matrix in quantum physics (see section Quantum Computing page 7291):

$$A=\begin{bmatrix}-\dfrac{1}{\sqrt{2}}&\dfrac{1}{\sqrt{2}}\\\dfrac{1}{\sqrt{2}}&\dfrac{1}{\sqrt{2}}\end{bmatrix} \tag{6.6.122}$$

Remarks

R1. Therefore this is typically the case of the canonical basis matrix, or any diagonalized matrix.

R2. If instead of just taking a matrix with real coefficients, we take complex coefficients with its complex transposed matrix (adjoint matrix), then we say (sadly... because it makes confusion with the name of another matrix already defined) that A is a "unitary matrix" if it satisfies the previous relation!

We will come back later, after having introduced the concepts of eigenvectors and eigenvalues, a particular and very important case of orthogonal matrices (named "translations matrices").

Let us also mention another important property in geometry, physics and statistics of orthogonal matrices.

Theorem 6.38. Given $f(\vec{x})=A\vec{x}+\vec{b}$, where A is an orthogonal matrix and $\vec{b}\in\mathbb{R}^n$. Then f (respectively A) is an isometry. That is to say:

$$\|f(\vec{x})-f(\vec{y})\|=\|\vec{x}-\vec{y}\| \quad \forall\vec{x},\vec{y}\in\mathbb{R}^n \tag{6.6.123}$$

So in other words: Orthogonal matrices are linear mappings which preserve the norm (the distance)!!!

Proof 6.38.1. Remembering that $\vec{x}\circ\vec{y}$ is the same in linear algebra notation as $\vec{x}^T\vec{y}$ we then have:

$$\begin{aligned}\|f(\vec{x})-f(\vec{y})\|^2&=(f(\vec{x})-f(\vec{y}))\circ(f(\vec{x})-f(\vec{y}))=(A\vec{x}-A\vec{y})\circ(A\vec{x}-A\vec{y})\\&=A(\vec{x}-\vec{y})\circ A(\vec{y}-\vec{y})=(A^TA(\vec{x}-\vec{y}))\circ(\vec{x}-\vec{y})=(\vec{x}-\vec{y})\circ(\vec{x}-\vec{y})\end{aligned} \tag{6.6.124}$$

and we have well:

$$\|f(\vec{x})-f(\vec{y})\|=\|\vec{x}-\vec{y}\| \tag{6.6.125}$$

■ Q.E.D.

D14. Given a square matrix $A\in M_{nn}$. The matrix A is named "symmetric matrix" if and only if:

$$A^T=A\Leftrightarrow a_{ij}=a_{ji} \tag{6.6.126}$$

We will meet this definition again in the section of Tensor Calculus.

D15. Given a square matrix $A\in M_{nn}$. The matrix A is named "antisymmetric matrix" (also sometimes named "skew-symmetric matrix"...) if and only if:

$$a_{ij}=-a_{ji} \tag{6.6.127}$$

which requires that:

$$a_{11}=a_{22}=\ldots=a_{mm}=0 \tag{6.6.128}$$

In electromagnetism the electromagnetic field tensor has components which can be written as an antisymmetric 4×4 matrix. In classical mechanics, a solid's propensity to spin in various directions is described by the inertia tensor which is symmetric. The energy-momentum tensor from electrodynamics is also symmetric. Most metric in Einstein field equations in General Relativity are symmetric but we can also build antisymmetric metrics. Matrices are everywhere if look for them.

Remark

We will prove in the section of Tensor Calculus (page 2088) that every square matrix are formed by the sum of a symmetric and antisymmetric matrix.

D16. Let E be a vector space of dimension n and $\mathcal{B},\mathcal{B}'$ two basis of E:

$$\mathcal{B}(\vec{e}_1,\vec{e}_2,\ldots,\vec{e}_n),\mathcal{B}'(\vec{e}_1',\vec{e}_2',\ldots,\vec{e}_n') \tag{6.6.129}$$

We name "transition matrix" of the basis $\mathcal{B}$ to the basis $\mathcal{B}'$, and we denote by P the square matrix of $M_{nn}(\mathbb{K})$ which columns are formed of components of vectors of the basis $\mathcal{B}'$ on the basis $\mathcal{B}$ (see further below the detailed treatment of basis changes for more information).

We consider the vector $\vec{x}(x_1,x_2,\ldots,x_n)$ of E which is written in the basis $\mathcal{B}(\vec{e}_1,\vec{e}_2,\ldots,\vec{e}_n)$ and $\mathcal{B}'(\vec{e}_1',\vec{e}_2',\ldots,\vec{e}_n')$ following the relations:

$$\mathcal{B}:\vec{x}=\sum_{i=1}^{n}x_i\vec{e}_i \qquad \mathcal{B}':\vec{x}=\sum_{i=1}^{n}x_i'\vec{e}_i' \tag{6.6.130}$$

With:

$$\vec{X}=\begin{pmatrix}x_1\\x_2\\\ldots\\x_n\end{pmatrix},\vec{X}'=\begin{pmatrix}x_1'\\x_2'\\\ldots\\x_n'\end{pmatrix} \tag{6.6.131}$$

the vector of K^n formed of the components of $\vec{x}$ in the basis $\mathcal{B}$ and of the vector $\vec{x}$ formed of the components in the basis $\mathcal{B}'$. So:

$$X'=P^{-1}X \tag{6.6.132}$$

relation for which the detailed proof will be given later in our study of basis changes. We also have obviously:

$$X=PX' \tag{6.6.133}$$

Remarks

R1. When a vector is given and its basis is not specified, remember that it is therefore implicitly in the canonical basis:

$$(\vec{e}_1,\vec{e}_2,\ldots,\vec{e}_n)=\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix} \tag{6.6.134}$$

which remains invariant by the multiplication by any vector and when the basis used is denoted by $(\vec{e}_i)$ and is not specified, then it is also that of the canonical basis.

R2. If a vector is given relative to the canonical basis, its components are named "covariant", if they are expressed in another non-canonical base, then we say that the components are "contravariant" (for details on the subject see the section of Tensor Calculus).

D17. A matrix is named "positive-definite matrix" (which will be useful in the section of Numerical Methods for some important engineering techniques and in quantitative finance for qualitative estimation of the correlation matrix) if:

$$\forall \vec{x} \in \mathbb{R}^n: \quad \vec{x}^T A\vec{x} \geq 0 \land \vec{x}^T A\vec{x} = 0 \Longrightarrow \vec{x} = \vec{0} \tag{6.6.135}$$

or more simply if $\vec{x} \neq \vec{0}$:

$$\vec{x}^T A\vec{x} > 0 \tag{6.6.136}$$

and "semi-positive matrix" or "positive-semidefinite matrix" if:

$$\forall \vec{x} \in \mathbb{R}^n: \quad \vec{x}^T A\vec{x} \geq 0 \tag{6.6.137}$$

We have already proved that a semi-positive matrix has its eigenvalues which are all positive OR null, while if it is positive definite its eigenvalues are all positive AND not null (see section Analytical Geometry page 2794).

Notice that this implies that if a matrix A is invertible, then $B = A^T A$ is positive definite.

Indeed (even if we have already indirectly seen this proof in the section of Statistics at page 607), B is positive definite if for every non-zero $\vec{x}$ we have:

$$\vec{x}^T B\vec{x} > 0 \tag{6.6.138}$$

Now if we have A such that $B = A^T A$, then using the properties of transposed matrices:

$$\vec{x}^T B\vec{x} = \vec{x}^T (A^T A)\vec{x} = (A\vec{x})^T (A\vec{x}) = \|A\vec{x}\| \tag{6.6.139}$$

But:

$$\|A\vec{x}\| \geq 0 \tag{6.6.140}$$

If A in invertible, $\|A\vec{x}\| = 0$ only when $\vec{x} = 0$.

Let us prove also that the inverse of a positive definite matrix is also positive definite (important property for the Mahalonobis distance seen at page 2466 for example!).

First, let us recall that if A is positive definite, then we have proved (see section Statistics page 608) that it's determinant is never null and that therefore it's always invertible.

Secondly, we will prove further below at page 2004 during our study of spectral theorem that for a definite positive matrix M we have:

$$\det(M) = \prod_i \lambda_i \tag{6.6.141}$$

where λ_i are the eigenvalues of i (positive and non-null for definite positive matrices!). But also further below during our study of determinant at page 1970, we will prove for a matrix M that:

$$\det(M^{-1}) = \frac{1}{\det(M)} \tag{6.6.142}$$

Therefore:

$$\det(M^{-1}) = \frac{1}{\prod_i \lambda_i} = \prod_i \frac{1}{\lambda_i} \tag{6.6.143}$$

And as for a definite positive matrix we have all $\lambda_i > 0$, then M^{-1} is also positive definite since all $1/\lambda_i > 0$ and hence $\det(M^{-1})$ is also strictly positive.

We can extend the above definition so that in general a matrix M is said to be:

- "positive definite" if for any vector $\vec{x} \neq \vec{0}$, $\vec{x}^T M \vec{x} > 0$. This is sometimes denoted $M \succ \vec{0}$
- "positive semidefinite" if $\vec{x}^T M \vec{x} \geq 0$. This is sometimes denoted $M \succeq \vec{0}$
  - "non-negative definite" if it is either positive definite or positive semi definite[22]
- "negative definite" if for any vector $\vec{x} \neq \vec{0}$, $\vec{x}^T M \vec{x} < \vec{0}$. This is sometimes denoted $M \prec \vec{0}$
- "negative semidefinite" if $\vec{x}^T M \vec{x} \leq \vec{0}$. This is sometimes denoted $M \preceq \vec{0}$
  - "non-positive definite" if it is either negative definite or negative semi definite
- "indefinite" if it is nothing of those.

D18. The "adjugate", "classical adjoint", or "adjunct" of a square matrix is the transpose of its cofactor (see further below page 1971) matrix:

$$\text{adj}(A) = C^T = \left((-1)^{i+j} \det(A_{ij})\right)^T_{1 \leq i,j \leq n} \tag{6.6.144}$$

✍**Example:**

Consider a 3×3 matrix:

$$A = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} \tag{6.6.145}$$

Its cofactor matrix is:

$$C = \begin{pmatrix} +\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} & -\begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} & +\begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix} \\ -\begin{vmatrix} a_{12} & a_{13} \\ a_{32} & a_{33} \end{vmatrix} & +\begin{vmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{vmatrix} & -\begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix} \\ +\begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix} & -\begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix} & +\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} \end{pmatrix} \tag{6.6.146}$$

where:

$$\begin{vmatrix} a_{im} & a_{in} \\ a_{jm} & a_{jn} \end{vmatrix} = \det \begin{pmatrix} a_{im} & a_{in} \\ a_{jm} & a_{jn} \end{pmatrix} \tag{6.6.147}$$

---

[22] Non-negative definite and positive semidefinite are the same but as you can read the expression from time to time in some textbooks...

Its adjugate is the transpose of its cofactor matrix:

$$\text{adj}(A)=C^T=\begin{pmatrix} +\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} & -\begin{vmatrix} a_{12} & a_{13} \\ a_{32} & a_{33} \end{vmatrix} & +\begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix} \\ \\ -\begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} & +\begin{vmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{vmatrix} & -\begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix} \\ \\ +\begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix} & -\begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix} & +\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} \end{pmatrix} \tag{6.6.148}$$

D19. A symmetric square matrix having all it components being positive and only zeros on the diagonal is named a "distance matrix" or even sometimes a "pairwise similarity matrix" (we will meet several times this type of matrix in Data Mining techniques during our study of the Numerical Methods section). Most of times this matrix contains the distances, taken pairwise, between the elements of a set (indexed by the row and column number of the corresponding matrix). Depending upon the application involved, the distance being used to define this matrix may or may not be a metric.

A famous type of such matrix is the Euclidean distance matrix. If D_x^2 is a Euclidean distance matrix and the points $x_1,x_2,\ldots,x_n$ are defined on m-dimensional space, then the elements of A are given by:

$$D_x^2=[d_{ij}^2]=\|x_i-x_j\|_2^2 \tag{6.6.149}$$

where $\|\ldots\|_2$ denotes the 2-norm on $\mathbb{R}^m$ and:

$$D_x^2=\begin{bmatrix} 0 & d_{12}^2 & d_{13}^2 & \ldots & d_{1n}^2 \\ d_{21}^2 & 0 & d_{23}^2 & \ldots & d_{2n}^2 \\ d_{31}^2 & d_{32}^2 & 0 & \ldots & d_{3n}^2 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ d_{n1}^2 & d_{n2}^2 & d_{n3}^2 & \ldots & 0 \end{bmatrix} \tag{6.6.150}$$

D20. A matrix is named "sparse matrix" if it contains a significant number of null values. In numerical methods, there are algorithms that use this specificity to optimize the storage of this type of matrices (used in OLAP[23] cubes and financial engineering).

$$\begin{bmatrix} 11 & 22 & 0 & 0 & 0 & 0 & 0 \\ 0 & 33 & 44 & 0 & 0 & 0 & 0 \\ 0 & 0 & 55 & 66 & 77 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 88 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 99 \end{bmatrix} \tag{6.6.151}$$

The above sparse matrix contains only 9 non-zero elements, with 26 zero elements. Its sparsity is 74%, and its density is 26%.

D21. A "block matrix"(also named "partitioned matrix") is a matrix of the kind:

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} \tag{6.6.152}$$

---

[23] Acronym of OnLine Analytical Processing.

where A, B, C and D are matrices, named "blocks", such that:

- A and B have the same number of rows
- C and D have the same number of rows
- A and C have the same number of columns
- B and D have the same number of columns

Ideally, a block matrix is obtained by cutting a matrix two times: one vertically and one horizontally. Each of the four resulting pieces is a block.

✍**Examples:**

E1. The matrix:

$$\begin{bmatrix} 1 & 2 & 1 & 0 \\ 0 & 0 & 3 & 0 \\ 2 & 5 & 0 & 7 \\ 2 & 2 & 2 & 2 \end{bmatrix} \tag{6.6.153}$$

can be written as a block matrix:

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} \tag{6.6.154}$$

where:

$$\begin{aligned} A &= \begin{bmatrix} 1 & 2 \\ 0 & 0 \end{bmatrix} & B &= \begin{bmatrix} 1 & 0 \\ 3 & 0 \end{bmatrix} \\ C &= \begin{bmatrix} 2 & 5 \\ 2 & 2 \end{bmatrix} & D &= \begin{bmatrix} 0 & 7 \\ 2 & 2 \end{bmatrix} \end{aligned} \tag{6.6.155}$$

E2. The matrix:

$$\begin{bmatrix} 1 & 0 & 3 \\ 2 & 5 & 0 \\ 8 & 2 & 2 \end{bmatrix} \tag{6.6.156}$$

can be written as a block matrix:

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} \tag{6.6.157}$$

where:

$$\begin{aligned} A &= \begin{bmatrix} 1 \end{bmatrix} & B &= \begin{bmatrix} 0 & 3 \end{bmatrix} \\ C &= \begin{bmatrix} 2 \\ 8 \end{bmatrix} & D &= \begin{bmatrix} 5 & 0 \\ 2 & 2 \end{bmatrix} \end{aligned} \tag{6.6.158}$$

An important fact about block matrices is that their multiplication can be carried out as if their blocks were scalars, by using the standard rule for matrix multiplication:

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix}\begin{bmatrix} E & F \\ G & H \end{bmatrix}=\begin{bmatrix} AE+BG & AF+BH \\ CE+DG & CF+DH \end{bmatrix} \tag{6.6.159}$$

The only caveat is that all the blocks involved in a multiplication (e.g., AE, BG, CE) must be conformable. For example, the number of columns of A and the number of rows of E must coincide.

Many proofs in linear algebra are greatly simplified if one can easily deal with the determinants of block matrices, that is, matrices that are subdivided into blocks that are themselves matrices.

Finally, to close this enumeration of types of matrices, remember that we saw the "correlation matrix" on page 621, the "quasi-correlation matrix" on page 607 and also the Fisher information matrix at page 839.

6.6.3.4 Determinant

We will look at determinants in the point of view of the physicist or of the engineer (the mathematician point of view is rather off-putting ...). In physics (whether in classical mechanics and quantum field physics), chemistry or engineering, we frequently have to solve linear systems. But we have now seen that a linear system:

$$\begin{aligned} a_{11}x_1+a_{12}x_2+\ldots+a_{1n}x_n&=b_1\\ a_{21}x_1+a_{22}x_2+\ldots+a_{2n}x_n&=b_2\\ &\ldots\\ a_{m1}x_1+a_{m2}x_2+\ldots+a_{mn}x_n&=b_m \end{aligned} \tag{6.6.160}$$

can be written as:

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix}\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}=\begin{pmatrix} b_1 \\ b_2 \\ \vdots \\ b_n \end{pmatrix} \Leftrightarrow AX=B \tag{6.6.161}$$

and we know that the only soluble linear systems (in the sense that they have a unique solution !!!) are those that have as many equations as unknowns and their determinant is not zero! Thus, the matrix A must be a square matrix M_{mm}.

If a solution exists, then there is a column matrix (or "vector") X such that $AX=B$ which involves:

$$X=A^{-1}B \tag{6.6.162}$$

What imposed this relation? Well this is relatively simple, but at the same time very important: for a linear system to have a unique solution, it is necessary that the matrix is invertible (non-singular)! What relation with the concept of "determinant" then? It's simple: mathematicians have sought how to write inverse matrices of linear systems for which they knew there was a unique solution and they arrived after trial and error to determine a kind of formula to assess if the matrix is invertible (non-singular) or not. Once this formula found, they formalized (as they know so well how to do it...), with a great rigour, the concept surrounding this formula that they named the "determinant". They did it so well that in fact we sometimes forgot that they have found it by trial and error...

Remark

If a matrix of a linear system is not invertible (non-singular), this has the consequence that there is no solution or an infinity of solutions (as usual what ...)

We below first focus on how to build the determinant by defining a particular type of application. Then, after seeing a simple and readable example of the calculation of a determinant, we will focus on determining the formula of it in the general case. Finally, once this is done, we will see what is the relation between the inverse of a matrix and the determinant!!!

In what will follow all vector spaces will be considered of finite dimension and the field of complex numbers $\mathbb{C}$ (those who prefer the can take $\mathbb{R}$ as basis field, in fact we could take any field).

First of all we will do a little bit of pure math (a bit off putting) before moving on concrete stuff.

Given V a vector space, we will write as usual V^n instead of $V\times V\times\ldots\times V$. $(\vec{e}_1,\vec{e}_2,\ldots,\vec{e}_3)$ designate the canonical basis of $\mathbb{R}^n$. $M_n(\mathbb{R})$ is the set of square matrices $n\times n$ with coefficients in $\mathbb{R}$.

Definitions (#6.6.257):

D1. A "multi-linear application" on a space V is defined by an $\varphi:V^n\rightarrow\mathbb{R}$ which is linear in each of its components. Meaning:

$$\begin{aligned}&\varphi(\vec{x}_1,\ldots,\vec{x}_{j-1},\lambda\vec{u}+\mu\vec{v},\vec{x}_{j+1},\ldots,\vec{x}_n)\\&=\lambda\varphi(\vec{x}_1,\ldots,\vec{x}_{j-1},\vec{u},\vec{x}_{j+1},\ldots,\vec{x}_n)+\mu\varphi(\vec{x}_1,\ldots,\vec{x}_{j-1},\vec{v},\vec{x}_{j+1},\ldots,\vec{x}_n)\end{aligned}\tag{6.6.163}$$

for any $\lambda,\mu\in\mathbb{K}$ and $\vec{x}_i,\vec{u},\vec{v}\in V$ where the $\vec{x}_i$ are vectors.

Remark

A non-null multi-linear application is not a linear application of the space V^n in $\mathbb{R}^n$. Excepted if $n=1$. Indeed, this can be verified by the definition of a linear application versus the one of the multi-linear application:

$$\lambda\varphi(\vec{x}_1,\vec{x}_2,\ldots,\vec{x}_n)\neq\varphi(\lambda\vec{x}_1,\lambda\vec{x}_2,\ldots,\lambda\vec{x}_n)\tag{6.6.164}$$

$$\varphi(\vec{x}_1,\vec{x}_2,\ldots,\vec{x}_n)+\varphi(\vec{x}_1,\vec{x}_2,\ldots,\vec{x}_n)\neq\varphi(2\vec{x}_1,2\vec{x}_2,\ldots,2\vec{x}_n)\tag{6.6.165}$$

D2. An "alternated multi-linear application" on V is by definition a multi-linear application that satisfies:

$$\varphi(\vec{x}_1,\ldots,\vec{x}_j,\vec{x}_{j+1},\vec{x}_{j+2},\ldots,\vec{x}_n)=-\varphi(\vec{x}_1,\ldots,\vec{x}_{j+1},\vec{x}_j,\vec{x}_{j+2},\ldots,\vec{x}_n)\tag{6.6.166}$$

for any $j=1\ldots n, \vec{x}_j \in V$. Therefore the permutation of two vectors that follows change the sign of φ.

Theorem 6.39. Therefore, if φ is a multi-linear application, then φ is alternated if and only if $\forall \vec{j} \in V, j=1\ldots n$ we have:

$$\varphi(\vec{x}_1,\ldots,\vec{x}_j,\vec{x}_j,\vec{x}_{j+2},\ldots,\vec{x}_n)=0 \tag{6.6.167}$$

or in a more simple case:

$$\varphi(\vec{x}_j,\vec{x}_j)=0 \tag{6.6.168}$$

Proof 6.39.1. If φ is alternated we have by definition:

$$\varphi(\vec{x}_1,\ldots,\vec{x}_j,\vec{x}_{j+1},\vec{x}_{j+2},\ldots,\vec{x}_n)=-\varphi(\vec{x}_1,\ldots,\vec{x}_{j+1},\vec{x}_j,\vec{x}_{j+2},\ldots,\vec{x}_n) \tag{6.6.169}$$

Therefore by rearranging:

$$\varphi(\vec{x}_1,\ldots,\vec{x}_j,\vec{x}_{j+1},\vec{x}_{j+2},\ldots,\vec{x}_n)+\varphi(\vec{x}_1,\ldots,\vec{x}_{j+1},\vec{x}_j,\vec{x}_{j+2},\ldots,\vec{x}_n)=0 \tag{6.6.170}$$

And if φ is a multi-linear application we can write:

$$2\varphi(\vec{x}_1,\ldots,\vec{x}_j,\vec{x}_{j+1},\vec{x}_{j+2},\ldots,\vec{x}_n)=0 \tag{6.6.171}$$

■ Q.E.D.

Now comes the interesting stuff:

D3. A "determinant" is by definition a multi-linear alternated application:

$$D:\underbrace{\mathbb{R}^n\times\ldots\times\mathbb{R}^n}_{n\text{ times}}\mapsto\mathbb{R} \tag{6.6.172}$$

satisfying as well:

$$D(\vec{e}_1,\ldots,\vec{e}_n)=\det(\vec{e}_1,\ldots,\vec{e}_n)=1 \tag{6.6.173}$$

Remark

The columns of a matrix form n vectors and we then see that a determinant D on $\mathbb{R}^n$ induce an application D of $M_n(\mathbb{R})\mapsto\mathbb{R}$ (where as we know $M_n(\mathbb{R})$ is the set of square matrices $n\times n$ with components in $\mathbb{R}$) defined by:

$$D(M)=D(\vec{m}_1,\vec{m}_2,\ldots,\vec{m}_n) \tag{6.6.174}$$

where $\vec{m}_i$ is the i-th column of M.

Let us study the case $n=2$. If D is a determinant, for any vector:

$$\vec{x}=\lambda\vec{e}_1+\mu\vec{e}_2 \qquad \vec{y}=\alpha\vec{e}_1+\beta\vec{e}_2 \tag{6.6.175}$$

we have:

$$D(\vec{x},\vec{y})=D(\lambda\vec{e}_1+\mu\vec{e}_2,\alpha\vec{e}_1+\beta\vec{e}_2) \tag{6.6.176}$$

As D is multi-linear, we have:

$$\begin{aligned}D(\vec{x},\vec{y})&=D(\lambda\vec{e}_1+\mu\vec{e}_2,\alpha\vec{e}_1+\beta\vec{e}_2)=\lambda D(\vec{e}_1,\alpha\vec{e}_1+\beta\vec{e}_2)+\mu D(\vec{e}_2,\alpha\vec{e}_1+\beta\vec{e}_2)\\&=\lambda(\alpha D(\vec{e}_1,\vec{e}_1)+\beta D(\vec{e}_1,\vec{e}_2))+\mu(\alpha D(\vec{e}_2,\vec{e}_1)+\beta D(\vec{e}_2,\vec{e}_2))\\&=\lambda\alpha D(\vec{e}_1,\vec{e}_1)+\lambda\beta D(\vec{e}_1,\vec{e}_2)+\mu\alpha D(\vec{e}_2,\vec{e}_1)+\mu\beta D(\vec{e}_2,\vec{e}_2)\end{aligned}\tag{6.6.177}$$

as it is alternated:

$$D(\vec{e}_1,\vec{e}_1)=0 \qquad D(\vec{e}_2,\vec{e}_2)=0\tag{6.6.178}$$

it remains:

$$D(\lambda\vec{e}_1+\mu\vec{e}_2,\alpha\vec{e}_1+\beta\vec{e}_2)=\lambda\beta D(\vec{e}_1,\vec{e}_2)+\mu\alpha D(\vec{e}_2,\vec{e}_1)\tag{6.6.179}$$

and we have:

$$D(\lambda\vec{e}_1+\mu\vec{e}_2,\alpha\vec{e}_1+\beta\vec{e}_2)=\lambda\beta D(\vec{e}_1,\vec{e}_2)-\mu\alpha D(\vec{e}_1,\vec{e}_2)\tag{6.6.180}$$

And finally:

$$D(\lambda\vec{e}_1+\mu\vec{e}_2,\alpha\vec{e}_1+\beta\vec{e}_2)=\lambda\beta-\mu\alpha\tag{6.6.181}$$

In fact, we just proved that if the a determinant exists, it is unique and of the form indicated previously, we should also check that the defined application satisfy the properties of a determinant, but the latter is immediate.

Thus, if:

$$M=\begin{bmatrix}a_{11} & a_{12}\\ a_{21} & a_{22}\end{bmatrix}\tag{6.6.182}$$

is a matrix we have then (notice the three common notations for the determinant that you can find in various textbooks and even in the actual one depending on the context and of the traditions):

$$D(M)=\det(M)=|M|=a_{11}a_{22}-a_{21}a_{12}\tag{6.6.183}$$

Let us give now a geometric interpretation of the determinant. Given $\vec{v}_1,\vec{v}_2$ two vectors of $\mathbb{R}^2$:

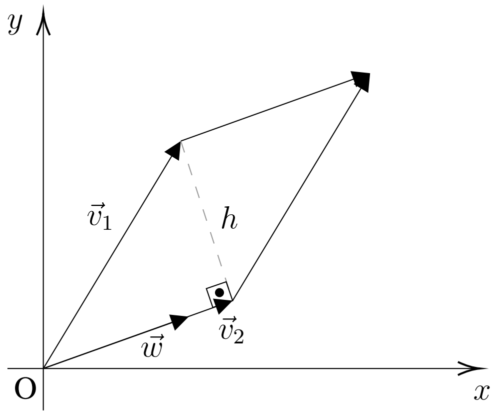


Figure 6.144: Geometrical interpretation of the determinant

The vector $\vec{w}$ is obtained by projecting $\vec{v}_1$ on $\vec{v}_2$ and we have therefore:

$$\vec{w} = \frac{\vec{v}_1 \circ \vec{v}_2}{\|\vec{v}_2\|^2}\vec{v}_2 \text{ and } \|\vec{h}_2\|^2 = \|\vec{v}_1\|^2 - \|\vec{v}_2\|^2 = \|\vec{v}_1\|^2 - \frac{(\vec{v}_1 \circ \vec{v}_2)^2}{\|\vec{v}_2\|^4}\|\vec{v}_2\|^2 = \|\vec{v}_1\|^2 - \frac{(\vec{v}_1 \circ \vec{v}_2)^2}{\|\vec{v}_2\|^2} \tag{6.6.184}$$

The area of the above parallelogram is therefore:

$$S = \|\vec{v}_2\| \cdot \|\vec{h}\| = \|\vec{v}_2\| \left(\|\vec{v}_1\|^2 - \frac{(\vec{v}_1 \circ \vec{v}_2)^2}{\|\vec{v}_2\|^2}\right)^{1/2} = \left(\|\vec{v}_1\|^2\|\vec{v}_2\|^2 - (\vec{v}_1 \circ \vec{v}_2)^2\right)^{1/2} \tag{6.6.185}$$

if:

$$\vec{v}_1 = \lambda\vec{e}_1 + \mu\vec{e}_2 \quad \text{and} \quad \vec{v}_2 = \alpha\vec{e}_1 + \beta\vec{e}_2 \tag{6.6.186}$$

then:

$$S^2 = \left(\lambda^2 + \mu^2\right)\left(\alpha^2 + \beta^2\right) = \lambda^2\beta^2 + \mu^2\alpha^2 - 2\lambda\alpha\mu\beta = (\lambda\beta - \mu\alpha)^2 \tag{6.6.187}$$

and finally:

$$S = |\lambda\beta - \mu\alpha| = |D(\vec{v}_1, \vec{v}_2)| = \left|\det\left(\begin{bmatrix}\lambda & \alpha \\ \mu & \beta\end{bmatrix}\right)\right| \tag{6.6.188}$$

Therefore the determinant, in absolute value, represents the area of the parallelogram defined by the vectors $\vec{v}_1, \vec{v}_2$ when these vectors are linearly independent. We can generalize this result to a n-dimensional space, in particular, for $n = 3$, the determinant of three linearly independent vectors represents the volume of the parallelepiped defined by these as we already proved it during our study of the mixed product in the section of Vector Calculus page 1838.

The more general case of the expression of the determinant is a little trickier to ascertain. This requires that we define a particular bijective application but simple that we have already met in the section Statistics.

Definition (#6.6.258): Given $F_n = \{1, 2, \ldots, n\}, n \in \mathbb{N}^*$ we name "permutation" of F_n any bijective application of F_n in F_n:

$$\sigma : \{1, 2, \ldots, n\} \rightarrow \{1, 2, \ldots, n\} \tag{6.6.189}$$

Given $\mathcal{S}_n$ the set of possible permutations (bijective applications) of $\{1, 2, \ldots, n\}$. $\mathcal{S}_n$ obviously contains ... (see our study of Combinatorics in the section of Probabilities) $n!$ elements. The information an element σ of $\mathcal{S}_n$ is defined by the successive information of:

$$\sigma(1)\ (\sigma(1) \in F_n) \tag{6.6.190}$$

$$\sigma(2)\ (\sigma(2) \in F_n - \{\sigma(1)\}) \tag{6.6.191}$$

$$\ldots\sigma(n)\ (\sigma(n) \in F_n - \{\sigma(1), \sigma(2), \ldots, \sigma(n-1)\}) \tag{6.6.192}$$

Given an ordered sequence of elements (ascending) $\{1, 2, \ldots, n\}, n \in \mathbb{N}^*$ we name "inversion", any permutation of elements in the ordered sequence (so the result will not be ordered at all...). We denote by $I(\sigma)$ the number of inversions.

We say that the permutation σ is even (odd) if $I(\sigma)$ is even (odd). We name "signature" of σ, the number $\varepsilon(\sigma)$ defined by $\varepsilon(\sigma)=(-1)^{I(\sigma)}$, that is to say:

$$\varepsilon(\sigma)=\begin{cases}+1 & \text{if the permutation } \sigma \text{ is even}\\ -1 & \text{if the permutation } \sigma \text{ is odd}\end{cases}\tag{6.6.193}$$

We now have the necessary tools to set up the general relation of the determinant!

Definition (#6.6.259): Given:

$$A=(a_{ij})_{1\leq i,j\leq n}\in M_{nn}(\mathbb{K})\tag{6.6.194}$$

We name "determinant of a square matrix A" of dimension n, and we denote by $\det(A)$ (or sometimes by $D(A)$ or especially in the field of Statistics by $|A|$), the scalar defined by (we'll see a few examples further below):

$$\boxed{\det(A)=\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)a_{1\sigma(1)}a_{2\sigma(2)}\ldots a_{n\sigma(n)}=\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)\prod_{i=1}^{n}a_{i\sigma(i)}}\tag{6.6.195}$$

sometimes named "Leibniz formula of determinants" or "Laplace's formula". This relation seems to have been obtained in the past by trial and error and by induction for larger dimensions.

✍**Examples:**

E1. Given $A=(a_{ij})_{1\leq i,j\leq 2}\in M_{22}(\mathbb{K})$, let us consider the $2!=2$ permutations of the second indices (of integers $1,2$) taken in their whole:

$$12 \qquad 21$$

We calculate the signature of σ. Here is the scheme of this rule (recall: we say that there is an "inversion", if in a permutation, a greater integer precede a smallest integer):

$\sigma(1)\sigma(2)$	$\underbrace{12}_{\sigma(1)\sigma(2)}$	$\underbrace{21}_{\sigma(1)\sigma(2)}$
Number of inversions	0	1
Permutation	even	odd
$\varepsilon(\sigma)=(-1)^{I(\sigma)}$	$+1$	-1

Table 6.18: **Inversions and permutations of a determinant of order 2**

Therefore we have:

$$\begin{aligned}\det\begin{bmatrix}a_{11} & a_{12}\\ a_{21} & a_{22}\end{bmatrix}&=\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)a_{1\sigma(1)}a_{2\sigma(2)}\\ &=\underbrace{a_{11}a_{22}}_{\varepsilon(\sigma)=+1\begin{cases}\sigma(1)=1\\ \sigma(2)=2\end{cases}}-\underbrace{a_{12}a_{21}}_{\varepsilon(\sigma)=-1\begin{cases}\sigma(1)=2\\ \sigma(2)=1\end{cases}}\end{aligned}\tag{6.6.196}$$

This corresponds well to what we saw initially. Remember also on the way that we will soon prove that the determinant of a square matrix must be zero so that the matrix is invertible (non-singular)!

E2. Given $A=(a_{ij})_{1\leq i,j\leq 3}\in M_{33}(\mathbb{K})$, let us consider the $3!=6$ permutations of the second indices (integers $1,2,3$) taken in their whole:

$$123 \quad 132 \quad 213 \quad 31 \quad 312 \quad 321$$

We calculate the signatures of σ. Here is a scheme of this rule (recall: we say that there is an "inverse", if in a permutation, a greatest integer precedes a lower integer):

$\sigma(1)\sigma(2)$	123	132	213	231	312	321
Number of inversions	0	1	1	2	2	3
Permutation	even	odd	odd	even	even	odd
$\varepsilon(\sigma)=(-1)^{I(\sigma)}$	$+1$	-1	-1	$+1$	$+1$	-1

Table 6.19: **Inversions and permutations of a determinant of order** 3

Therefore we have:

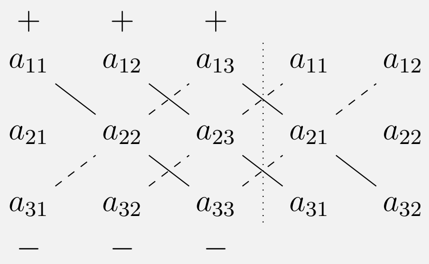
$$\begin{aligned}\det\begin{bmatrix}a_{11} & a_{12} & a_{13}\\ a_{21} & a_{22} & a_{23}\\ a_{31} & a_{32} & a_{33}\end{bmatrix} &= \sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)a_{1\sigma(1)}a_{2\sigma(2)}a_{3\sigma(3)}\\ &=a_{11}\det\begin{pmatrix}a_{22} & a_{23}\\ a_{32} & a_{33}\end{pmatrix}-a_{12}\det\begin{pmatrix}a_{21} & a_{23}\\ a_{31} & a_{33}\end{pmatrix}+a_{13}\det\begin{pmatrix}a_{21} & a_{22}\\ a_{31} & a_{32}\end{pmatrix}\\ &=a_{11}a_{22}a_{33}-a_{11}a_{23}a_{32}-a_{12}a_{21}a_{33}+a_{12}a_{23}a_{31}+a_{13}a_{21}a_{32}-a_{13}a_{22}a_{31}\end{aligned}\tag{6.6.197}$$

From the above formula, each term is in the form of $a_{1j_1}a_{2j_2}a_{3j_3}$ where the second indices j_1,j_2,j_3 is a permutation of $1,2,3$. For example, the first term has $1,2,3$ as the second indices; the second term has $1,3,2$; the third term has $2,1,3$, etc.

The sign of each term is the sign of the permutation. For example, the sign of $1,2,3$ is clearly 1. For the second term, $1,3,2$ is obtained from $1,2,3$ by one transposition $2,3\rightarrow 3,2$, so the sign is -1, etc.

Remark

Some people learn by heart a method named "rule of Sarrus" to calculate the determinants of order three as the previous one given by:



+ + +
a_{11} a_{12} a_{13} a_{11} a_{12}
a_{21} a_{22} a_{23} a_{21} a_{22}
a_{31} a_{32} a_{33} a_{31} a_{32}
− − −

We prefer in this textbook the general formulation of the determinant because applicable to all orders.

Let us see some properties and corollaries of this formulation of the determinant:

P1. Given a square matrix $M_n(K)$ of order n, we do not change the value of the determinant of M_n:

  (a) By performing an elementary operation on the columns of M_n.
  (b) By performing an elementary operation on the rows of M_n.

Proof 6.39.2. If $M_n=(a_{ij})_{i,j=1\dots n}$ then M_n is composed of n column vectors:

$$\vec{v}_n=\begin{pmatrix} a_{1j}\\ a_{2j}\\ \vdots \\ a_{nj}\end{pmatrix} \tag{6.6.198}$$

Doing an elementary operation on the columns of M_n is equivalent to add $\lambda v_i, i\in\{1,\dots,n\}$ to one of the columns v_n of M_n. Given M_n' the matrix obtained by adding λv to the j-th column of M_n, we get:

$$\det(M_n')=\det(v_1,\dots,v_i,\dots,v_j+\lambda v_i,\dots,v_n) \tag{6.6.199}$$

By multi-linearity (finally the proof in not really difficult):

$$\det(M')=\det(v_1,\dots,v_i,\dots,v_j,\dots,v_n)+\lambda\det(v_1,\dots,v_i,\dots,v_i,\dots,v_n) \tag{6.6.200}$$

and as the determinant is alternated:

$$\lambda\det(v_1,\dots,v_i,\dots,v_i,\dots,v_n)=0\Leftarrow\det(M_n')=\det(v_1,\dots,v_i,\dots,v_j,\dots,v_n)=\det(M_n) \tag{6.6.201}$$

About the elementary operations on the rows we just need to consider the transpose (that is to cry such it is simple, but we had to thing about this trick).

■ Q.E.D.

P2. Given $M_n(\mathbb{K})$ a square matrix of order n and given $\lambda\in\mathbb{K}$:

$$\boxed{\det(\lambda M_n)=\lambda^n\det(M_n)} \tag{6.6.202}$$

Proof 6.39.3. As before, it is enough to simply noticed that if $v_1,\dots,v_n$ are the column vectors forming the matrix M_n then $\lambda v_1,\dots,\lambda v_n$ are those that constitute λM_n and:

$$\det(\lambda M_n)=\det(\lambda v_1,\dots,\lambda v_n) \tag{6.6.203}$$

The application being n-linear, we arrive at the equality:

$$\det(\lambda M_n)=\lambda^n\det(v_1,\dots,v_n)=\lambda^n\det(M_n) \tag{6.6.204}$$

■ Q.E.D.

P3. Given $M_n(\mathbb{K})$ a square matrix of order n. We change the sign of the determinant of M_n if:

- We permute two of its columns
- We permute two of its rows

Proof 6.39.4. M_n is constituted by n vectors $v_1,..,v_n$. The determinant of M_n is equal to the determinant of these n. Permute two columns of M_n is same as permuting the two corresponding vectors. Let us suppose that the permuted vectors are the i-th and j-th, the determinant being an alternate application, we have:

$$\det(v_1,\ldots,v_i,\ldots,v_j,\ldots,v_n)=-\det(v_1,\ldots,v_j,\ldots,v_i,\ldots,v_n) \tag{6.6.205}$$

About the rows, we just have to consider the transposed of M_n to arrive to the same result!

■ Q.E.D.

P4. Given $A,B\in M_n\in(\mathbb{C})$ then:

$$\boxed{\det(A\cdot B)=\det(A)\cdot\det(B)} \tag{6.6.206}$$

As far as we know the proof can be done in at least two ways, the first is rather indigestible and abstract... so we will let it to mathematicians (...) even if it has the advantage of being general, the second one (much more easier) is to check this assertion for various squared matrices (the way engineers would do it...):

Proof 6.39.5.

$$\begin{aligned}\det(A\cdot B)=\det\left(\begin{bmatrix}a_{11} & a_{22}\\ a_{21} & a_{22}\end{bmatrix}\begin{bmatrix}b_{11} & b_{22}\\ b_{21} & b_{22}\end{bmatrix}\right)&=\det\left(\begin{bmatrix}a_{11}b_{11}+a_{12}b_{21} & a_{11}b_{12}+a_{12}b_{22}\\ a_{21}b_{11}+a_{22}b_{11} & a_{21}b_{12}+a_{22}b_{22}\end{bmatrix}\right)\\ &=(a_{11}b_{11}+a_{12}b_{21})(a_{21}b_{11}+a_{22}b_{11})-(a_{11}b_{12}+a_{12}b_{22})(a_{21}b_{11}+a_{22}b_{11})\\ &=\cancel{a_{11}b_{11}a_{21}b_{12}}+a_{11}b_{11}a_{22}b_{22}+a_{12}b_{21}a_{21}b_{12}+\cancel{a_{12}b_{21}a_{22}b_{22}}\\ &-\cancel{a_{11}b_{12}a_{21}b_{11}}-a_{11}b_{12}a_{22}b_{21}-a_{12}b_{22}a_{21}b_{11}-\cancel{a_{12}b_{22}a_{22}b_{21}}\\ &=a_{11}b_{11}a_{22}b_{22}-a_{11}b_{12}a_{22}b_{21}-a_{12}b_{22}a_{21}b_{11}+a_{12}b_{21}a_{21}b_{12}\\ &=a_{11}a_{22}b_{11}b_{22}-a_{11}a_{22}b_{12}b_{21}-a_{12}a_{21}b_{22}b_{11}+a_{12}a_{21}b_{21}b_{12}\end{aligned} \tag{6.6.207}$$

and:

$$\begin{aligned}\det(A)\det(B)&=(a_{11}a_{22}-a_{12}a_{21})(b_{11}b_{22}-b_{12}b_{21})\\ &=a_{11}a_{22}b_{11}b_{22}-a_{11}a_{22}b_{12}b_{21}-a_{12}a_{21}b_{22}b_{11}+a_{12}a_{21}b_{21}b_{12}\end{aligned} \tag{6.6.208}$$

The calculations therefore produce results that are identical. We can check for square matrices of higher dimensions.

■ Q.E.D.

P5. A square matrix $A\in M_n(\mathbb{C})$ is invertible (non-singular) if and only if $\det(A)\neq 0$ (this is the most important property among all).

Proof 6.39.6. If A is invertible (non-singular), we have:

$$\boxed{\det\left(A\cdot A^{-1}\right)=\det(\mathbb{1})=\det(A)\det\left(A^{-1}\right)\Rightarrow\det(A)\neq 0} \tag{6.6.209}$$

■ Q.E.D.

Notice that as $\det(\mathbb{1})=1$, if follow immediately that :

$$\det(A^{-1})=\frac{1}{\det(A)} \tag{6.6.210}$$

As we already said it, this is the most important property of matrices as part of theoretical physics because if A is a linear system, the calculation of the determinant indicates whether it has unique solutions or not. Otherwise, as we have already mentioned and study it, the system has no solution, or an infinity of solutions!

We must consider an important special case! Given the following system:

$$A\cdot B=0\Longrightarrow B=0 \tag{6.6.211}$$

where $A\in M_n(\mathbb{K})\neq 0$ and $B\in M_n(\mathbb{K})\neq 0$ are to be determined. It is obvious that A is invertible (non-singular) or not, the trivial solution is $A\cdot B=0$. However, let us imagine a case of theoretical physics where we have $A\cdot B=0$ but for which we know that $A\in M_n(\mathbb{K})\neq 0$ for which we impose $B\in M_n(\mathbb{K})\neq 0$. In this case, we must eliminate the trivial solution $B=0$. Furthermore, calculate the inverse (if it exists) of the matrix A will bring us to nothing concrete except that $B=0$ which obviously does not satisfy us. The only solution is then to play such that the coefficients a_{ij} of the matrix A are such that its determinant is zero and therefore the matrix in invertible! The advantage? Just to have an infinite number of possible solutions (of B then!) that satisfy $A\cdot B=0$. We will need this methodology in the section of Wave Quantum Physics, when we will determine the existence of antiparticles through the linearised Dirac equation. It must therefore be remember.

P6. Two "conjugated" matrices (be careful! it is not the "conjugate" in the complex sense) have the same determinant.

Proof 6.39.7. Let $A\in M_n(\mathbb{C})$, and $P\in M_n(\mathbb{C})$ be a transition matrix from one base to another (see further our study of base changes), then we have:

$$\det(B)=\det\left(P^{-1}AP\right)=\underbrace{\det(P^{-1})}_{=(\det(P))^{-1}}\det(A)\det(P)=\det(A) \tag{6.6.212}$$

$$\det(\overline{A})=\overline{\det(A)} \tag{6.6.213}$$

■ Q.E.D.

P7. For any matrix $A\in M_n(\mathbb{C})$:

Proof 6.39.8.

$$\det(\overline{A})=\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)\cdot\overline{a_{1,\sigma(1)}}\cdot\ldots\cdot\overline{a_{n,\sigma(n)}} \tag{6.6.214}$$

But as (trivial... simple product of all coefficients):

$$\overline{a_{1,\sigma(1)}}\cdot\ldots\cdot\overline{a_{n,\sigma(n)}}=\overline{a_{\sigma-1(1),1}}\cdot\ldots\cdot\overline{a_{\sigma-1(n),n}} \tag{6.6.215}$$

As (trivial) $\varepsilon(\sigma^-1)=\varepsilon(\sigma)$ and that $x,y\in\mathbb{C}:\bar{x}\cdot\bar{y}=\overline{x\cdot y}$ (see section Numbers page 247) then we can write:

$$\begin{aligned}\det(\bar{A})&=\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)\cdot\overline{a_{\sigma^{-1}(1),1}}\cdot\ldots\cdot\overline{a_{\sigma^{-1}(n),n}}=\overline{\sum_{\sigma^{-1}\in\mathcal{S}_n}\varepsilon(\sigma^{-1})\cdot a_{\sigma^{-1}(1),1}\cdot\ldots\cdot a_{\sigma^{-1}(n),n}}\\&=\overline{\det(A)}\end{aligned} \tag{6.6.216}$$

■ Q.E.D.

P8. For any matrix $A\in M_n(\mathbb{R})$:

$$\det(A^T)=\det(A) \tag{6.6.217}$$

Proof 6.39.9. Well... it's the same as the previous property but without the conjugate values... In fact, we prove in the same way, the same property for $A\in M_n(\mathbb{C})$.

■ Q.E.D.

P9. Given a matrix $A=(a_{ij})\in M_n(\mathbb{C})$ we denote by A_{ij} the matrix obtained from A by removing the i-th row and the j-th column (very important notation to remember for what will follow!!!). The A_{ij} belongs therefore to $M_{n-1}(\mathbb{C})$. Then for any $i=1\ldots n$:

$$\boxed{\det(A)=\sum_{j=1}^{n}(-1)^{i+j}\cdot a_{ij}\cdot\det(A_{ij})} \tag{6.6.218}$$

where the term:

$$C_{ij}=(-1)^{i+j}\cdot\det(A_{ij}) \tag{6.6.219}$$

is named the "cofactor[24]" or "partial determinant", $\det(A_{ij})$ is named the "minor", and the whole boxed relation above is named the "cofactor expansion theorem".

Proof 6.39.10. For the proof let us define the application:

$$\varphi:M_n(\mathbb{C})\mapsto\mathbb{C},\varphi(A):=\sum_{j=1}^{n}(-1)^{i+j}a_{ij}\det(A_{ij}) \tag{6.6.220}$$

It could be almost easy to see that φ is multi-linear (you just have to consider that $(-1)^{i+j}a_{ij}$ as a simple constant and after by extension of the definition of the determinant... too easy...).

---

[24] From all the cofactors we can build a "cofactor matrix" containing all C_{ij}.

Let us show however that this application is alternated (in this case it is a determinant hat has all the properties of a... determinant!).

Given a_k, a_{k+1} two column vectors A that follows each other. Let us suppose that $a_k = a_{k+1}$, we have to show in this case that $\varphi(A) = 0$ (which comes from the definition of an alternate application).

We have first (it is mandatory by the definition itself) if we don't erase any of the columns j being k or $k+1$:

$$\det(A_{ij}) = 0 \quad \text{if } j \neq k, k+1 \tag{6.6.221}$$

and we have obviously if we remove respectively the column k and the column $k+1$:

$$\det(A_{ik}) = \det(A_{i(k+1)}) \quad \text{and} \quad A_{i,k} = A_{i,k+1} \tag{6.6.222}$$

Therefore:

$$\varphi(A) = (-1)^{i+k} a_{ik} \det(A_{ik}) + (-1)^{i+(k+1)} a_{i(k+1)} \det(A_{i(k+1)}) = 0 \tag{6.6.223}$$

It is therefore OK. The application φ is alternated and multi-linear, it is indeed well a determinant!

We have just proved that φ is a determinant and by unicity we have $\varphi(A) = \det(A)$ for any $A \in M_n(\mathbb{C})$.

■ Q.E.D.

Remark

So finally we have seen now in details the concepts of cofactor that should permit the reader to understand the concept of "adjugate matrix" (or "comatrix") that we had introduce at the beginning of this section at the page 1958.

If we take the following 2×2 matrix:

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \tag{6.6.224}$$

we get:

$$\text{adj}(A) = C^T = \left((-1)^{i+j} \det(A_{ij})\right)^T_{1 \leq i,j \leq n} = \text{adj}(A) = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \tag{6.6.225}$$

Or if we take the following 3×3 matrix (already used in an example earlier!):

$$A = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} \tag{6.6.226}$$

Then the cofactor matrix is given by:

$$C = \begin{pmatrix} +\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} & -\begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} & +\begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix} \\ \\ -\begin{vmatrix} a_{12} & a_{13} \\ a_{32} & a_{33} \end{vmatrix} & +\begin{vmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{vmatrix} & -\begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix} \\ \\ +\begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix} & -\begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix} & +\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} \end{pmatrix} \tag{6.6.227}$$

And we notice something that can be generalized: if A is symmetric, then $C=C^T$.

✍**Example:**

Let us see an example of this method by calculating the determinant of:

$$A=\begin{pmatrix}1 & 2 & 3\\ 2 & 1 & 0\\ 1 & -1 & \mathrm{i}\end{pmatrix}\tag{6.6.228}$$

Let us develop the second line ($i=2$). We get:

$$\begin{aligned}\det(A)&=\begin{bmatrix}1 & 2 & 3\\ 2 & 1 & 0\\ 1 & -1 & \mathrm{i}\end{bmatrix}\\ &=\sum_{j=1}^{n}(-1)^{i+j}\cdot a_{ij}\cdot\det(A_{ij})=\sum_{j=1}^{3}(-1)^{2+j}\cdot a_{2j}\cdot\det(A_{2j})\\ &=(-1)^3\cdot 2\cdot\det\begin{pmatrix}2 & 3\\ -1 & \mathrm{i}\end{pmatrix}+(-1)^4\cdot 1\cdot\det\begin{pmatrix}1 & 3\\ 1 & \mathrm{i}\end{pmatrix}+(-1)^5\cdot 0\cdot\det\begin{pmatrix}1 & 2\\ 1 & -1\end{pmatrix}\\ &=-2\cdot(2\mathrm{i}+3)+\mathrm{i}-3=-3\mathrm{i}-9\end{aligned}\tag{6.6.229}$$

Let us develop following the first column for verification (we never know...):

$$\begin{aligned}\det(A)=\begin{bmatrix}1 & 2 & 3\\ 2 & 1 & 0\\ 1 & -1 & \mathrm{i}\end{bmatrix}&=\det\begin{bmatrix}1 & 0\\ -1 & \mathrm{i}\end{bmatrix}-2\cdot\det\begin{bmatrix}2 & 3\\ -1 & \mathrm{i}\end{bmatrix}+\det\begin{bmatrix}2 & 3\\ 1 & 0\end{bmatrix}\\ &=\mathrm{i}-2(2\mathrm{i}+3)-3=-3\mathrm{i}-9\end{aligned}\tag{6.6.230}$$

Or the reader can check in Maple™ 4.00b by using:

```
>with(linalg):
>det(array([[1,2,3],[2,1,0],[1,-1,I]]));
```

The calculation determined above is therefore "exponential" as if for example we must calculate the determinant of a square matrix of order (dimension) $n=10$, then the determinant will be developed in a sum of 10 terms, which each contains the determinant of a matrix of dimension $n=9$, which is a cofactor of the starting matrix. If we develop any of this determinant, we get a sum of 9 determinants where each contains the determinant of a matrix of dimension $n=8$. At this level, there is therefore 90 determinants of matrices of dimension 8 to calculate. The process could continue until it remains only determinant of order 2. And therefore we guess that the number of determinants of order 2 is important!

P10. As we will prove it during our study of the spectral theorem further below at page 2004, for a positive definite matrix M we have:

$$\det(M)=\prod_i \lambda_i>0 \tag{6.6.231}$$

where the λ_i are the eigenvalues of the matrix M. And for a definite semi-positive matrix M we have:

$$\det(M)=\prod_i \lambda_i \geq 0 \tag{6.6.232}$$

Definition (#6.6.260): Given m,n two positive integers and A a $m\times n$ matrix with coefficients in $\mathbb{C}$. For any $k\leq \min(m,n)$ a "minor of order k" is a determinant of A of the type:

$$\det\begin{bmatrix} a_{i_1,j_1} & \cdots & a_{i_1,j_k} \\ \vdots & \ddots & \vdots \\ a_{i_k,j_1} & \cdots & a_{i_k,j_k} \end{bmatrix} \tag{6.6.233}$$

with $1\leq i_1<\ldots\leq m$ and $1\leq j_1<\ldots<j_k\leq n$.

In the particular case of a matrix of order $n>1$ the definition is simpler: the minor M_{ij} of the element a_{ij} is the determinant of the matrix of order $n-1$ that we get by remove the row i and the column j. Therefore, to calculate the minor of an element, we remove the line and the column to which the element belongs to, and we calculate the determinant of the remaining square matrix.

Remark

The Leibniz formula of determinants is not the way you computer libraries calculate determinants. It is more of a theoretical tool, in fact it is probably one of the slowest ways to calculate the determinant. Gaussian Elimination (see section Numerical Methods page 6305) is a fast and relatively simple way to do such a calculation!

6.6.3.4.1 Derivative of a Determinant relatively to a parameter

Let us see now a result that will be quite useful to us in the section General Relativity:

Given a square matrix $n\times n$ with functions $g_{ij}:\mathbb{R}\mapsto\mathbb{R}$ that can be derivate at least one time. Let us put $g:=\det(G)$ with $G=(g_{ij})$. We want to calculate $\mathrm{d}_t g$. Given g_i the i-th column vector of the matrix G. Let us use the formula:

$$g=\det(g_1,\ldots,g_n)=\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)g_{\sigma_{\sigma(1),1}}\cdot\ldots\cdot g_{\sigma(n),n} \tag{6.6.234}$$

Knowing that the derivative of $g_{\sigma(1),1}\cdot\ldots\cdot g_{\sigma(n),n}$ is (derivative of n products):

$$\begin{aligned}&\frac{\mathrm{d}g_{\sigma(1),1}}{\mathrm{d}t}\cdot g_{\sigma(2),2}\cdots g_{\sigma(n),n}+g_{\sigma(1),1}\cdot\frac{\mathrm{d}g_{\sigma(2),2}}{\mathrm{d}t}\cdot g_{\sigma(3),3}\cdot\ldots\cdot g_{\sigma(n),n}+\ldots\\&\quad+g_{\sigma(1),1}\cdot\ldots\cdot g_{\sigma(n-1),n-1}\cdot\frac{\mathrm{d}g_{\sigma(n),n}}{\mathrm{d}t}\end{aligned} \tag{6.6.235}$$

Therefore we have:

$$\begin{aligned}\frac{\mathrm{d}g}{\mathrm{d}t}=&\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)\cdot\frac{\mathrm{d}g_{\sigma(1),1}}{\mathrm{d}t}\cdot g_{\sigma(2),2}\cdot\ldots\cdot g_{\sigma(n),n}+\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)\cdot g_{\sigma(1),1}\cdot\frac{\mathrm{d}g_{\sigma(2),2}}{\mathrm{d}t}\cdot g_{\sigma(3),3}\cdot\ldots\cdot g_{\sigma(n),n}\\&+\ldots+\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)\cdot g_{\sigma(1),1}\cdot\ldots\cdot g_{\sigma(n-1),n-1}\cdot\frac{\mathrm{d}g_{\sigma(n),n}}{\mathrm{d}t}\end{aligned}\tag{6.6.236}$$

If we take a look closely to the first above sum, we notice that:

$$\sum_{\sigma\in S_n}\varepsilon(\sigma)\cdot\frac{\mathrm{d}g_{\sigma(1),1}}{\mathrm{d}t}\cdot g_{\sigma(2),2}\cdot\ldots\cdot g_{\sigma(n),n}=\det(g'_1,g_2,\ldots,g_n)\tag{6.6.237}$$

where g'_1 is the derivative of the vector g_1. Same for the following sums. Therefore:

$$\frac{\mathrm{d}g}{\mathrm{d}t}=\det(g'_1,g_2,\ldots,g_n)+\det(g_1,g'_2,\ldots,g_n)+\ldots+\det(g_1,g_2,\ldots,g'_n)\tag{6.6.238}$$

Let us develop again. Let us consider the term $\det(g'_1,g_2,\ldots,g_n)$ above. If we develop it relatively to the first column, we get:

$$\det(g'_1,g_2,\ldots,g_n)=\sum_{i=1}^{n}(-1)^{1+i}\cdot\frac{\mathrm{d}g_{i,1}}{\mathrm{d}t}\cdot\det(G_{i,1})\tag{6.6.239}$$

Also, by developing the j-term of the above sum relatively to the j-th column, we get:

$$\det(g_1,\ldots,g'_j,\ldots,g_n)=\sum_{i=1}^{n}(-1)^{j+i}\cdot\frac{\mathrm{d}g_{i,j}}{\mathrm{d}t}\cdot\det(G_{i,j})\tag{6.6.240}$$

If we put:

$$\alpha_{ij}:=(-1)^{i+j}\cdot\det(G_{i,j})\tag{6.6.241}$$

We get:

$$\frac{\mathrm{d}g}{\mathrm{d}t}=\sum_{j=1}^{n}\sum_{i=1}^{n}\alpha_{ij}\cdot\frac{\mathrm{d}g_{i,j}}{\mathrm{d}t}\tag{6.6.242}$$

Which is written in tensor notation (see section Tensor Calculus page 2039):

$$\frac{\mathrm{d}g}{\mathrm{d}t}=\alpha_{ij}\cdot\frac{\mathrm{d}g_{i,j}}{\mathrm{d}t}\tag{6.6.243}$$

We also have:

$$b_{ji}=\frac{1}{\det(G)}\cdot(-1)^{i+j}\cdot\det(G_{i,j})=\frac{\alpha_{ij}}{\det(G)}=\frac{\alpha_{ij}}{g}\tag{6.6.244}$$

where b_{ji} is the coefficient being at the row j-th, column i-th of the matrix G^{-1}. Let us change the notation such that:

$$g^{ij}=b_{ji}=\frac{\alpha_{ij}}{g}\tag{6.6.245}$$

The expression of the derivative is then finally:

$$\frac{\mathrm{d}g}{\mathrm{d}t}=g\cdot\sum_{j=1}^{n}\sum_{i=1}^{n}g^{ij}\cdot\frac{\mathrm{d}g_{i,j}}{\mathrm{d}t} \tag{6.6.246}$$

which is written in tensor notation:

$$\frac{\mathrm{d}g}{\mathrm{d}t}=g\cdot g^{ij}\cdot\frac{\mathrm{d}g_{i,j}}{\mathrm{d}t} \tag{6.6.247}$$

This result, finally quite simple, we will be helpful to us in the section of Tensor Calculus to build the tools necessary for the study of General Relativity and in the context of the determination of Einstein field equations. It is therefore appropriate to remember it!

6.6.3.4.2 Derivative of logarithm of a determinant

Let $M\in\mathbb{R}^{n\times n}$ be a square matrix. For a function $f:\mathbb{R}^{n\times n}\mapsto\mathbb{R}$, define its derivative f' as an $n\times n$ matrix where the entry in row i and column j is $\partial f/\partial m_{ij}$.

For some functions f, the derivative f' has a nice form. We will show now a matrix derivation that we will meet in the section of Numerical Methods during our study of Gaussian Mixture Model and Factor Analysis:

$$[\log(\det(M))]'=\frac{\mathrm{d}\log(\det(M))}{\mathrm{d}M}=(M^{-1})^T \tag{6.6.248}$$

Here, we restrict the domain of the function to M with positive determinant (typically the case of variance-covariance matrices!). Notice that it is not intuitive that the derivative of a scalar function of a matrix is equal to a matrix...

Before we get move to the proof, we need to recall some terms. For a matrix M:

- The (i,j) minor of M, denoted $\det(M_{ij})$, is the determinant of the $(n-1)\times(n-1)$ matrix that remains after removing the ith row and jth column from M
- The cofactor matrix of M, denoted C, is an $n\times n$ matrix such that $C_{ij}=(-1)^{i+j}\det(M_{ij})$
- The adjugate matrix of M, denoted $\text{adj}(M)=C^T=((-1)^{i+j}\det(M_{ij}))^T_{1\leq i,j\leq n}$, is simply the transpose of C.

These terms are useful because they related to both matrix determinants and inverses. If M is invertible, then as we have proved earlier above:

$$M^{-1}=\frac{1}{\det(M)}\text{adj}(M)=\frac{1}{\det(M)}C^T \tag{6.6.249}$$

so:

$$\left(M^{-1}\right)^T_{ij}=\frac{1}{\det(M)}C_{ij} \tag{6.6.250}$$

On the other hand, by the cofactor expansion theorem of the determinant proved earlier above (as for a symmetric matrix $C=C^T$):

$$\det(M)=\sum_{j=1}^{n}(-1)^{i+j}\cdot m_{ij}\cdot\det(M_{ij})=\sum_{j=1}^{n}m_{ij}C_{ij} \tag{6.6.251}$$

So by the derivative product rule:

$$\frac{\partial(\det(M))}{\partial m_{ij}}=\sum_{j=1}^{n}\frac{\partial m_{ij}}{\partial m_{ik}}C_{ij}+m_{ij}\frac{\partial C_{ij}}{\partial m_{ik}} \tag{6.6.252}$$

If $k\neq j$, then $\frac{\partial m_{ij}}{\partial X_{ik}}=0$, otherwise it is equal to 1. This means that the first term above reduces to C_{ik}. For any k, the elements of M which affect C_{ij} are those which do not lie on row i or column j. Hence, $\partial C_{ij}/\partial m_{ik}=0$ for all j! Therefore:

$$\frac{\partial(\det(M))}{\partial m_{ij}}=C_{ij} \tag{6.6.253}$$

Putting all this together with an application of the derivative chain rule, we get (using the for the last equality the relation 6.6.3.4.2):

$$[\log(\det(M))]'_{ij}=\frac{1}{\det(M)}\frac{\partial(\det(M))}{\partial m_{ij}}=\frac{1}{\det(M)}C_{ij}=\left(M^{-1}\right)^T_{ij} \tag{6.6.254}$$

as required!

6.6.3.4.3 Cramer's rule

Let us first solve a simple general 2 by 2 linear system using substitution to see how Cramer's rule out pops (this will be considered as an informal proof obviously!).

For this purpose we start with the following system (don't forget that such a system is traditionally written $A\vec{x}=\vec{b}$):

$$\begin{aligned}a_1x+b_1y&=c_1\\a_2x+b_2y&=c_2\end{aligned} \tag{6.6.255}$$

Multiplying both sides of the first equation by a_2, and both sides of the second equation by a_1, then subtracting, we find that:

$$(a_1b_2-b_1a_2)y=a_1c_2-c_1a_2 \tag{6.6.256}$$

Assuming that $a_1b_2-b_1a_2$ is not 0, we find that:

$$y=\frac{a_1c_2-c_1a_2}{a_1b_2-b_1a_2}=\frac{\begin{vmatrix}a_1&c_1\\a_2&c_2\end{vmatrix}}{\begin{vmatrix}a_1&b_1\\a_2&b_2\end{vmatrix}} \tag{6.6.257}$$

The formula for x can be derived similarly so that we have:

$$x=\frac{\begin{vmatrix}c_1 & b_1\\ c_2 & b_2\end{vmatrix}}{\begin{vmatrix}a_1 & b_1\\ a_2 & b_2\end{vmatrix}}=\frac{c_1b_2-b_1c_2}{a_1b_2-b_1a_2},\qquad y=\frac{\begin{vmatrix}a_1 & c_1\\ a_2 & c_2\end{vmatrix}}{\begin{vmatrix}a_1 & b_1\\ a_2 & b_2\end{vmatrix}}=\frac{a_1c_2-c_1a_2}{a_1b_2-b_1a_2} \tag{6.6.258}$$

If we denote x by x_1 and y by x_2, then we see that we have:

$$x_k=\frac{\det(A_k)}{\det(A)} \tag{6.6.259}$$

where we define A_k to be the $n\times n$ matrix obtained by replacing the k-th column of A by the inhomogeneous term $\vec{b}$.

The rules for 3×3 matrices are similar. Given:

$$\begin{aligned}a_1x+b_1y+c_1z&=d_1\\ a_2x+b_2y+c_2z&=d_2\\ a_3x+b_3y+c_3z&=d_3\end{aligned} \tag{6.6.260}$$

which in matrix notation is:

$$\begin{bmatrix}a_1 & b_1 & c_1\\ a_2 & b_2 & c_2\\ a_3 & b_3 & c_3\end{bmatrix}\begin{pmatrix}x\\ y\\ z\end{pmatrix}=\begin{pmatrix}d_1\\ d_2\\ d_3\end{pmatrix} \tag{6.6.261}$$

Then the values of x, y and z (after some boring algebra) can be found as follows:

$$x=\frac{\begin{vmatrix}d_1 & b_1 & c_1\\ d_2 & b_2 & c_2\\ d_3 & b_3 & c_3\end{vmatrix}}{\begin{vmatrix}a_1 & b_1 & c_1\\ a_2 & b_2 & c_2\\ a_3 & b_3 & c_3\end{vmatrix}},\quad y=\frac{\begin{vmatrix}a_1 & d_1 & c_1\\ a_2 & d_2 & c_2\\ a_3 & d_3 & c_3\end{vmatrix}}{\begin{vmatrix}a_1 & b_1 & c_1\\ a_2 & b_2 & c_2\\ a_3 & b_3 & c_3\end{vmatrix}},\quad z=\frac{\begin{vmatrix}a_1 & b_1 & d_1\\ a_2 & b_2 & d_2\\ a_3 & b_3 & d_3\end{vmatrix}}{\begin{vmatrix}a_1 & b_1 & c_1\\ a_2 & b_2 & c_2\\ a_3 & b_3 & c_3\end{vmatrix}} \tag{6.6.262}$$

Then denoting again x by x_1, y by x_2 and z by x_3 we have again (don't forget that such a system is traditionally written $A\vec{x}=\vec{b}$):

$$x_k=\frac{\det(A_k)}{\det(A)} \tag{6.6.263}$$

where we define A_k to be the $n\times n$ matrix obtained by replacing the k-th column of A by the inhomogeneous term $\vec{b}$.

But now let us deal with the general proof. But before... some readers may argue that it is useless! In fact not really! They are some quite important applications in Tensor Calculus (for example the divergence of a tensor field that has some application in advanced General Relativity[25]), or in computing derivatives implicitly[26]. But this are all quite abstract applications. Indeed! So the reader has to know that the most well known practical application is the use in forecasting and times series analysis in business (more generally in any advanced finance field) for the study of the partial autocorrelation coefficient of autoregressive process (through the Yule-Walker equations).

---

[25] Don't look for it in this textbook!

[26] Actually also not needed to read this textbook entirely!

Theorem 6.40. If $A\vec{x}=\vec{b}$ is a linear system of equations with $\vec{x}=[x_1\,x_2\,\ldots\,x_n]^T$ and $A\in\mathbb{R}^{n\times n}$ such that $\det(A)\neq 0$ then we find the solutions:

$$x_i=\frac{\det(A_i)}{\det(A)} \tag{6.6.264}$$

where we define A_i to be the $n\times n$ matrix obtained by replacing the i-th column of A by the inhomogeneous term $\vec{b}$.

As there is a lot of different ways to make the proof of that theorem, the best an easiest one according to us is that provided by PlanetMath.org and written by someone under the pseudonym `rmilson` the 12013-03-22 (holocene calendar) for which we provide here a simple copy paste (as everything seems perfect to us and it's at the same time a very clever way to do the proof...!):

Proof 6.40.1. Since we assume that $\det(A)\neq 0$, by the properties of the determinant we know that A is invertible.

We claim that this implies that the equation $A\vec{x}=\vec{b}$ has a unique solution. Note that $A^{-1}\vec{b}$ is a solution since:

$$A(A^{-1}\vec{b})=(AA^{-1})\vec{b}=\vec{b} \tag{6.6.265}$$

so we know that a solution exists.

Let $\vec{s}$ be an arbitrary solution to the equation, so $A\vec{s}=\vec{b}$. But then:

$$\vec{s}=(A^{-1}A)\vec{s}=A^{-1}(A\vec{s})=A^{-1}\vec{b} \tag{6.6.266}$$

so we see that $A^{-1}\vec{b}$ is the only solution.

For each integer i, $1\leq i\leq n$, let a_i denote the ith column of A, let e_i denote the ith column of the identity matrix I_n, and let X_i denote the matrix obtained from $\mathbb{1}_n$ by replacing column i with the column vector $\vec{x}$.

We know that for any matrices A, B that the kth column of the product AB is simply the product of A and the kth column of B. Also observe that:

$$Ae_k=a_k \tag{6.6.267}$$

for $k=1\ldots n$. Thus, by multiplication, we have:

$$\begin{aligned}AX_i&=A(\vec{e}_1,\ldots,\vec{e}_{i-1},\vec{x},\vec{e}_{i+1},\ldots,\vec{e}_n)\\&=(A\vec{e}_1,\ldots,A\vec{e}_{i-1},A\vec{x},A\vec{e}_{i+1},\ldots,A\vec{e}_n)\\&=M_i\end{aligned} \tag{6.6.268}$$

Since X_i is $\mathbb{1}_n$ with column i replaced with $\vec{x}$, we will compute the determinant of X_i with the cofactor expansion method. For this, let us recall the cofactor expansion relation that we have just proved earlier and that was for recall:

$$\det(A_i)=\sum_{j=1}^{n}(-1)^{i+j}a_{ij}\det(A_{ij}) \tag{6.6.269}$$

can be used to calculated the determinant only for the cofactor (row) $j=i$ such that for X_i:

$$\det(X_i)=\sum_{j=1}^{n}(-1)^{i+j}x_{ij}\det(X_{ij}) \tag{6.6.270}$$

If we choose to calculate this sum only for a given row i, we know that $x_{ij}\neq 0$ only for $i=j$, then the previous relation reduce to:

$$\det(X_i)=(-1)^{i+i}x_{ii}\det(X_{ii})=(-1)^{2i}x_i\det(X_i)=1\cdot x_i\det(X_i)=x_i\det(\mathbb{1}_{n-1})=x_i\cdot 1=x_i \tag{6.6.271}$$

Thus by the multiplicative property of the determinant:

$$\det(M_i)=\det(AX_i)=\det(A)\det(X_i)=\det(A)x_i \tag{6.6.272}$$

we get:

$$x_i=\frac{\det(M_i)}{\det(A)} \tag{6.6.273}$$

and if we denote M_i by A_i we get the famous "Cramer's rule":

$$\boxed{x_i=\frac{\det(A_i)}{\det(A)}} \tag{6.6.274}$$

as required!

■ Q.E.D.

6.6.3.4.4 Determinant Cofactor and Matrix Inverse

Let us finish our study of the determinants with the "icing on the cake" by giving a very important relation in many fields of engineering, physics and mathematics that connects the inverse of the coefficients of a matrix with miners of order n (we will use this relation further below).

Given $A\in M_n(\mathbb{C})$ an invertible matrix (non singular). Let us write $A=(a_{ij})$ and $A^{-1}=(b_{ij})$. Then:

$$\boxed{b_{ij}=\frac{1}{\det(A)}\cdot(-1)^{i+j}\cdot\det(A_{ji})} \tag{6.6.275}$$

Proof 6.40.2. Let us denote by a_k the k-th column vector of the matrix A. Knowing that $A\cdot A^{-1}=\mathbb{1}$ (under known assumptions), we have (trivial):

$$e_j=\sum_{k=1}^{n}b_{kj}a_k \tag{6.6.276}$$

Let us calculate now $\det(a_1,\ldots,a_{k-1},e_j,a_{k+1},\ldots,a_n)$. First by developing relatively to the k-th column we found (as only one of the coefficient of e_j is not null and that the unique non-null one is equal to the unit):

$$\det(a_1,\ldots,a_{k-1},e_j,a_{k+1},\ldots,a_n)=(-1)^{j+k}\det(A_{jk}) \quad (6.6.277)$$

Furthermore (properties of the determinant):

$$\begin{aligned}&\det(a_1,\ldots,a_{k-1},e_j,a_{k+1},\ldots,a_n)=\det\left(1,\ldots,a_{k-1},\sum_{l=1}^{n}b_{lj}a_l,a_{k+1},\ldots,a_n\right)\\&=\sum_{l=1}^{n}b_{lj}\underbrace{\det(a_1,\ldots,a_{k-1},a_l,a_{k+1},\ldots,a_n)}_{=0\text{ if } l\neq k}=b_{kj}\det(A)\end{aligned} \quad (6.6.278)$$

Therefore:

$$(-1)^{j+k}\det(A_{jk})=b_{kj}\det(A) \quad (6.6.279)$$

That is to say:

$$\boxed{b_{kj}=\frac{1}{\det(A)}(-1)^{j+k}\det(A_{jk})} \quad (6.6.280)$$

That later relation is sometimes denoted:

$$A^{-1}=\frac{1}{\det(A)}\text{adj}(A) \quad (6.6.281)$$

where "adj" means adjacent.

■ Q.E.D.

✍**Examples:**

E1. Inverse of a general 2×2 matrix:

$$\begin{bmatrix}a & b\\ c & d\end{bmatrix}^{-1}=\frac{1}{ad-bc}\begin{bmatrix}d & -b\\ -c & a\end{bmatrix} \quad (6.6.282)$$

We want to compute the inverse of the following 2×2 matrix:

$$A=\begin{bmatrix}2 & 4\\ 3 & 5\end{bmatrix} \quad (6.6.283)$$

using the cofactor method proved above!

First we compute the determinant:

$$\det(A)=|A|=2\cdot 5-4\cdot 3=10-12=-2 \quad (6.6.284)$$

and after the cofactors! We start with the first cofactor (it's very easy in the case of a 2×2 matrix as the minor is just as scalar and therefore the determinant of the minor is equal to the scalar itself!):

$$\begin{bmatrix} 2 & 4 \\ 3 & 5 \end{bmatrix}$$

$$C_{11} = (-1)^{1+1} \cdot \det(A_{11}) = (-1)^2 \cdot 5 = 5$$

Let's move to the next cofactor:

$$\begin{bmatrix} 2 & 4 \\ 3 & 5 \end{bmatrix}$$

$$C_{12} = (-1)^{1+2} \cdot \det(A_{21}) = (-1)^3 \cdot 3 = -3$$

Let's move again to the next cofactor:

$$\begin{bmatrix} 2 & 4 \\ 3 & 5 \end{bmatrix}$$

$$C_{21} = (-1)^{2+1} \cdot \det(A_{12}) = (-1)^3 \cdot 4 = -4$$

And now the last cofactor:

$$\begin{bmatrix} 2 & 4 \\ 3 & 5 \end{bmatrix}$$

$$C_{22} = (-1)^{2+2} \cdot \det(A_{22}) = (-1)^4 \cdot 2 = 2$$

To summarize all cofactors:

$$\begin{aligned} C_{11} &= (-1)^2 \cdot 5 = 5 \\ C_{12} &= (-1)^3 \cdot 3 = -3 \\ C_{21} &= (-1)^3 \cdot 4 = -4 \\ C_{22} &= (-1)^4 \cdot 2 = 2 \end{aligned} \tag{6.6.285}$$

Finally as:

$$b_{ij} = \frac{1}{\det(A)} \cdot (-1)^{i+j} \cdot \det\left(A_{ji}\right) \tag{6.6.286}$$

We have:

$$B = A^{-1} = -\frac{1}{2} \cdot \begin{bmatrix} 5 & -4 \\ -3 & 2 \end{bmatrix} = \begin{bmatrix} -5/2 & 2 \\ 3/2 & -1 \end{bmatrix} = \begin{bmatrix} -2.5 & 2 \\ 1.5 & -1 \end{bmatrix} \tag{6.6.287}$$

We see therefore that the cofactor matrix inversion method has an algorithmic complexity of order $\mathcal{O}(n!)$. It's a very expensive approach!

E2. Inverse of a general 3×3 matrix:

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}^{-1} = \frac{\begin{bmatrix} a_{22}a_{33}-a_{23}a_{32} & a_{13}a_{32}-a_{12}a_{33} & a_{12}a_{23}-a_{13}a_{22} \\ a_{23}a_{31}-a_{21}a_{33} & a_{11}a_{33}-a_{13}a_{31} & a_{13}a_{21}-a_{11}a_{23} \\ a_{21}a_{32}-a_{22}a_{31} & a_{12}a_{31}-a_{11}a_{32} & a_{11}a_{22}-a_{12}a_{21} \end{bmatrix}}{a_{11}a_{22}a_{33}+a_{21}a_{32}a_{13}+a_{31}a_{12}a_{23}-a_{11}a_{32}a_{23}-a_{31}a_{22}a_{13}-a_{21}a_{12}a_{33}} \tag{6.6.288}$$

E3. Inverse of a general 4×4 matrix:

$$A = \begin{pmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{pmatrix} \tag{6.6.289}$$

and:

$$\begin{aligned} \det(A) = & a_{11}a_{22}a_{33}a_{44}+a_{11}a_{23}a_{34}a_{42}+a_{11}a_{24}a_{32}a_{43} \\ & +a_{12}a_{21}a_{34}a_{43}+a_{12}a_{23}a_{31}a_{44}+a_{12}a_{24}a_{33}a_{41} \\ & +a_{13}a_{21}a_{32}a_{44}+a_{13}a_{22}a_{34}a_{41}+a_{13}a_{24}a_{31}a_{42} \\ & +a_{14}a_{21}a_{33}a_{42}+a_{14}a_{22}a_{31}a_{43}+a_{14}a_{23}a_{32}a_{41} \\ & -a_{11}a_{22}a_{34}a_{43}-a_{11}a_{23}a_{32}a_{44}-a_{11}a_{24}a_{33}a_{42} \\ & -a_{12}a_{21}a_{33}a_{44}-a_{12}a_{23}a_{34}a_{41}-a_{12}a_{24}a_{31}a_{43} \\ & -a_{13}a_{21}a_{34}a_{42}-a_{13}a_{22}a_{31}a_{44}-a_{13}a_{24}a_{32}a_{41} \\ & -a_{14}a_{21}a_{32}a_{43}-a_{14}a_{22}a_{33}a_{41}-a_{14}a_{23}a_{31}a_{42} \end{aligned} \tag{6.6.290}$$

then there exists an inverse matrix of A, and it is:

$$A^{-1} = \frac{1}{\det(A)} \begin{pmatrix} b_{11} & b_{12} & b_{13} & b_{14} \\ b_{21} & b_{22} & b_{23} & b_{24} \\ b_{31} & b_{32} & b_{33} & b_{34} \\ b_{41} & b_{42} & b_{43} & b_{44} \end{pmatrix} \tag{6.6.291}$$

where:

$$\begin{aligned}
b_{11} &= a_{22}a_{33}a_{44}+a_{23}a_{34}a_{42}+a_{24}a_{32}a_{43}-a_{22}a_{34}a_{43}-a_{23}a_{32}a_{44}-a_{24}a_{33}a_{42}\\
b_{12} &= a_{12}a_{34}a_{43}+a_{13}a_{32}a_{44}+a_{14}a_{33}a_{42}-a_{12}a_{33}a_{44}-a_{13}a_{34}a_{42}-a_{14}a_{32}a_{43}\\
b_{13} &= a_{12}a_{23}a_{44}+a_{13}a_{24}a_{42}+a_{14}a_{22}a_{43}-a_{12}a_{24}a_{43}-a_{13}a_{22}a_{44}-a_{14}a_{23}a_{42}\\
b_{14} &= a_{12}a_{24}a_{33}+a_{13}a_{22}a_{34}+a_{14}a_{23}a_{32}-a_{12}a_{23}a_{34}-a_{13}a_{24}a_{32}-a_{14}a_{22}a_{33}\\
b_{21} &= a_{21}a_{34}a_{43}+a_{23}a_{31}a_{44}+a_{24}a_{33}a_{41}-a_{21}a_{33}a_{44}-a_{23}a_{34}a_{41}-a_{24}a_{31}a_{43}\\
b_{22} &= a_{11}a_{33}a_{44}+a_{13}a_{34}a_{41}+a_{14}a_{31}a_{43}-a_{11}a_{34}a_{43}-a_{13}a_{31}a_{44}-a_{14}a_{33}a_{41}\\
b_{23} &= a_{11}a_{24}a_{43}+a_{13}a_{21}a_{44}+a_{14}a_{23}a_{41}-a_{11}a_{23}a_{44}-a_{13}a_{24}a_{41}-a_{14}a_{21}a_{43}\\
b_{24} &= a_{11}a_{23}a_{34}+a_{13}a_{24}a_{31}+a_{14}a_{21}a_{33}-a_{11}a_{24}a_{33}-a_{13}a_{21}a_{34}-a_{14}a_{23}a_{31}\\
b_{31} &= a_{21}a_{32}a_{44}+a_{22}a_{34}a_{41}+a_{24}a_{31}a_{42}-a_{21}a_{34}a_{42}-a_{22}a_{31}a_{44}-a_{24}a_{32}a_{41}\\
b_{32} &= a_{11}a_{34}a_{42}+a_{12}a_{31}a_{44}+a_{14}a_{32}a_{41}-a_{11}a_{32}a_{44}-a_{12}a_{34}a_{41}-a_{14}a_{31}a_{42}\\
b_{33} &= a_{11}a_{22}a_{44}+a_{12}a_{24}a_{41}+a_{14}a_{21}a_{42}-a_{11}a_{24}a_{42}-a_{12}a_{21}a_{44}-a_{14}a_{22}a_{41}\\
b_{34} &= a_{11}a_{24}a_{32}+a_{12}a_{21}a_{34}+a_{14}a_{22}a_{31}-a_{11}a_{22}a_{34}-a_{12}a_{24}a_{31}-a_{14}a_{21}a_{32}\\
b_{41} &= a_{21}a_{33}a_{42}+a_{22}a_{31}a_{43}+a_{23}a_{32}a_{41}-a_{21}a_{32}a_{43}-a_{22}a_{33}a_{41}-a_{23}a_{31}a_{42}\\
b_{42} &= a_{11}a_{32}a_{43}+a_{12}a_{33}a_{41}+a_{13}a_{31}a_{42}-a_{11}a_{33}a_{42}-a_{12}a_{31}a_{43}-a_{13}a_{32}a_{41}\\
b_{43} &= a_{11}a_{23}a_{42}+a_{12}a_{21}a_{43}+a_{13}a_{22}a_{41}-a_{11}a_{22}a_{43}-a_{12}a_{23}a_{41}-a_{13}a_{21}a_{42}\\
b_{44} &= a_{11}a_{22}a_{33}+a_{12}a_{23}a_{31}+a_{13}a_{21}a_{32}-a_{11}a_{23}a_{32}-a_{12}a_{21}a_{33}-a_{13}a_{22}a_{31}
\end{aligned} \tag{6.6.292}$$

Here is the pseudocode of the cofactor matrix inversion method:

Algorithm 2: Matrix Inversion using Determinant and Cofactor Method

```
Input: Square Matrix $A$
Output: Inverted Matrix $A^{-1}$
Function MatrixInverse($A$):
    detA ← Determinant($A$)
    if detA = 0 then return "Matrix is not invertible"

    $n$ ← number of rows/columns in $A$ as global variable

            $C[r][c] \leftarrow A[i][j]$
        end
    end
    return $C$
```

For a simple, detailed, and important practical application in the industry (because otherwise in this entire book we will rarely inverse small matrices), the reader can refer to the section of Numerical Methods in the part concerning the multiple linear regression.

Let us also indicate the following important properties where A and B are both square invertible matrices $M_n(\mathbb{C})$ and $\lambda \in \mathbb{C}$ (the first should be obvious, the second has already been presented earlier but unproven and the third one is important for the proof of the variance inflation factor that we will prove in the section of Numerical Methods on page 6398):

$$\begin{gathered}(\lambda A)^{-1}=\lambda^{-1}A^{-1}\\(A^T)^{-1}=(A^{-1})^T\\(AB)^{-1}=B^{-1}A^{-1}\end{gathered}\tag{6.6.293}$$

Let us prove the last property using the property of associativity:

Proof 6.40.3.

$$(AB)(B^{-1}A^{-1})=A(BB^{-1})A^{-1}=AA^{-1}=I_n\tag{6.6.294}$$

Which proves that $B^{-1}A^{-1}$ is indeed the inverse of AB where I_n (also denoted $\mathbb{1}$ for recall) is a diagonal matrix (also square) of dimension n.

■ Q.E.D.

6.6.3.4.5 Determinant of block-diagonal or block-triangular matrices

For our study of Factor Analysis we will need to compute the determinant of two particular type of block-triangular matrices.

First we will need to compute the determinant of block-upper-triangular matrix of the form:

$$\Gamma=\begin{bmatrix}A & B\\ \mathbb{O} & D\end{bmatrix}\tag{6.6.295}$$

where A and D are square matrices. And secondly of a block-lower-triangular matrix of the form:

$$\Gamma=\begin{bmatrix}A & \mathbb{O}\\ C & D\end{bmatrix}\tag{6.6.296}$$

However to calculate the determinant of these matrices we should first prove how to calculate the determinant of a diagonal block matrix of the following type:

$$\Gamma=\begin{bmatrix}A & \mathbb{O}\\ \mathbb{O} & \mathbb{1}\end{bmatrix}\tag{6.6.297}$$

where $\mathbb{1}$ is in this special case a 1×1, that is, $\mathbb{1}=1$. Suppose A is $k\times k$. Then Γ is of dimension $(k+1)(k+1)$.

For the proof, we will use the relation derived earlier above:

$$\det(A)=\sum_{\sigma\in\mathcal{S}_n}\varepsilon(\sigma)\prod_{i=1}^{n}a_{i\sigma(i)}\tag{6.6.298}$$

Proof 6.40.4. So we need to compute:

$$\det(\Gamma)=\sum_{\sigma\in\mathcal{S}_{k+1}}\varepsilon(\sigma)\prod_{i=1}^{k+1}\Gamma_{i\sigma(i)} \tag{6.6.299}$$

where $\mathcal{S}$ is the set of all permutations of the first $k+1$ natural numbers.

In the special case above we can rewrite this as:

$$\det(\Gamma)=\sum_{\sigma\in\mathcal{S}_{k+1}}\varepsilon(\sigma)\underbrace{\Gamma_{(k+1)\sigma(k+1)}}_{=1}\underbrace{\prod_{i=1}^{k}\Gamma_{i\sigma(i)}}_{\prod_{i=1}^{k}A_{i\sigma(i)}}=\sum_{\sigma\in\mathcal{S}_{k}}\varepsilon(\sigma)\prod_{i=1}^{k}A_{i\sigma(i)}=\det(A) \tag{6.6.300}$$

Remark

Let us recall to help to understand what we just did that we are typically in a situation similar to the following below where $a_{33}=1, a_{31}=a_{13}=a_{23}=a_{32}=0$:

$$\begin{aligned}\det(A)&=\det\begin{pmatrix}a_{11}&a_{12}&a_{13}\\a_{21}&a_{22}&a_{23}\\a_{31}&a_{32}&a_{33}\end{pmatrix}=\sum_{\sigma\in\mathcal{S}_4}\varepsilon(\sigma)\prod_{i=1}^{4}a_{i\sigma(i)}\\&=a_{11}\det\begin{pmatrix}a_{22}&a_{23}\\a_{32}&a_{33}\end{pmatrix}-a_{12}\det\begin{pmatrix}a_{21}&a_{23}\\a_{31}&a_{33}\end{pmatrix}+a_{13}\det\begin{pmatrix}a_{21}&a_{22}\\a_{31}&a_{32}\end{pmatrix}\\&=a_{11}a_{22}a_{33}-a_{11}a_{23}a_{32}-a_{12}a_{21}a_{33}+a_{12}a_{23}a_{31}+a_{13}a_{21}a_{32}-a_{13}a_{22}a_{31}\end{aligned} \tag{6.6.301}$$

From the above formula, each term is in the form of $a_{1j_1}a_{2j_2}a_{3j_3}$ where the second indices j_1,j_2,j_3 is a permutation of $1,2,3$. For example, the first term has $1,2,3$ as the second indices; the second term has $1,3,2$; the third term has $2,1,3$, etc.

The sign of each term is the sign of the permutation. For example, the sign of $1,2,3$ is clearly 1. For the second term, $1,3,2$ is obtained from $1,2,3$ by one transposition $2,3\rightarrow 3,2$, so the sign is -1, etc.

We see obviously that in the case $a_{33}=1, a_{31}=a_{13}=a_{23}=a_{32}=0$, the above relation reduces to:

$$\begin{aligned}\det(A)&=\det\begin{pmatrix}a_{11}&a_{12}&0\\a_{21}&a_{22}&0\\0&0&1\end{pmatrix}=\sum_{\sigma\in\mathcal{S}_4}\varepsilon(\sigma)\prod_{i=1}^{4}a_{i\sigma(i)}\\&=a_{11}\det\begin{pmatrix}a_{22}&0\\0&1\end{pmatrix}-a_{12}\det\begin{pmatrix}a_{21}&0\\0&1\end{pmatrix}+0\det\begin{pmatrix}a_{21}&a_{22}\\0&0\end{pmatrix}\\&=a_{11}a_{22}\cdot 1-a_{11}\cdot 0\cdot 0-a_{12}a_{21}\cdot 1+a_{12}\cdot 0\cdot 0+0\cdot a_{21}\cdot 0-0\cdot a_{22}\cdot 0\\&=a_{11}a_{22}-a_{12}a_{21}\end{aligned} \tag{6.6.302}$$

The result for the case in which $\mathbb{1}$ is not 1×1 is proved recursively. For example, if $\mathbb{1}$ is 2×2,

we have:

$$\det\begin{bmatrix} A & \mathbb{O} \\ \mathbb{O} & \mathbb{1} \end{bmatrix} = \det\begin{bmatrix} \begin{bmatrix} A & 0 \\ 0 & 1 \end{bmatrix} & 0 \\ 0 & 1 \end{bmatrix} = \det\begin{bmatrix} A & 0 \\ 0 & 1 \end{bmatrix} = \det(A) \tag{6.6.303}$$

and analogously for larger dimensions.

■ Q.E.D.

The proof for the case in which:

$$\Gamma = \begin{bmatrix} \mathbb{1} & \mathbb{O} \\ \mathbb{O} & \mathbb{A} \end{bmatrix} \tag{6.6.304}$$

is similar to the one just provided.

Ok now that we have this result, let us prove the following determinant:

$$\det(\Gamma) = \det\begin{bmatrix} A & \mathbb{O} \\ C & D \end{bmatrix} = \det(A)\det(D) \tag{6.6.305}$$

Proof 6.40.5. Let us assume that A is $k \times k$ and D is $l \times l$, so that C is $l \times k$ and $\mathbb{O}$ is $k \times l$. In what follows, we will denote by $\mathbb{1}_k$ a $k \times k$ identity matrix and by $\mathbb{O}_{lk}$ an $l \times k$ zero matrix. Note that (in the purpose to decompose the above matrix Γ in product of triangular block matrices!):

$$\begin{aligned}
&\begin{bmatrix} A & \mathbb{O}_{kl} \\ \mathbb{O}_{lk} & \mathbb{1}_l \end{bmatrix} \begin{bmatrix} \mathbb{1}_k & \mathbb{O}_{kl} \\ C & \mathbb{1}_l \end{bmatrix} \begin{bmatrix} \mathbb{1}_k & \mathbb{O}_{kl} \\ \mathbb{O}_{lk} & D \end{bmatrix} \\
&= \begin{bmatrix} A\mathbb{1}_k + \mathbb{O}_{kl}C & A\mathbb{O}_{kl} + \mathbb{O}_{kl}\mathbb{1}_l \\ \mathbb{O}_{lk}\mathbb{1}_k + \mathbb{1}_l C & \mathbb{O}_{lk}\mathbb{O}_{kl} + \mathbb{1}_l\mathbb{1}_l \end{bmatrix} \begin{bmatrix} \mathbb{1}_k & \mathbb{O}_{kl} \\ \mathbb{O}_{lk} & D \end{bmatrix} \\
&= \begin{bmatrix} A & \mathbb{O}_{kl} \\ C & \mathbb{1}_l \end{bmatrix} \begin{bmatrix} \mathbb{1}_k & \mathbb{O}_{kl} \\ \mathbb{O}_{lk} & D \end{bmatrix} \\
&= \begin{bmatrix} A\mathbb{1}_k + \mathbb{O}_{kl}\mathbb{O}_{lk} & A\mathbb{O}_{kl} + \mathbb{O}_{kl}D \\ C\mathbb{1}_k + \mathbb{1}_l\mathbb{O}_{kl} & C\mathbb{O}_{kl} + \mathbb{1}_l D \end{bmatrix} \\
&= \begin{bmatrix} A & \mathbb{O} \\ C & D \end{bmatrix}
\end{aligned} \tag{6.6.306}$$

Thus, similarly to the previous proof with the diagonal block matrices and triangular block matrices:

$$\begin{aligned}
\det(\Gamma) = \det\begin{bmatrix} A & \mathbb{O} \\ C & D \end{bmatrix} &= \det\left(\begin{bmatrix} A & \mathbb{O}_{kl} \\ \mathbb{O}_{lk} & \mathbb{1}_l \end{bmatrix} \begin{bmatrix} \mathbb{1}_k & \mathbb{O}_{kl} \\ C & \mathbb{1}_l \end{bmatrix} \begin{bmatrix} \mathbb{1}_k & \mathbb{O}_{kl} \\ \mathbb{O}_{lk} & D \end{bmatrix}\right) \\
&= \det\left(\begin{bmatrix} A & \mathbb{O}_{kl} \\ \mathbb{O}_{lk} & \mathbb{1}_l \end{bmatrix}\right) \det\left(\begin{bmatrix} \mathbb{1}_k & \mathbb{O}_{kl} \\ C & \mathbb{1}_l \end{bmatrix}\right) \det\left(\begin{bmatrix} \mathbb{1}_k & \mathbb{O}_{kl} \\ \mathbb{O}_{lk} & D \end{bmatrix}\right) \\
&= \det(A)\det(\mathbb{1}_l)\det(\mathbb{1}_k)\det(\mathbb{1}_l)\det(\mathbb{1}_l)\det(D) \\
&= \det(A)\det(D)
\end{aligned} \tag{6.6.307}$$

■ Q.E.D.

6.6.3.4.6 Inverse and Determinant of a partitioned symmetric matrix

We will prove here a set of relations that we will need (once again...) for our study of Factor Analysis in the section of Statistics.

Let us divide an $n \times n$ symmetric matrix A into four blocks:

$$A=\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \tag{6.6.308}$$

The inverse matrix $B=A^{-1}$ can also be divided into four blocks:

$$B=A^{-1}=\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \tag{6.6.309}$$

Here we assume the dimensionalities of these blocks are:

- A_{11} and B_{11} are $p \times p$
- A_{22} and B_{22} are $q \times q$
- $A_{12}=A_{21}^T$ and $B_{12}=B_{21}^T$ are $p \times q$

with $p+q=n$.

Then what we want to prove first (and after we will be able to focus on the inverse determinant problem) is that the components of the inverse of a partitioned symmetric matrix are given by:

$$\begin{aligned}
B_{11}&=\left(A_{11}-A_{12}A_{22}^{-1}A_{21}\right)^{-1}=A_{11}^{-1}+A_{11}^{-1}A_{12}\left(A_{22}-A_{21}A_{11}^{-1}A_{12}\right)^{-1}A_{21}A_{11}^{-1}\\
B_{22}&=\left(A_{22}-A_{21}A_{11}^{-1}A_{12}\right)^{-1}=A_{22}^{-1}+A_{22}^{-1}A_{21}\left(A_{11}-A_{12}A_{22}^{-1}A_{21}\right)^{-1}A_{12}A_{22}^{-1}\\
B_{21}&=-A_{22}^{-1}A_{21}\left(A_{11}-A_{12}A_{22}^{-1}A_{21}\right)^{-1}\\
B_{12}&=-A_{11}^{-1}A_{12}\left(A_{22}-A_{21}A_{11}^{-1}A_{12}\right)^{-1}
\end{aligned} \tag{6.6.310}$$

ie (it is in this form that we found it in most textbooks):

$$\boxed{B=A^{-1}=\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix}=\begin{bmatrix} \left(A_{11}-A_{12}A_{22}^{-1}A_{21}\right)^{-1} & -A_{11}^{-1}A_{12}\left(A_{22}-A_{21}A_{11}^{-1}A_{12}\right)^{-1} \\ -A_{22}^{-1}A_{21}\left(A_{11}-A_{12}A_{22}^{-1}A_{21}\right)^{-1} & \left(A_{22}-A_{21}A_{11}^{-1}A_{12}\right)^{-1} \end{bmatrix}} \tag{6.6.311}$$

Remark

The term $A_{11}-A_{12}A_{22}^{-1}A_{21}$ seems to be named the "Schur complement" of A_{22} in A. Same for the term $A_{22}-A_{21}A_{11}^{-1}A_{12}$ that seems also be named "Schur complement" of A_{11} in A.

Proof 6.40.6. We start with:

$$\begin{aligned}
\mathbb{1}_n=AA^{-1}=AB&=\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix}\\
&=\begin{bmatrix} A_{11}B_{11}+A_{12}B_{21} & A_{11}B_{12}+A_{12}B_{22} \\ A_{21}B_{11}+A_{22}B_{21} & A_{21}B_{12}+A_{22}B_{22} \end{bmatrix}=\begin{bmatrix} \mathbb{1}_p & 0 \\ 0 & \mathbb{1}_q \end{bmatrix}
\end{aligned} \tag{6.6.312}$$

Let us equate each of the four blocks to get:

$$\begin{array}{lll} A_{11}B_{11}+A_{12}B_{21}=\mathbb{1}_p & \text{then} & B_{11}=A_{11}^{-1}-A_{11}^{-1}A_{12}B_{21} \\ A_{11}B_{12}+A_{12}B_{22}=\mathbb{0} & \text{then} & B_{12}=-A_{11}^{-1}A_{12}B_{22} \\ A_{21}B_{11}+A_{22}B_{21}=\mathbb{0} & \text{then} & B_{21}=-A_{22}^{-1}A_{21}B_{11} \\ A_{21}B_{12}+A_{22}B_{22}=\mathbb{1}_q & \text{then} & B_{22}=A_{22}^{-1}-A_{22}^{-1}A_{21}B_{12} \end{array} \tag{6.6.313}$$

Plug B_{21} into B_{11} to get:

$$B_{11}=A_{11}^{-1}+A_{11}^{-1}A_{12}A_{22}^{-1}A_{21}B_{11} \tag{6.6.314}$$

Solve for B_{11} to get:

$$B_{11}=\left(A_{11}-A_{12}A_{22}^{-1}A_{21}\right)^{-1} \tag{6.6.315}$$

Applying the Woodburry matrix identity (see below page 2035) given for recall by:

$$(A+UBV^T)^{-1}=A^{-1}-A^{-1}U(B^{-1}+V^TA^{-1}U)^{-1}V^TA^{-1} \tag{6.6.316}$$

to this expression we also get the other expression in the theorem, i.e.:

$$A_{11}^{-1}+A_{11}^{-1}A_{12}\left(A_{22}-A_{21}A_{11}^{-1}A_{12}\right)^{-1}A_{21}A_{11}^{-1} \tag{6.6.317}$$

Similarly we can get:

$$\begin{aligned} B_{22}&=\left(A_{22}-A_{21}A_{11}^{-1}A_{12}\right)^{-1} \\ B_{21}&=-A_{22}^{-1}A_{21}\left(A_{11}-A_{12}A_{22}^{-1}A_{21}\right)^{-1} \\ B_{12}&=-A_{11}^{-1}A_{12}\left(A_{22}-A_{21}A_{11}^{-1}A_{12}^{-1}\right)^{-1} \end{aligned} \tag{6.6.318}$$

■ Q.E.D.

Let us see now how to calculate the determinant of a partitioned symmetric matrix, given by:

$$\det(A)=\det\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22}\end{bmatrix}=\det(A_{22})\det(A_{11}-A_{12}A_{22}^{-1}A_{21})=\det(A_{11})\det(A_{22}-A_{21}A_{11}^{-1}A_{12}) \tag{6.6.319}$$

Proof 6.40.7. First, let us consider a matrix of the form:

$$\begin{bmatrix} A & B \\ C & D\end{bmatrix} \tag{6.6.320}$$

where A,B,C,D have size $n\times n$. We start from considering multiplication on the left by a matrix such that:

$$\begin{bmatrix} A^{-1} & \mathbb{0} \\ \mathbb{0} & \mathbb{1}\end{bmatrix}\begin{bmatrix} A & B \\ C & D\end{bmatrix}=\begin{bmatrix} \mathbb{1} & A^{-1}B \\ C & D\end{bmatrix} \tag{6.6.321}$$

Now let us consider the following left multiplication:

$$\begin{bmatrix} \mathbb{1} & \mathbb{0} \\ -C & \mathbb{1}\end{bmatrix}\begin{bmatrix} \mathbb{1} & A^{-1}B \\ C & D\end{bmatrix}=\begin{bmatrix} \mathbb{1} & A^{-1}B \\ \mathbb{0} & D-CA^{-1}B\end{bmatrix} \tag{6.6.322}$$

Therefore (starting from the beginning) in one line, that means we have:

$$\left(\begin{bmatrix}\mathbb{1} & \mathbb{0}\\ -C & \mathbb{1}\end{bmatrix}\begin{bmatrix}A^{-1} & \mathbb{0}\\ \mathbb{0} & \mathbb{1}\end{bmatrix}\right)\begin{bmatrix}A & B\\ C & D\end{bmatrix}=\begin{bmatrix}\mathbb{1} & A^{-1}B\\ \mathbb{0} & D-CA^{-1}B\end{bmatrix} \tag{6.6.323}$$

So that means after rearranging:

$$\begin{bmatrix}A & B\\ C & D\end{bmatrix}=\left(\begin{bmatrix}\mathbb{1} & \mathbb{0}\\ -C & \mathbb{1}\end{bmatrix}\begin{bmatrix}A^{-1} & \mathbb{0}\\ \mathbb{0} & \mathbb{1}\end{bmatrix}\right)^{-1}\begin{bmatrix}\mathbb{1} & A^{-1}B\\ \mathbb{0} & D-CA^{-1}B\end{bmatrix} \tag{6.6.324}$$

And it is therefore quite immediate that:

$$\left(\begin{bmatrix}\mathbb{1} & \mathbb{0}\\ -C & \mathbb{1}\end{bmatrix}\begin{bmatrix}A^{-1} & \mathbb{0}\\ \mathbb{0} & \mathbb{1}\end{bmatrix}\right)^{-1}=\begin{bmatrix}A & \mathbb{0}\\ C & \mathbb{1}\end{bmatrix} \tag{6.6.325}$$

So that finally:

$$\begin{bmatrix}A & B\\ C & D\end{bmatrix}=\begin{bmatrix}A & \mathbb{0}\\ C & \mathbb{1}\end{bmatrix}\begin{bmatrix}\mathbb{1} & A^{-1}B\\ \mathbb{0} & D-CA^{-1}B\end{bmatrix} \tag{6.6.326}$$

Similarly we get:

$$\begin{bmatrix}A & B\\ C & D\end{bmatrix}=\begin{bmatrix}\mathbb{1} & B\\ \mathbb{0} & D\end{bmatrix}\begin{bmatrix}A-BD^{-1} & \mathbb{0}\\ D^{-1}C & \mathbb{1}\end{bmatrix} \tag{6.6.327}$$

To summarize:

$$\boxed{\begin{bmatrix}A & B\\ C & D\end{bmatrix}=\begin{bmatrix}A & \mathbb{0}\\ C & \mathbb{1}\end{bmatrix}\begin{bmatrix}\mathbb{1} & A^{-1}B\\ \mathbb{0} & D-CA^{-1}B\end{bmatrix}=\begin{bmatrix}\mathbb{1} & B\\ \mathbb{0} & D\end{bmatrix}\begin{bmatrix}A-BD^{-1} & \mathbb{0}\\ D^{-1}C & \mathbb{1}\end{bmatrix}} \tag{6.6.328}$$

This is a result we needed before attacking the real deal!

Indeed, according to the result above, this means that we can write:

$$\begin{aligned}A=\begin{bmatrix}A_{11} & A_{12}\\ A_{21} & A_{22}\end{bmatrix}&=\begin{bmatrix}A_{11} & 0\\ A_{21} & \mathbb{1}\end{bmatrix}\begin{bmatrix}\mathbb{1} & A_{11}^{-1}A_{12}\\ \mathbb{0} & A_{22}-A_{21}A_{11}^{-1}A_{12}\end{bmatrix}\\ &=\begin{bmatrix}\mathbb{1} & A_{12}\\ \mathbb{0} & A_{22}\end{bmatrix}\begin{bmatrix}A_{11}-A_{12}A_{22}^{-1}A_{21} & \mathbb{0}\\ A_{22}^{-1}A_{21} & \mathbb{1}\end{bmatrix}\end{aligned} \tag{6.6.329}$$

As seen above (page 1969), we have:

$$\boxed{\det(A\cdot B)=\det(A)\cdot\det(B)} \tag{6.6.330}$$

and (page 1986):

$$\det\begin{bmatrix}B & \mathbb{0}\\ X & C\end{bmatrix}=\det\begin{bmatrix}B & X\\ \mathbb{0} & C\end{bmatrix}=\det(B)\det(C) \tag{6.6.331}$$

Therefore the equality:

$$\det(A)=\det\begin{bmatrix}A_{11} & A_{12}\\ A_{21} & A_{22}\end{bmatrix}=\det(A_{22})\det(A_{11}-A_{12}A_{22}^{-1}A_{21})=\det(A_{11})\det(A_{22}-A_{21}A_{11}^{-1}A_{12}) \tag{6.6.332}$$

is proved.

■ Q.E.D.

6.6.4 Change of Basis (frames)

A basis for a vector space of dimension n is a sequence of n vectors $(\vec{e}_1,\ldots,\vec{e}_n)$ with the property that every vector in the space can be expressed uniquely as a linear combination of the basis vectors (see section Vector Calculus page 1809). The matrix representations of operators are also determined by the chosen basis! Since it is often desirable to work with more than one basis for a vector space, it is of fundamental importance in linear algebra to be able to easily transform coordinate-wise representations of vectors and operators taken with respect to one basis to their equivalent representations with respect to another basis. Such a transformation is named a "change of basis".

Let us now suppose that we move from a frame $\mathcal{E}=(\vec{e}_1,\vec{e}_2,\ldots,\vec{e}_n)$ of a space V^n to another space $\mathcal{F}=(\vec{f}_1,\vec{f}_2,\ldots,\vec{f}_n)$ of this same space sharing the same origin O. Thus in two dimension:

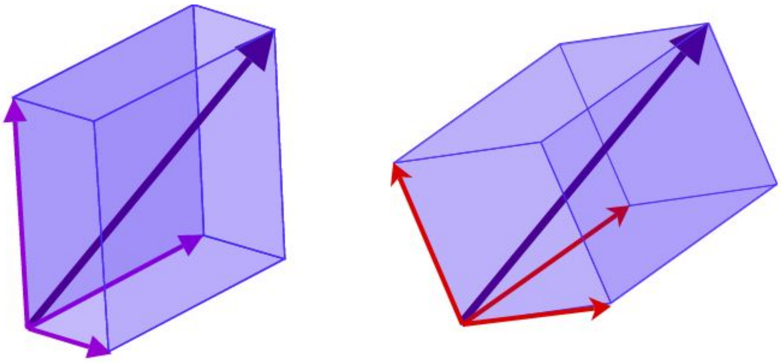

Figure 6.145: A vector represented in two different bases (purple and red arrows) (source: Wikipedia)

Let us decompose the $\vec{f}_i$ in the basis $\mathcal{E}$:

$$\begin{aligned}
\vec{f}_1 &= p_{11}\vec{e}_1+p_{21}\vec{e}_2+\ldots+p_{n1}\vec{e}_n\\
\vec{f}_2 &= p_{12}\vec{e}_1+p_{22}\vec{e}_2+\ldots+p_{n2}\vec{e}_n\\
\ldots\\
\vec{f}_n &= p_{1n}\vec{e}_1+p_{2n}\vec{e}_2+\ldots+p_{nn}\vec{e}_n
\end{aligned}\tag{6.6.333}$$

Definition (#6.6.261): We name "transition matrix" the matrix (linear application) that allows to pass from $\mathcal{E}\mapsto\mathcal{F}$ given by:

$$P=\begin{array}{c}\begin{pmatrix}p_{11} & p_{12} & \cdots & p_{1n}\\ p_{21} & \ddots & \vdots & p_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ p_{n1} & p_{n2} & \cdots & p_{nn}\end{pmatrix}\\ \underbrace{\hspace{5cm}}\\ \begin{array}{cccc}\vec{f}_1 & \vec{f}_1 & \cdots & \vec{f}_n\end{array}\end{array}\tag{6.6.334}$$

Theorem 6.41. Now let us consider the vector given by (such a notation will be more clear when the reader will deal with covariant and contravariant components in the section of Tensor Calculus at page 2059):

$$\vec{v}=x^i\vec{e}_i\tag{6.6.335}$$

So we intend to prove that the components of $y_1, y_2, \ldots, y_n$ of $\vec{v}$ in the basis $\mathcal{F}$ are given by:

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = P \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix} \quad X = PY \tag{6.6.336}$$

Thus explicitly:

$$\begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix} = P^{-1} \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} \quad Y = P^{-1}X \tag{6.6.337}$$

Remark

The matrix P is invertible (non-singular), because its columns are linearly independent (they are the vectors $\vec{f}_i$ decomposed in the basis $\mathcal{E}$ and the $\vec{f}_i$ base and the $\vec{f}_i$ are linearly independent as they form a base!).

Proof 6.41.1. Let us take the case to simplify the case $n=2$ (the proof being quite easily generalized) with $\mathcal{E} = (\vec{e}_1, \vec{e}_2)$ and $\mathcal{F} = (\vec{f}_1, \vec{f}_2)$. Then we have:

$$\begin{aligned} \vec{f}_1 &= p_{11}\vec{e}_1 + p_{21}\vec{e}_2 \\ \vec{f}_2 &= p_{12}\vec{e}_1 + p_{22}\vec{e}_2 \end{aligned} \tag{6.6.338}$$

We therefore have $\vec{v} = x^i\vec{e}_i$ and we seek to express $\vec{v}$ in the basis $\mathcal{F}$ as $\vec{v} = y^i\vec{f}_i$. We'll search the linear application that link these two relation such that:

$$x^i\vec{e}_i = y^i\vec{f}_i \tag{6.6.339}$$

Thus written in an explicit way:

$$\begin{aligned} \vec{v} &= y_1\vec{f}_1 + y_2\vec{f}_2 = y_1(p_{11}\vec{e}_1 + p_{21}\vec{e}_2) + y_2(p_{12}\vec{e}_1 + p_{22}\vec{e}_2) \\ &= p_{11}y_1\vec{e}_1 + p_{21}y_1\vec{e}_2 + p_{12}y_2\vec{e}_1 + p_{22}y_2\vec{e}_2 = (p_{11}y_1 + p_{12}y_2)\vec{e}_1 + (p_{12}\vec{y}_1 + p_{22}y_2)\vec{e}_2 \\ &= x_1\vec{e}_1 + x_2\vec{e}_2 \end{aligned} \tag{6.6.340}$$

Therefore:

$$\begin{aligned} x_1 &= p_{11}y_1 + p_{12}y_2 \\ x_2 &= p_{21}y_1 + p_{22}y_2 \end{aligned} \tag{6.6.341}$$

That is to say:

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{bmatrix} p_{11} & p_{12} \\ p_{21} & p_{22} \end{bmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \tag{6.6.342}$$

So P (if it exists) is indeed the matrix that can express the components of a vector of a basis in those of another basis such that we write in vector notation:

$$\vec{x} = P\vec{y} \tag{6.6.343}$$

■ Q.E.D.

Theorem 6.42. Let us now consider a linear application $g: V^n \mapsto V^n$. Let A be the matrix in the basis $\mathcal{E}$, and B its matrix in the basis $\mathcal{F}$ (of same dimension). Then we might have:

$$\boxed{B = P^{-1}AP} \tag{6.6.344}$$

which is equivalent:

$$BP = AP \tag{6.6.345}$$

or even:

$$A = PBP^{-1} \tag{6.6.346}$$

If there exists such a matrix P satisfying these relations, we say that A and B are "similar matrices".

Remark

Such basis changes are very useful in physics in the resolution of some systems of differential equations putted in matrix form. The change of basis can in some cases considerably simplify the resolution and by keeping at the same time the qualitative solution. The simplification is especially significant when the matrix A can be put into a diagonal form named "Weyr canonical form" and in another one named the (upper triangular) named "Jordan canonical form". It is important for theoretical reasons to know that one can always find the Jordan canonical form of a square matrix. It simplifies many abstract proofs to assume a matrix in the proof is in Jordan canonical form. The proof of that claim is actually out of the scoop of this textbook (especially because the Jordan canonical form is not well-suited to solve system of differential equation because of numerical instabilities).

Proof 6.42.1. Let us take back the fact that we proved that it was eventually possible to build a transition matrix P from the fact that:

$$\vec{v} = x^i\vec{e}_i = y^i\vec{f}_i \tag{6.6.347}$$

and let us put:

$$g(\vec{v}) = x'^i\vec{e}_i = y'^i\vec{f}_i \tag{6.6.348}$$

We have then a function that bring us to write:

$$\vec{x}\,' = A\vec{x} \qquad \vec{y}\,' = B\vec{y} \tag{6.6.349}$$

On the other hand, we have (that we proved earlier):

$$\vec{x} = P\vec{y} \qquad \vec{x}\,' = P\vec{y} \tag{6.6.350}$$

Therefore:

$$\vec{y}\,' = P^{-1}\vec{x}\,' = P^{-1}(A\vec{x}) = P^{-1}(A(P\vec{y})) = (P^{-1}AP)\vec{y} = B\vec{y} \tag{6.6.351}$$

hence:

$$B=P^{-1}AP \tag{6.6.352}$$

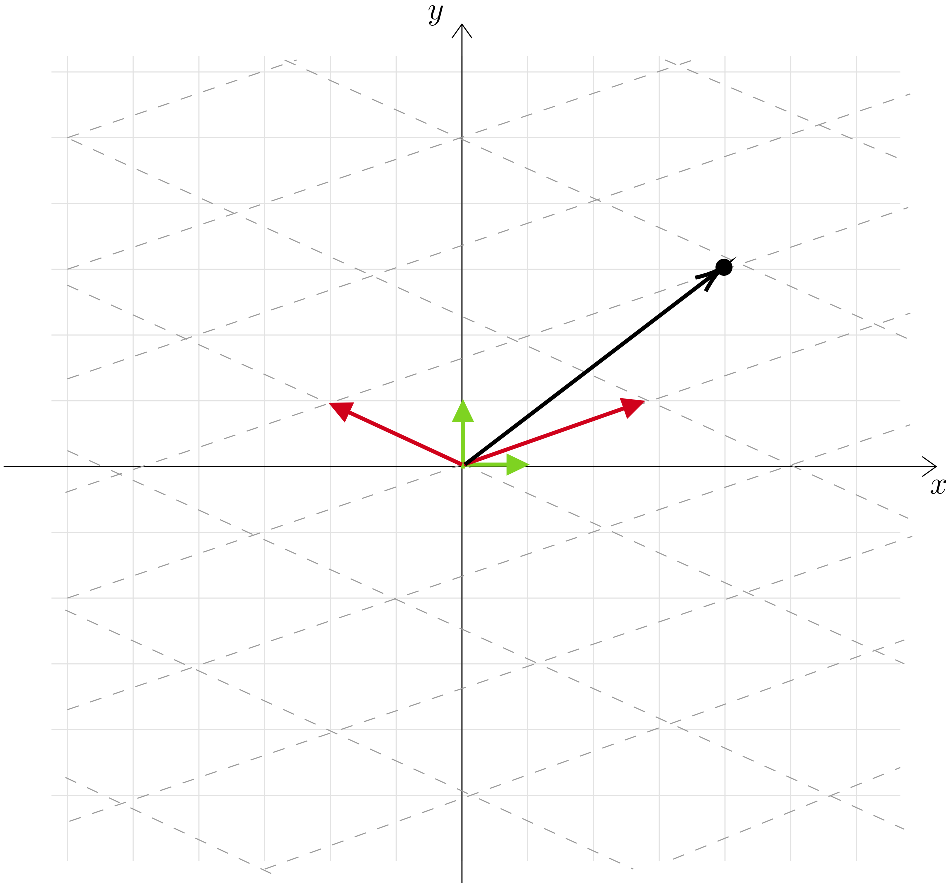
and as we saw it in our study of the determinant, the determinants of A, B are equal and therefore invariant. We will return later back on a similar formulation in our study of the Spectral Theorem below.

■ Q.E.D.

At the vocabulary level we say when we are in the presence of a such a matrix relation that: the matrix A is "conjugated" to the matrix B.

✍**Example:**

Let $B=\left\{\begin{pmatrix}1\\0\end{pmatrix},\begin{pmatrix}0\\1\end{pmatrix}\right\}$ in green in the figure below and $B'=\left\{\begin{pmatrix}3\\1\end{pmatrix},\begin{pmatrix}-2\\1\end{pmatrix}\right\}$ in red in the figure below:



The change of basis matrix form B' to B is:

$$P=\begin{bmatrix}3 & -2\\1 & 1\end{bmatrix}$$

The vector $\vec{v}$ with coordinates $\vec{v}_{B'} = \begin{pmatrix} 2 \\ 1 \end{pmatrix}$ relative to the basis B' has coordinates:

$$\vec{v}_B = \begin{bmatrix} 3 & -2 \\ 1 & 1 \end{bmatrix} \begin{pmatrix} 2 \\ 1 \end{pmatrix} = \begin{pmatrix} 4 \\ 3 \end{pmatrix}$$

relative to the basis B. Since:

$$P^{-1} = \begin{bmatrix} \frac{1}{5} & \frac{2}{5} \\ -\frac{1}{5} & \frac{3}{5} \end{bmatrix}$$

we can check that:

$$\vec{v}_{B'} = \begin{bmatrix} \frac{1}{5} & \frac{2}{5} \\ -\frac{1}{5} & \frac{3}{5} \end{bmatrix} \begin{pmatrix} 4 \\ 3 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \end{pmatrix}$$

which is what we started with.

6.6.5 Eigenvalues and Eigenvectors

Definition (#6.6.262): An "eigenvalue" is by definition (we will find again this definition in the introduction to quantum algebra in the section of Wave Quantum Physics) a value λ belonging to a field $\mathbb{K}$ such that given a squared matrix $A\in M_{mm}(\mathbb{K})$ we have:

$$\exists\vec{X}\in M_{m1}(\mathbb{K})\quad \vec{X}\neq\vec{0}\text{ and }A\vec{X}=\lambda\vec{X} \tag{6.6.353}$$

and conversely a vector $\vec{X}\in M_{m1}(\mathbb{K})$ is an "eigenvector" if and only if:

$$\vec{X}\neq\vec{0},\exists\lambda\in\mathbb{K},A\vec{X}=\lambda\vec{X} \tag{6.6.354}$$

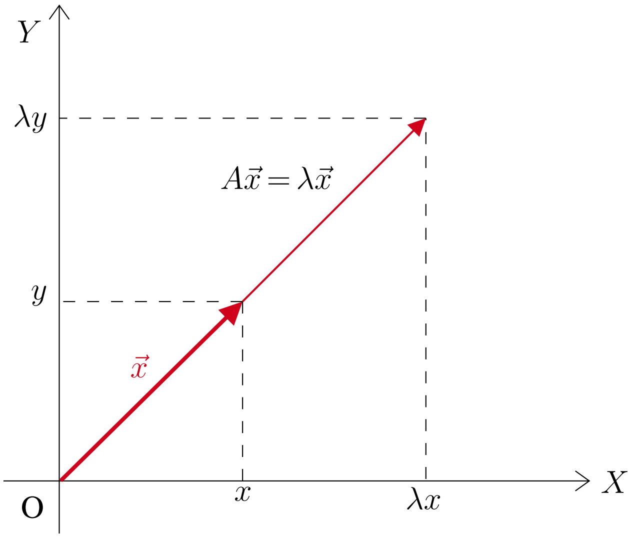


Figure 6.146: **Geometrical interpretation of eigenvector and eigenvalue in $\mathbb{R}^2$**

The major advantage of these concepts will be able the possibility to study a linear application, or any other item linked to a matrix representation, in a simple representation through a basis change on which the restriction of A is a single homothetic transformation (typically solving simple systems of differential equations).

Remark

This definition can be generalized to functional analysis (therefore it does not only applied to Matrix Algebra) too as by defining the "spectrum of an endomorphism" as the set:

$$\text{Sp}(f)=\{\lambda\in\mathbb{K},\exists x\in E\backslash\{0\}:f(x)=\lambda x\} \tag{6.6.355}$$

In other words: when a transformation (application of a matrix) acts on a vector, it modifies the direction of this vector except for certain particular matrices which have eigenvalues!

Thus, all the eigenvalues of a matrix $A\in M_{mm}(\mathbb{K})$ is named "spectrum of A" and satisfies the following homogeneous system named a "matrix-eigenvalue equation":

$$\boxed{(A-\lambda I_n)\vec{X}=\vec{0}} \tag{6.6.356}$$

or (whatever it is the same!):

$$(\lambda I_n - A)\vec{X} = \vec{0} \tag{6.6.357}$$

where I_n (also sometimes denoted by the symbol: $\mathbb{1}$) is for recall a diagonal unit matrix (and therefore also square) of dimension n. This system we know (proved above) has non-trivial solutions, therefore $\vec{X} \neq \vec{0}$ or $(\lambda I_n - A) \neq \vec{0}$, if and only if (we'll see many examples in various section related to physics in this textbook):

$$\det(A - \lambda I_n) = \begin{vmatrix} a_{11}-\lambda & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22}-\lambda & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn}-\lambda \end{vmatrix} = 0 \tag{6.6.358}$$

that is to say that the matrix $A - \lambda I_n$ is not invertible (singular).

The determinant $\det(A - \lambda I_n)$ is a polynomial on λ of degree n and can have at maximum n solutions/eigenvalues as we have proved it in our study of polynomials (see section Calculus page 1368) and is named "characteristic polynomial" of A and the equation $\det(A - \lambda I_n)$ is named "characteristic equation" of A or "eigenvalues equation".

For the small parenthesis, it is nice to notice that we always have in the development of $\det(A - \lambda I_n)$ the trace of the matrix $\text{tr}(A)$ and the determinant $\det(A)$ that appear. Let us see two examples of this:

✍**Examples:**

E1. Let us begin with the case $n = 2$:

$$\det(A - \lambda I_2) = \begin{vmatrix} a_{11}-\lambda & a_{12} \\ a_{21} & a_{22}-\lambda \end{vmatrix} = \lambda^2 - \underbrace{(a_{11}+a_{22})}_{\text{tr(A)}}\lambda + \underbrace{(a_{11}a_{22}-a_{21}a_{12})}_{\text{det(A)}} \tag{6.6.359}$$

Therefore for a square matrix of dimension 2, the eigenvalues are (simple resolution of a polynomial of the 2nd degree):

$$\begin{aligned} \lambda_1 &= \frac{a_{11}+a_{22}+\sqrt{(a_{11}-a_{22})^2+4(a_{11}a_{22}-a_{12}a_{21}}}{2} = \frac{\text{tr}(A)+\sqrt{(\text{tr}(A)^2+4\det(A)}}{2} \\ \lambda_2 &= \frac{a_{11}+a_{22}-\sqrt{(a_{11}-a_{22})^2+4a_{12}a_{21}}}{2} = \frac{\text{tr}(A)-\sqrt{\text{tr}(A)^2+4\det(A)}}{2} \end{aligned} \tag{6.6.360}$$

E2. For a matrix of dimension $n = 3$, we have:

$$\begin{aligned} \det(A - \lambda I_3) = \begin{vmatrix} a_{11}-\lambda & a_{22} & a_{13} \\ a_{21} & a_{22}-\lambda & a_{23} \\ a_{31} & a_{32} & a_{33}-\lambda \end{vmatrix} &= -\lambda^3 + \underbrace{(a_{11}+a_{22}+a_{33})}_{\text{tr(A)}}\lambda^2 \\ &- (a_{11}a_{33}+a_{22}a_{33}+a_{11}a_{22}-a_{32}a_{23}-a_{12}a_{21}-a_{31}a_{13})\lambda \\ &+ \underbrace{a_{11}a_{22}a_{33}-a_{11}a_{32}a_{23}-a_{12}a_{21}a_{33}+a_{31}a_{32}a_{12}+a_{13}a_{21}a_{32}-a_{13}a_{31}a_{22}}_{\det(A)} \end{aligned} \tag{6.6.361}$$

and here... the final solution (roots) are quite less easy in the general case...

On the path let us notice (we will generalize the result coming from this during our study of the spectral theorem) that as multiplying the homogeneous system:

$$(\lambda I_n - A)\vec{X} = \vec{0} \tag{6.6.362}$$

by -1 on the both sides of the equality doesn't change anything to the problem, then we get:

$$\begin{aligned}
&\det(A-\lambda I_2)=0 \Rightarrow\\
&\det(\lambda I_2 - A) = \begin{vmatrix} \lambda - a_{11} & -a_{12} \\ -a_{21} & \lambda - a_{22} \end{vmatrix} = (\lambda - a_{11})(\lambda - a_{22}) - (-a_{12})(-a_{21})\\
&= \lambda^2 - (a_{11}+a_{22})\lambda + a_{11}a_{22} - a_{12}a_{21} = \lambda^2 - \underbrace{(a_{11}+a_{22})}_{\text{tr}(A)}\lambda + (a_{11}a_{22}-a_{12}a_{21}) = 0
\end{aligned} \tag{6.6.363}$$

Since we know that the eigenvalues are solutions of each of the above polynomials, we then have:

$$\lambda^2 - \underbrace{(a_{11}-a_{22})}_{\text{tr}(A)}\lambda + (a_{11}a_{22} - a_{21}a_{12}) = 0 \Rightarrow (\lambda-\lambda_1)(\lambda-\lambda_2) = \lambda^2 - (\lambda_1+\lambda_2)\lambda + \lambda_1\lambda_2 = 0 \tag{6.6.364}$$

Thus by a term by term correspondence it comes the very important result in Statistics (and also in Numerical Methods!) that we will prove later in a more general way with the spectral theorem:

$$\boxed{\text{tr}(A) = \sum_i \lambda_i} \tag{6.6.365}$$

If we look at $(\lambda I_n - A)$ as a linear application f, as it is non-trivial solutions that interest us, we can say that the eigenvalues are the elements λ such that:

$$\ker(f) = \ker(\lambda I_n - A) \neq \{\vec{0}\} \tag{6.6.366}$$

and that the kernel constitutes the "eigenspace" of A of the eigenvalue λ from which non-null elements are the eigenvectors. This is in some textbooks denoted by:

$$E_\lambda = \ker(f - \lambda Id) = \{x \in E; f(x) = \lambda x\} \tag{6.6.367}$$

And by the way... the set of all eigenvectors is named the "spectrum" of f.

It corresponds to the study of the main axes, according to which the application behaves like an expansion (homothetic application) multiplying the vectors by the same constant. This homothetic ratio is then the "eigenvalue", the vectors to which it applies the "eigenvectors" are assembled in a "eigenspace".

Another way of looking at it:

- A vector is said to be an "eigenvector" by a linear application if it is not zero and if the application does only change its size (norm) without changing its direction.

- An "eigenvalue", associated to an "eigenvector", is the size modification factor (homothetic ratio), i.e. the number by which we must multiply the vector to get its image. This factor can be negative (reverse direction of the vector) or zero (vector transformed into a vector of zero length).

  We can say that therefore that the eigenvalue λ "scalar" the application A for the eigenvector $\vec{X}$.

- An "eigenspace" associated to an "eigenvalue" is the set of eigenvectors that have the same eigenvalue value and a zero vector. They suffer all from the multiplication by the same factor.

Remark

In mechanics, we study the eigenfrequencies and eigenmodes of oscillating systems (see section Wave Mechanics page 3492). In Functional Analysis, an eigenfunction is an eigenvector for a linear operator, that is to say a linear application acting on a space of function (see section Functional Analysis page 2170). In geometry and optics, we speak of eigendirections to take into account the curvature of the surfaces (see section Non-Euclidean Geometry page 2663). In graph theory, an eigenvalue is simply an eigenvector of the adjacency matrix of the graph (see section Graph Theory page 3026).

So as the determinant of $\det(A-\lambda I_n)$ is a polynomial on λ then the λ_i are also the roots of the characteristic polynomial:

$$\begin{aligned}\det(A-\lambda I-n)&=(-1)^n(\lambda-\lambda_1)(\lambda-\lambda_2)\ldots(\lambda-\lambda_n)\\&=(-1)(\lambda-\lambda_1)(-1)(\lambda-\lambda_2)\ldots(-1)(\lambda-\lambda_n)\\&=(\lambda_1-\lambda)(\lambda_2-\lambda)\ldots(\lambda_n-\lambda)\end{aligned}\tag{6.6.368}$$

Therefore:

$$\boxed{\det(A-\lambda I_n)=\prod_{i=1}^{n}(\lambda_i-\lambda)}\tag{6.6.369}$$

This is a relation used sometimes in some statistical models (for example the MANOVA!).

Before closing this short introduction to the eigenvalues and eigenvectors (we will discussed this further below), let us indicate that since an eigenvector must satisfy the homogeneous system:

$$(A-\lambda I_n)\vec{X}=\vec{0}\tag{6.6.370}$$

Nothing prevents us then from multiplying the eigenvector by a constant k which normalizes it to the unit (technique often used in statistics and numerical methods to improve the floating precision of the algorithms) since:

$$(A-\lambda I_n)k\vec{X}=(A-\lambda I_n)\vec{U}=k\cdot\vec{0}=\vec{0}\tag{6.6.371}$$

Thus in practice it is customary that if the eigenvector is given for example by:

$$\vec{x}=\begin{pmatrix}x\\y\\z\end{pmatrix}\tag{6.6.372}$$

To normalize it at the unit by writing:

$$\vec{U}=\frac{\vec{X}}{\|\vec{X}\|}=\begin{pmatrix}\dfrac{x}{\sqrt{x^2+y^2+z^2}}\\ \dfrac{y}{\sqrt{x^2+y^2+z^2}}\\ \dfrac{z}{\sqrt{x^2+y^2+z^2}}\end{pmatrix} \tag{6.6.373}$$

For the section of Wave Quantum Physics and more especially for the study of the angular momentum and spin we need to prove that given an operator acting on an eigenvector, then if we square the operator, this result in squaring the eigenvalue.

Proof 6.42.2. Given:

$$Ax=\lambda x \tag{6.6.374}$$

Then:

$$A^2x=A(Ax)=A(\lambda x)=\lambda(Ax)=\lambda(\lambda x)=\lambda^2x \tag{6.6.375}$$

■ Q.E.D.

6.6.5.1 Rotation Matrices and Eigenvalues

Now that we have seen what was an eigenvalue and an eigenvector, let us come back on a particular type of orthogonal matrices that we will be particularly useful to us in our study of quaternions (see section Numbers page 261), of groups and symmetries (see section Set Algebra page 1417) and particle physics (see section Elementary Particle Physics page 5194).

We denote, as what has been seen in the section of Set Algebra, $\text{O}(n)$ the set of $n\times n$ (square) orthogonal matrices with coefficients in $\mathbb{R}$, that is to say, satisfying:

$$A^TA=\mathbb{1} \tag{6.6.376}$$

That will denote also sometimes for recall sometimes as:

$$A^TA=I \tag{6.6.377}$$

The columns and rows of an orthogonal matrix the form the orthonormal basis of the usual space $\mathbb{R}^2$ for the usual dot product.

The determinant of an orthogonal matrix is equal to ±1 (rotation conserves angles and volumes), indeed $A^TA=I$ leads to:

$$\det(A^T)\det(A)=\det(A^TA)=\det(I)=1 \tag{6.6.378}$$

A rotation matrix with determinant $+1$ is a "proper rotation", and one with a negative determinant -1 is an "improper rotation", that is a reflection combined with a proper rotation.

✍**Example:**

Let us calculate now explicitly the determinant of a 2×2 rotation matrix (see section Numbers page 258) and 3×3 rotation matrix (see section Euclidean Geometry page 2648) as it is ask by many student on various Internet forums.

So first we consider the 2×2 rotation matrix and using the relation of the determinant proved earlier, we get:

$$\begin{aligned}\det(A)&=\begin{bmatrix}\cos(\alpha) & -\sin(\alpha)\\ \sin(\alpha) & \cos(\alpha)\end{bmatrix}\\ &=\cos(\alpha)\cos(\alpha)-(-\sin(\alpha)\sin(\alpha))=\cos^2(\alpha)+\sin^2(\alpha)=1\end{aligned} \tag{6.6.379}$$

And for one randomly chosen rotation matrix of the three 3×3 rotation matrices (see section Euclidean Geometry page 2648), we get:

$$\begin{aligned}\det(R_Z(\phi))&=\left|\begin{bmatrix}\cos(\phi) & \sin(\phi) & 0\\ -\sin(\phi) & \cos(\phi) & 0\\ 0 & 0 & 1\end{bmatrix}\right|\\ &=a_{11}a_{22}a_{33}-a_{11}a_{23}a_{32}-a_{12}a_{21}a_{33}+a_{12}a_{23}a_{31}+a_{13}a_{21}a_{32}-a_{13}a_{22}a_{31}\\ &=\cos(\phi)\cos(\phi)\cdot 1-\cos(\phi)\cdot 0\cdot 0-\sin(\phi)(-\sin(\phi))\cdot 1+\sin(\phi)\cdot 0\cdot 0\\ &+1\cdot(-\sin(\phi))\cdot 0-0\cdot 0\cos(\phi)\cdot 0\\ &=\cos(\phi)\cos(\phi)-\sin(\phi)(-\sin(\phi))=\cos^2(\phi)+\sin^2(\phi)=1\end{aligned} \tag{6.6.380}$$

We denote by $\text{SO}(n)$ the set of orthogonal matrices of determinant 1 (for more details see the section of Set Algebra page 1417). Let us show in three points that if $A\in\text{SO}(3,\mathbb{R})$ then A is the rotation matrix relative to an axis passing through the origin.

1. Any eigenvalue of a rotation matrix A (real or complex) is of module 1. In other words it conserve the norm:

   Indeed, if λ is an eigenvalue of eigenvector $\vec{X}$, we have:

   $$|\lambda|^2\|\vec{X}\|^2=\|A\vec{X}\|^2=\langle A\vec{X}|A\vec{X}\rangle=\langle\vec{X}|A^TA\vec{X}\rangle=\langle\vec{X}|\vec{X}\rangle=\|\vec{X}\|^2 \tag{6.6.381}$$

   or noting the dot product with the book usual notation:

   $$|\lambda|^2\|\vec{X}\|^2=\|A\vec{X}\|^2=A\vec{X}\circ A\vec{X}=\vec{X}\circ A^TA\vec{X}=\vec{X}\circ\vec{X}=\|\vec{X}\|^2 \tag{6.6.382}$$

2. It exists a straight line in the space that is used a rotation axes and any vector on this line is not modified by any rotation.

   Let us denote by $\vec{X}$ an eigenvector of eigenvalue 1 (that is to say such that $A\vec{X}=\vec{X}$). As the reader may have perhaps already understand it (read until the end please!), the straight line generated by $\vec{x}$ that we will denote by $\langle\vec{X}\rangle$ constitutes our rotation axes.

   Indeed, any vector $\langle\vec{X}\rangle$ is send on itself by the application A. In this case, the orthonormal space denoted by $\langle\vec{X}\rangle^{\perp}$ that is of dimension 2 is the perpendicular plane to the rotation axes.

3. Any vector perpendicular to the rotation axes remains, after rotation, perpendicular to this axes. In other words, $\langle\vec{X}\rangle$ is invariant through the application of A.

   Indeed, if $\vec{w}\in\langle\vec{x}\rangle$ the, $w=A^TAw=A^Tw$ and for all $\vec{y}\in\langle\vec{X}\rangle^{\perp}$:

   $$A\vec{y}\circ\vec{w}=\vec{y}\circ A^T\vec{w}=\vec{y}\circ\vec{w}=0 \qquad (6.6.383)$$

   that is to say $A\vec{y}\langle\vec{X}\rangle^{\perp}$. Therefore $\langle\vec{X}\rangle^{\perp}$ is invariant by A.

   Finally, the restriction of A to the space $\langle\vec{X}\rangle^{\perp}$ is a rotation!

✍**Example:**

Given $e^{\mathrm{i}\alpha}$ (see the section Numbers where the rotation by the complex number is proven) an eigenvalue (which module is 1 as we proved it during our study of complex numbers) of A restraint to $\langle\vec{X}\rangle^{\perp}$.

Let us write $\vec{w}=\vec{u}+\mathrm{i}\vec{v}$ an eigenvector with $\vec{u},\vec{v}\in\mathbb{R}^2$ such as:

$$A\vec{w}=e^{\mathrm{i}\alpha}\vec{w} \qquad (6.6.384)$$

with (as we already proved it in our study of complex numbers):

$$A=\begin{pmatrix}\cos(\alpha) & -\sin(\alpha)\\ \sin(\alpha) & \cos(\alpha)\end{pmatrix} \qquad (6.6.385)$$

where we know by our study of complex numbers, that the vectors $\vec{u},\vec{v}$ generate an orthogonal basis (not necessarily normalized at the unit!) of $\langle\vec{X}\rangle^{\perp}$.

Remark

We think that it could by easy at this level of the reader to check that this matrix is orthogonal (if it not the case contact us and this will be detailed!).

6.6.6 Spectral Theorem

Let us now see a very important theorem relatively to the eigenvalues and eigenvectors which is named the "spectral theorem" which will be very useful to us for the various sections of physics of this textbook and also the section Statistics as well as in the section of Numerical Methods and Industrial Engineering.

To summarize, mathematicians say in their language that the spectral theorem give the possibility to affirm the diagonalization of endomorphism[27] (of matrices) and also justify the decomposition in eigenvalues (also named "singular value decomposition" abbreviated S.V.D.) that we will see further below during our presentation of some matrices decomposition techniques.

Remark

The singular value decomposition theorem (S.V.D.) is however very general, in the sense that it applies to any rectangular matrices. The eigenvalue decomposition (see further below the details), however, only works for some square matrices.

To simplify the proof, we will deal here only real matrices (component in $\mathbb{R}$) and also avoiding up the language of mathematicians.

We will denote in a first time $M_n(\mathbb{R})$ the set of all $n \times n$ (square) matrices with real coefficients.

We will confuse the matrix $M \in M_n(\mathbb{R})$ with the linear application on the vector space $\mathbb{R}^n$ by:

$$\vec{v} \mapsto M\vec{v} \tag{6.6.386}$$

with $\vec{v} \in \mathbb{R}^n$.

Reminder: We have seen above during our study of basis changes that if $(\vec{c}_1, \ldots, \vec{c}_n)$ is a basis of $\mathbb{R}^n$ and $M \in M_n(\mathbb{R})$ then the matrix of the linear map M in the basis $(\vec{c}_1, \ldots, \vec{c}_n)$ is:

$$S^{-1}MS \tag{6.6.387}$$

where S is the matrix formed by the column vectors $\vec{c}_1, \ldots, \vec{c}_n$.

First, we simply check that if A is a symmetric matrix then (this should be trivial but it can be verified with an example of dimension 2 very quickly):

$$(A\vec{u}) \circ \vec{v} = \vec{u} \circ A^T\vec{v} = \vec{u} \circ A\vec{v} \tag{6.6.388}$$

We now propose to study the following properties of a symmetric matrix M:

P1. All eigenvalues of M are reals.

Proof 6.42.3. Given:

$$\vec{z} = \begin{pmatrix} z_1 \\ \vdots \\ z_n \end{pmatrix} \in \mathbb{C}^n \tag{6.6.389}$$

---

[27] What they also name an "endomorphism reduction"

an a priori complex eigenvector of the eigenvalue $\lambda \in \mathbb{C}$. Let us denote:

$$\vec{\bar{z}} = \begin{pmatrix} \bar{z}_1 \\ \vdots \\ \bar{z}_n \end{pmatrix} \tag{6.6.390}$$

the conjugate vector of $\vec{z}$. Then we have:

$$\vec{\bar{z}}^T M \vec{z} = \vec{\bar{z}}^T \lambda \vec{z} = \lambda \|\vec{z}\|^2 \tag{6.6.391}$$

On the other hand since $M = \overline{M}$ we have:

$$\vec{\bar{z}}^T M \vec{z} = \vec{\bar{z}}^T \overline{M} \vec{z} = \overline{\vec{z}^T M \vec{z}} = \overline{(M\vec{z})^T} \vec{z} = \overline{\lambda \vec{z}^T} \vec{z} = \bar{\lambda} \|\vec{z}\|^2 \tag{6.6.392}$$

As $\vec{z} \neq \vec{0}$, we have $\lambda = \vec{\lambda}$ and therefore, $\lambda \in \mathbb{R}$.

■ Q.E.D.

P2. Two eigenspaces of M relative to different eigenvalues are orthogonal (in other words, the eigenvectors are independent).

Proof 6.42.4. Let λ, μ be two distinct eigenvalues of corresponding eigenvectors $\vec{u}, \vec{v}$. We have (don't forget that M is symmetric!):

$$\lambda(\vec{u} \circ \vec{v}) = (\lambda \vec{u}) \circ \vec{v} = (M\vec{u}) \circ \vec{v} = \vec{u} \circ (M\vec{v}) = \vec{u} \circ (\mu \vec{v}) = \mu(\vec{u} \circ \vec{v}) \tag{6.6.393}$$

therefore:

$$(\lambda - \mu) \cdot (\vec{u} \circ \vec{v}) = 0 \tag{6.6.394}$$

which leads to:

$$(\vec{u} \circ \vec{v}) = 0 \tag{6.6.395}$$

■ Q.E.D.

Before going further, we also have to prove that if $M \in M_n(\mathbb{R})$ is a symmetrical matrix and V and vectorial subspace of $\mathbb{R}^n$ invariant relatively to M (that is to say that satisfies for any $\vec{v} \in V : M\vec{v} \in V$) then we have the following properties:

P3. The orthogonal of V denoted obviously by $V^\perp$ (obtained by applying the Gram-Schmidt method seen in the section of Vector Calculus page 2062) is also invariant through M.

Proof 6.42.5. Given $\vec{v} \in V$ and $\vec{w} \in V^\perp$ then:

$$(M\vec{w}) \circ \vec{v} = \vec{w} \circ \left(\underbrace{M\vec{v}}_{\in V} \right) = 0 \tag{6.6.396}$$

this shows well that $M\vec{w} \in V^\perp$.

■ Q.E.D.

P4. If $(\vec{w}_1,\ldots,\vec{w}_k)$ is an orthonormal basis of $\vec{V}^{\perp}$ then the restriction matrix of M to $V^{\perp}$ in the basis $(\vec{w}_1,\ldots,\vec{w}_k)$ is also symmetrical.

Proof 6.42.6. Let us denote $A=(a_{ij})_{1\leq i,j\leq k}$ the matrix of the restriction of M to $V^{\perp}$ in the basis $(\vec{w}_1,\ldots,\vec{w}_k)$. We have by definition for any $j=1\ldots k$ (as the vector resulting of a linear application such as M can be express in its basis):

$$M\vec{w}_j=\sum_{i=1}^{k}a_{ij}\vec{w}_i \tag{6.6.397}$$

Or:

$$(M\vec{w}_j)\circ\vec{w}_m=\left(\sum_{i=1}^{k}a_{ij}\vec{w}_i\right)\circ\vec{w}_m=\sum_{i=1}^{k}a_{ij}(\vec{w}_i\circ\vec{w}_m)=a_{mj} \tag{6.6.398}$$

as:

$$\vec{w}_i\circ\vec{w}_m=0 \tag{6.6.399}$$

if $i\neq m$ in the orthonormal basis.

On another side:

$$(M\vec{w}_j)\circ\vec{w}_m=\vec{w}_j\circ(M\vec{w}_m)=\vec{w}_j\circ\left(\sum_{i=1}^{k}a_{im}\vec{w}_i\right)=\sum_{i=1}^{k}a_{im}(\vec{w}_j\circ\vec{w}_i)=a_{jm} \tag{6.6.400}$$

Therefore:

$$a_{mj}=a_{jm} \tag{6.6.401}$$

This shows that:

$$A=A^T \tag{6.6.402}$$

■ Q.E.D.

Theorem 6.43. We will now be able to show that any symmetric matrix $M\in M_n(\mathbb{R})$ is diagonalizable. That is to say that there is an invertible matrix S such that the result of the calculation:

$$S^{-1}MS \tag{6.6.403}$$

gives a diagonal matrix!

Remark

In fact we will see, to be more precise, that there exists an orthogonal matrix S such that $S^{-1}MS$ is diagonal.

Reminder: Say that S is "orthogonal" means that $SS^T=I$ (where I is the identity matrix) which is equivalent to say that the columns of S form an orthonormal basis of $\mathbb{R}^n$.

Proof 6.43.1. We prove the assertion by induction on n. If $n=1$ there is nothing to prove. Let us suppose that the assertion is satisfied for $k\leq n$ and let us prove it for $k=n+1$. Then given $M\in M_{n+1}(\mathbb{R})$ a symmetric matrix and λ an eigenvalue of M.

We easily verify that the eigenspace:

$$W=\text{ker}(\lambda I_{n+1}-M) \tag{6.6.404}$$

is invariant by M (just take any numerical application) and that by the proof seen earlier, that $W^{\perp}$ is also invariant by M. Moreover, we know (see section Vector Calculus page 1814) that $\mathbb{R}^{n+1}$ can be decomposed into a direct sum:

$$\mathbb{R}^{n+1}=W\oplus W^{\perp} \tag{6.6.405}$$

If:

$$\dim(W^{\perp})=0 \tag{6.6.406}$$

then:

$$\mathbb{R}^{n+1}=W \tag{6.6.407}$$

and it is sufficient to take an orthonormal basis of W to diagonalise M. Indeed, if $(\vec{w}_1,\ldots,\vec{w}_{n+1})$ is such a basis, the matrix S formed by the column vectors $\vec{w}_j$ $(j=1\ldots n+1)$ is orthogonal and satisfies:

$$S^{-1}MS=S^{-1}\lambda S=\lambda I_{n+1} \tag{6.6.408}$$

and $S^{-1}MS$ is indeed diagonal.

Let us now suppose that $\dim(W^{\perp})>0$ and given $(\vec{u}_1,\ldots,\vec{u}_m)$ with $m\leq n$ an orthonormal basis of $W^{\perp}$. Let us denote by A the restriction matrix of M to $W^{\perp}$ in the basis $(\vec{u}_1,\ldots,\vec{u}_m)$. A is also symmetric (as proved in one of the preceding properties).

By induction hypothesis there exists an orthogonal matrix $H\in M_m(\mathbb{R})$ such that $H^{-1}AH$ is diagonal.

Let us denote by $(\vec{w}_1,\ldots,\vec{w}_{n+1-m})$ an orthonormal basis of W and G the matrix formed by the column vectors: $\vec{w}_1,\ldots,\vec{w}_{n+1-m},\vec{u}_1,\ldots\vec{u}_m$. So we can write that:

$$G^{-1}MG=\begin{bmatrix}\lambda I_{n+1-m} & 0\\ 0 & A\end{bmatrix} \tag{6.6.409}$$

and G is also orthogonal by construction.

Let us consider the following block matrix (matrix of matrices):

$$L=\begin{bmatrix}I_{n+1-m} & 0\\ 0 & H\end{bmatrix}\in M_{n+1}(\mathbb{R}) \tag{6.6.410}$$

and let us put:

$$S=GL \tag{6.6.411}$$

It is almost obvious that S is orthogonal as G and L are also orthogonal. Indeed, if:

$$GG^T = I \qquad \text{and} \qquad LL^T = I \tag{6.6.412}$$

then (remember that matrix multiplication is associative !!!):

$$(GL)(GL)^T = (GL)(L^TG^T) = G(LL^T)G^T = GIG^T = GG^T = I \tag{6.6.413}$$

Also S satisfies:

$$\begin{aligned}S^{-1}MS &= L^{-1}(G^{-1}MG)L\\ &= \begin{bmatrix} I_{n+1-m} & 0 \\ 0 & H \end{bmatrix}^{-1} \cdot \begin{bmatrix} \lambda I_{n+1-m} & 0 \\ 0 & A \end{bmatrix} \cdot \begin{bmatrix} I_{n+1-m} & 0 \\ 0 & H \end{bmatrix} = \begin{bmatrix} \lambda I_{n+1-m} & 0 \\ 0 & H^{-1}AH \end{bmatrix}\end{aligned} \tag{6.6.414}$$

and then:

$$\begin{bmatrix} \lambda I_{n+1-m} & 0 \\ 0 & H^{-1}AH \end{bmatrix} \tag{6.6.415}$$

is indeed diagonal.

■ Q.E.D.

Finally here is finally the famous "spectral theorem" (real case):

Theorem 6.44. Given $M \in M_n(\mathbb{R})$ a symmetric matrix, then there exists an orthonormal basis made of eigenvectors of M.

Proof 6.44.1. So we have seen in the preceding paragraphs that there exists an orthogonal matrix S such that $S^{-1}MS$ is diagonal if M is symmetric! Let denote by $\vec{c}_1, \ldots, \vec{c}_n$ the columns of S. The basis $(\vec{c}_1, \ldots, \vec{c}_n)$ is an orthonormal basis of $\mathbb{R}^2$ as S is orthogonal. Denoting the $\vec{e}_i$ the i-th vector of the canonical basis of $\mathbb{R}^n$ and λ_i and the i-th diagonal coefficient of S^1MS we have without directly supposing that λ_i is an eigenvalue for now:

$$\lambda_i\vec{e}_i = (S^{-1}MS)\vec{e}_i = S^{-1}M\vec{c}_i \tag{6.6.416}$$

by multiplying by S on both sides of the equality we have:

$$\lambda_i S\vec{e}_i = M\vec{c}_i \tag{6.6.417}$$

and therefore:

$$\lambda_i\vec{c}_i = M\vec{c}_i \tag{6.6.418}$$

which shows that $\vec{c}_1, \ldots, \vec{c}_n$ are eigenvectors and λ_i the corresponding eigenvalues.

■ Q.E.D.

To finish about the spectral theorem in this textbook, let us so reprove a result we get earlier but that was presented in a quite ugly way and poorly rigorous (the sum of the eigenvalues equals the trace of a matrix):

$$\text{tr}(A)=\sum_i \lambda_i \tag{6.6.419}$$

Remember that spectral theorem therefore tells us that for any symmetric matrix M, there exists an orthogonal matrix S such that:

$$S^{-1}MS \tag{6.6.420}$$

is diagonal. Nothing prevents us to choose the resulting diagonal matrix as a matrix of eigenvalues in the diagonal. What we denote usually:

$$\Lambda=S^{-1}MS \tag{6.6.421}$$

and as S is a real orthogonal matrix and that by definition we have that a matrix is orthogonal if and only if $A^{-1}=A^T$, then we find the following relation:

$$\boxed{\Lambda=S^TMS} \tag{6.6.422}$$

Commonly named a "spectral decomposition" or "eigendecomposition".

So obviously we will have to find S if M is known or vice versa. Anyway, let us come back on our topic and take track of this relation:

$$\text{tr}(\Lambda)=\sum_i \lambda_i=\text{tr}(S^{-1}MS) \tag{6.6.423}$$

Then by using the property of the trace tr, of the associativity of the matrix multiplication, and the orthogonality of S we have:

$$\sum_{i=1}^n \lambda_i=\text{tr}\left((S^{-1}M)S\right)=\text{tr}\left(S(S^{-1}M)\right)=\text{tr}\left((SS^{-1})M\right)=\text{tr}(I_nM)=\text{tr}(M) \tag{6.6.424}$$

This reprove the results seen earlier above with a condition that was not trivial at this time: the matrix must be symmetrical (or symmetrizable)!

We also have by extension:

$$M=S\Lambda S^{-1} \tag{6.6.425}$$

and therefore by using the proven property relatively to the determinant (during our proofs of the main determinant properties) and the conjugated matrices we get:

$$\det(M)=\det(\Lambda S^{-1})=\det(S)\det(\Lambda)\det(S^{-1})=\det(S)\det(\Lambda)\det(S)^{-1}=\det(\Lambda) \tag{6.6.426}$$

and therefore if M is symmetric we have the important property:

$$\boxed{\det(M)=\det(\Lambda)=\prod \lambda_i} \tag{6.6.427}$$

Remark

This result is in this text a particular form of the more general case (thus also applicable to rectangular or also non-orthogonal matrices) and that seems to be named the "Eckart-Young theorem".

✍**Example:**

We want to show that:

$$M=\begin{bmatrix}1 & 3\\ 3 & 1\end{bmatrix} \tag{6.6.428}$$

we assume that we know that the eigenvalue-eigenvector pairs are:

$$\lambda_1=4 \qquad \vec{v}_1=\begin{pmatrix}1\\ 1\end{pmatrix} \qquad \text{and} \qquad \lambda_2=-2 \qquad \vec{v}_2=\begin{pmatrix}-1\\ 1\end{pmatrix} \tag{6.6.429}$$

We therefore introduce S and Λ as follows:

$$S=[\vec{v}_1,\vec{v}_2]=\begin{bmatrix}1 & -1\\ 1 & 1\end{bmatrix}\Rightarrow S^{-1}=\frac{1}{2}\begin{bmatrix}1 & 1\\ -1 & 1\end{bmatrix} \qquad \Lambda=\begin{bmatrix}\lambda_1 & 0\\ 0 & \lambda_2\end{bmatrix}=\begin{bmatrix}4 & 0\\ 0 & -2\end{bmatrix} \tag{6.6.430}$$

We must show that $M=S\Lambda S^{-1}$. This is indeed the case, since:

$$S\Lambda S^{-1}=\begin{bmatrix}1 & -1\\ 1 & 1\end{bmatrix}\begin{bmatrix}4 & 0\\ 0 & -2\end{bmatrix}\frac{1}{2}\begin{bmatrix}1 & 1\\ -1 & 1\end{bmatrix}=\begin{bmatrix}4 & 2\\ 4 & -2\end{bmatrix}\frac{1}{2}\begin{bmatrix}1 & 1\\ -1 & 1\end{bmatrix}=\begin{bmatrix}2 & 1\\ 2 & -1\end{bmatrix}\begin{bmatrix}1 & 1\\ -1 & 1\end{bmatrix}=\begin{bmatrix}1 & 3\\ 3 & 1\end{bmatrix}=M \tag{6.6.431}$$

Therefore M is indeed diagonalizable.

6.6.7 Matrix Decompositions

In the mathematical discipline of linear algebra, a "matrix decomposition" or "matrix factorization" is a factorization of a matrix into a product of matrices in the purpose to simplify problems (typically to simplify the resolution of linear systems especially when the matrix to invert are huge!) or to make emerge some interesting properties in various cases.

There are many different matrix decompositions. Each finds use among a particular class of problems. There is almost two dozens of matrix decomposition techniques as far as we know. However in the texts that will follow below we will focus only on techniques that are used for practical explicit applications in this textbook (mainly in the field of Statistics and by extensions in financial engineering and also Machine Learning).

6.6.7.1 Singular Value Decomposition (SVD)

The singular value decomposition of a matrix M $(m\times n)$ is the factorization of M into the product of three matrices:

$$M=UDV^T \tag{6.6.432}$$

where the columns of U $(m\times r)$ and V $(r\times n)$ are orthonormal such that[28]:

$$\begin{gathered}\sum_{i=1}^{m}U_{ik}U_{ij}=\delta_{kj}\\ \sum_{i=1}^{r}V_{ik}V_{ij}=\delta_{kj}\end{gathered} \tag{6.6.433}$$

and the matrix D $(r\times r)$ is diagonal with positive real entries (r is the rank of M, i.e. $K\leq\min\{m,n\}$).

Remark

If V is orthogonal, then as we have seen at page 1954, we have $V^{-1}=V^T$, then that latter relation can also be written:

$$M=UDV^{-1} \tag{6.6.434}$$

The SVD is useful in many tasks as Data Mining, Image Processing and Advanced Numerical Methods.

To gain insight into the SVD, we treat the rows of an $m\times n$ matrix M as m points in a n-dimensional space and consider the problem of finding the best k-dimensional subspace with respect to the set of points. Here "best" means minimize the sum of the squares of the perpendicular distances of the points to the subspace.

---

[28] In other words, U and V are rotation matrices such that $U^TU=\mathbb{1}_{m\times m}$ and $V^TV=\mathbb{1}_{r\times r}$.

Let us begin with a special case of the problem where the subspace is 1-dimensional: a line through the origin. We will see later that the best-fitting k-dimensional subspace can be found by k applications of the best fitting line algorithm. Finding the best fitting line through the origin with respect to a set of points $\{x_i|1 \leq i \leq m\}$ in the plane means minimizing the sum of the squared distances of the points to the line. Here distance is measured perpendicular to the line. The problem is then named as we know: the "best least squares fit" (see section Numerical Methods page 6324).

Consider projecting a point $\vec{x}_1$ onto a line through the origin:

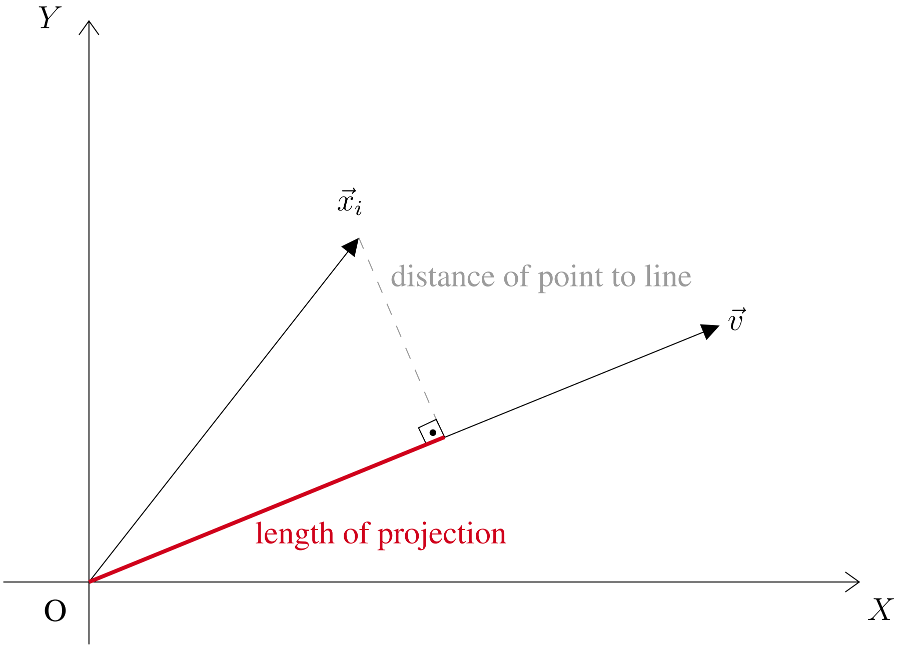

Figure 6.147: The projection of the point $\vec{x}_i$ onto the line through the origin in the direction of $\vec{v}$

Then using Pythagorean theorem we get:

$$\sqrt{x_{i1}^2+x_{i2}^2+\ldots+x_{in}^2}^{\,2} = (\text{lenght of projection})^2 + (\text{distance of point to line})^2 \tag{6.6.435}$$

That is:

$$x_{i1}^2+x_{i2}^2+\ldots+x_{in}^2 = (\text{lenght of projection})^2 + (\text{distance of point to line})^2 \tag{6.6.436}$$

Therefore (see figure):

$$(\text{distance of point to line})^2 = x_{i1}^2+x_{i2}^2+\ldots+x_{in}^2 - (\text{lenght of projection})^2 \tag{6.6.437}$$

To minimize the sum of squares for the distance to the line, one could minimize:

$$\sum_{i=1}^{m}(x_{i1}^2+x_{i2}^2+\ldots+x_{in}^2) \tag{6.6.438}$$

minus the sum of the square of the lengths of the projections of the points to the line. However, $\sum_{i=1}^{m}(x_{i1}^2+x_{i2}^2+\ldots+x_{in}^2)$ is constant! (independent of the line), so minimizing the sum of the squares of the distances is equivalent to maximizing the sum of the squares of the lengths of the projections onto the line. Similarly for best-fit subspaces, we could maximize the sum of the squared lengths of the projections onto the subspace instead of minimizing the sum of squared distances to the subspace.

6.6.7.1.1 Singular Vectors and Values

We will now build the "singular vectors" (and also "singular values") of a $m \times n$ matrix M.

Consider the rows of M as m points in a d-dimensional space. Consider the best fit line through the origin. Let $\vec{v}$ be a unit vector along this line.

The length of the projection of $\vec{x}_i$, the i-th row M, onto $\vec{v}$ is (see section Vector Calculus page 1821):

$$\|\text{proj}_v \vec{x}_i\| \tag{6.6.439}$$

That we will denote for what follows as (see section Vector Calculus page 1821):

$$|\vec{x}_i \circ \vec{v}| = \|\text{proj}_v \vec{x}_i\| \tag{6.6.440}$$

So in our case:

$$x_{i1}^2 + x_{i2}^2 + \ldots + x_{in}^2 = |\vec{x}_i \circ \vec{v}| \tag{6.6.441}$$

From this we denote the sum of all lengths of the projections by:

$$\|\text{proj}_v M\| = \|M\vec{v}\|^2 \tag{6.6.442}$$

The best fit line is the on maximizing $\|M\vec{v}\|^2$ (i.e.: $\|M\vec{v}\|$) and hence minimizing the sum of the squared distances of the points to the line.

With this in mind, we define the "first singular vector $\vec{v}_1$", of M, which is a vector, as the best fit through the origin for the m points in n-space that are the rows of M. Thus:

$$\vec{v}_1 = \max_{\|\vec{v}\|=1} \|M\vec{v}\| \tag{6.6.443}$$

The scalar value:

$$\sigma_1(M) = \|M\vec{v}_1\| \tag{6.6.444}$$

is named the "first singular value" of M. Notice that σ_1^2 is therefore implicitly the sum of the squares of the projections of the points to the line determined by $\vec{v}_1$.

The greedy approach to find this time not the best fit 1-dimensions but 2-dimensional subspace for a matrix M, takes $\vec{v}_1$ as the first basis vector for the 2-dimensional subspace and finds the best 2-dimensional subspace containing $\vec{v}_2$.

Thus, instead of looking for the best 2-dimensional subspace containing $\vec{v}_1$, look for a unit vector, denoted $\vec{v}_2$, perpendicular to $\vec{v}_1$ that maximizes $\|M\vec{v}\|^2$ among all such unit vectors.

Using the same strategy to find the best three and higher dimensional subspaces, defines $\vec{v}_3, \vec{v}_4, \ldots$ in similar manner.

The "second singular vector $\vec{v}_2$", is defined by the best fit line perpendicular to $\vec{v}_1$:

$$\vec{v}_2 = \max_{\vec{v} \perp \vec{v}_1, \|\vec{v}\|=1} \|M\vec{v}\| \tag{6.6.445}$$

The value:

$$\sigma_2(M)=\|M\vec{v}_2\| \tag{6.6.446}$$

is named the "second singular value" of M.

The "third singular vector $\vec{v}_3$" is defined similarly by:

$$\vec{v}_3=\max_{\vec{v}\perp\vec{v}_1,\vec{v}_2,\|\vec{v}\|=1}\|M\vec{v}\| \tag{6.6.447}$$

and so on...

The process stop theoretically when we have found $\vec{v}_1,\vec{v}_2,\ldots,\vec{v}_r$ as singular vector that satisfies:

$$\vec{v}_r=\max_{\vec{v}\perp\vec{v}_1,\ldots,\vec{v}_r,\|\vec{v}\|=1}\|M\vec{v}\| \tag{6.6.448}$$

As the $\vec{v}_i$ are perpendiculars, if we apply M on all this vectors, the resulting vectors will also be perpendicular between them!

Therefore we build the vectors:

$$\vec{u}_i=\frac{1}{\sigma_i(M)}M\vec{v}_i \tag{6.6.449}$$

that are all perpendiculars vectors between them as already mentioned and named "left singular vectors" of M when the $\vec{v}_i$ will be named "right singular vectors". The SVD theorem will fully explain the reason for these terms.

Theorem 6.45. Let M be an $m\times n$ matrix with right singular vector $\vec{v}_1,\ldots,\vec{v}_r$, left singular vectors $\vec{u}_1,\ldots,\vec{u}_r$, and corresponding singular values $\sigma_1,\ldots,\sigma_n$. Then the "singular value decomposition theorem" states that:

$$\boxed{M=\sum_{i=1}^{r}\sigma_i\vec{u}_i\vec{v}_i^T} \tag{6.6.450}$$

Proof 6.45.1. We start naturally from:

$$\sum_{i=1}^{r}\sigma_i\vec{u}_i\vec{v}_i^T=\sum_{i=1}^{r}\sigma_i\left(\frac{1}{\sigma_i}M\vec{v}_i\right)\vec{v}_i^T=\sum_{i=1}^{r}M\vec{v}_i\vec{v}_i^T=M\sum_{i=1}^{r}\vec{v}_i\vec{v}_i^T \tag{6.6.451}$$

Remark

Don't forget that $\vec{x}^T\vec{x}$ in Linear Algebra gives a scalar that is equivalent to the "dot product" ("inner product"), when instead $\vec{x}\vec{x}^T$ gives a square matrix named the "outer product", or sometimes "Gram matrix", defined by:

$$\vec{u}\vec{v}^T=\begin{pmatrix}u_1\\u_2\\u_3\\u_4\end{pmatrix}\begin{pmatrix}v_1 & v_2 & v_3\end{pmatrix}=\begin{bmatrix}u_1v_1 & u_1v_2 & u_1v_3\\u_2v_1 & u_2v_2 & u_2v_3\\u_3v_1 & u_3v_2 & u_3v_3\\u_4v_1 & u_4v_2 & u_4v_3\end{bmatrix} \tag{6.6.452}$$

Now let us consider a special case with (as I don't like the general proof):

$$\vec{v}_1 = \begin{pmatrix} v_{11} \\ v_{21} \\ v_{31} \end{pmatrix} \qquad \vec{v}_2 = \begin{pmatrix} v_{12} \\ v_{22} \\ v_{32} \end{pmatrix} \qquad \vec{v}_3 = \begin{pmatrix} v_{13} \\ v_{23} \\ v_{33} \end{pmatrix} \tag{6.6.453}$$

That gives:

$$\begin{aligned}\sum_{i=1}^{3} \vec{v}_i \vec{v}_i^T &= \begin{bmatrix} v_{11}^2 & v_{11}v_{21} & v_{11}v_{31} \\ v_{21}v_{11} & v_{21}^2 & v_{21}v_{31} \\ v_{31}v_{11} & v_{31}v_{21} & v_{31}^2 \end{bmatrix} + \begin{bmatrix} v_{12}^2 & v_{12}v_{22} & v_{12}v_{32} \\ v_{22}v_{12} & v_{22}^2 & v_{22}v_{32} \\ v_{32}v_{12} & v_{32}v_{22} & v_{32}^2 \end{bmatrix} + \begin{bmatrix} v_{13}^2 & v_{13}v_{23} & v_{13}v_{33} \\ v_{23}v_{13} & v_{23}^2 & v_{23}v_{33} \\ v_{33}v_{13} & v_{33}v_{23} & v_{33}^2 \end{bmatrix} \\ &= \begin{bmatrix} v_{11}^2+v_{12}^2+v_{13}^2 & v_{11}v_{21}+v_{12}v_{22}+v_{13}v_{23} & v_{11}v_{31}+v_{12}v_{32}+v_{13}v_{33} \\ v_{21}v_{11}+v_{22}v_{12}+v_{23}v_{13} & v_{21}^2+v_{22}^2+v_{23}^2 & v_{21}v_{31}+v_{22}v_{32}+v_{23}v_{33} \\ v_{31}v_{11}+v_{32}v_{12}+v_{33}v_{13} & v_{31}v_{21}+v_{32}v_{22}+v_{33}v_{23} & v_{31}^2+v_{32}^2+v_{33}^2 \end{bmatrix}\end{aligned} \tag{6.6.454}$$

So if we look closely the result is the same as if we define the matrix:

$$V = [\vec{v}_1, \vec{v}_2, \vec{v}_3] = \begin{bmatrix} v_{11} & v_{12} & v_{13} \\ v_{21} & v_{22} & v_{23} \\ v_{31} & v_{32} & v_{33} \end{bmatrix} \tag{6.6.455}$$

Therefore we can see that:

$$VV^T = \begin{bmatrix} v_{11} & v_{12} & v_{13} \\ v_{21} & v_{22} & v_{23} \\ v_{31} & v_{32} & v_{33} \end{bmatrix} \begin{bmatrix} v_{11} & v_{21} & v_{31} \\ v_{12} & v_{22} & v_{32} \\ v_{13} & v_{23} & v_{33} \end{bmatrix} \tag{6.6.456}$$

leads to the same result. Therefore we can write:

$$\sum_{i=1}^{r} \sigma_i \vec{u}_i \vec{v}_i^T = M \sum_{i=1}^{r} \vec{v}_i \vec{v}_i^T = M(VV^T) \tag{6.6.457}$$

But we must not forget that if V is an orthogonal matrix, then it represents an orthonormal basis and then we have proved already earlier above that in this case:

$$V^T V = VV^T = \mathbb{1} = [\delta_{ij}] \tag{6.6.458}$$

Therefore:

$$\sum_{i=1}^{r} \sigma_i \vec{u}_i \vec{v}_i^T = M(VV^T) = M\mathbb{1} = M \tag{6.6.459}$$

And this finish the proof!

■ Q.E.D.

The reader should also notice that:

$$M = \sum_{i=1}^{r} \sigma_i \vec{u}_i \vec{v}_i^T \tag{6.6.460}$$

and:

$$\boxed{\underset{(m\times n)}{M}=\underset{(m\times r)}{U}\underset{(r\times r)}{D}\underset{(r\times n)}{V^T}} \tag{6.6.461}$$

also often denoted $M=U\Sigma V^T$ (as Σ is the upper case letter of σ), are equivalent notation for the same thing (just develop the last one explicitly and you will see you fall back on the same result[29])! The difference is that the notation with the sum is most used in Data Mining and that with the matrices in Statistics.

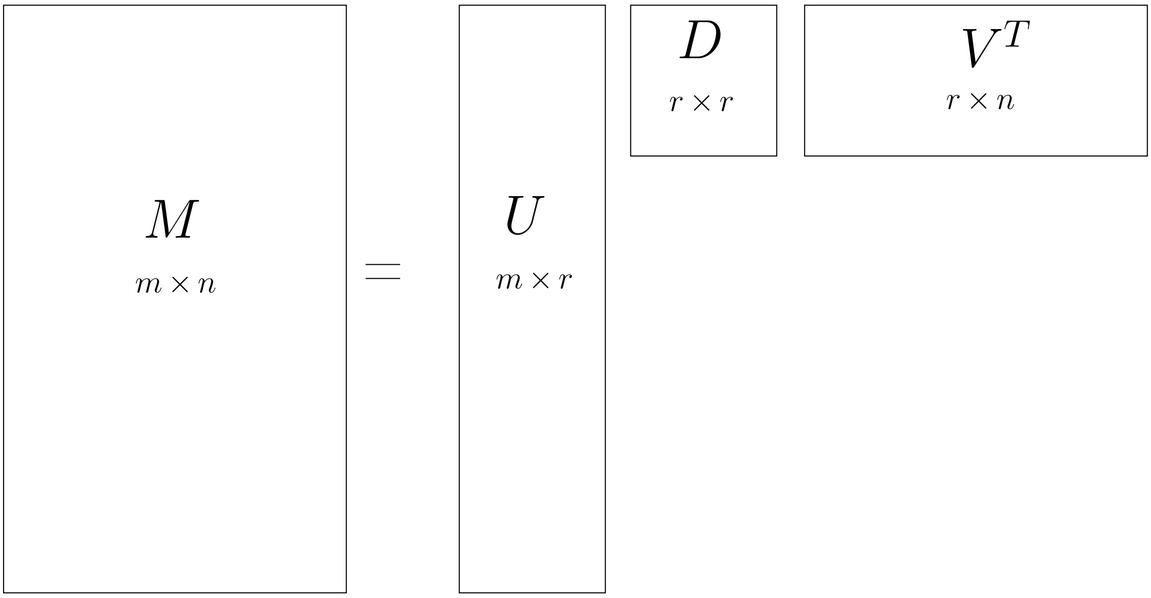

Figure 6.148: SVD decomposition of a $m\times n$ matrix

It is usage to build the matrix D such that the diagonal is in descending order of amplitude and to order the vectors $\vec{v}_i$ in the corresponding order. The reason is quite easy to understand as you can see in the example further below.

This is important to know that this not the only possible decomposition of a matrix. The are many other one but we will focus in this textbook only the decomposition that are directly useful for engineering topics presented in this textbook.

Remark

Some authors prefers to work with the norm of the singular values, that is, with $\sqrt{\sigma_i}$, therefore the left singular value are defined as:

$$\vec{u}_i=\frac{1}{\sqrt{\sigma_i}}M\vec{v}_i \tag{6.6.462}$$

Without that it changes our previous proof result that will just be:

$$M=\sum_{i=1}^{r}\sqrt{\sigma_i}\vec{u}_i\vec{v}^T \tag{6.6.463}$$

---

[29] On request we can write the details

That in Europe is frequently written (but can bring to confusion with the notation of eigenvalues...):

$$M = \sum_{i=1}^{r} \sqrt{\lambda_i} \vec{u}_i \vec{v}^T \quad (6.6.464)$$

or in matrix form (...):

$$M = U\Lambda^{1/2}V^T \quad (6.6.465)$$

Let us take a practical example in image processing of SVD (made by Jason Liu in MATLAB®). The image below is an image made of 400 unique row vectors (the reader can find the equivalent example in our `R` companion book):

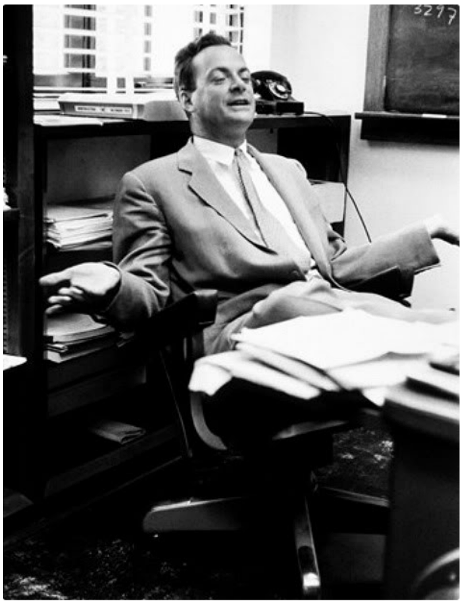

Figure 6.149: SVD in MATLAB® example original image

What happens if in the sum:

$$M = \sum_{i=1}^{r} \sqrt{\sigma_i} \vec{u}_i \vec{v}^T \quad (6.6.466)$$

we take only the first biggest singular vector?:

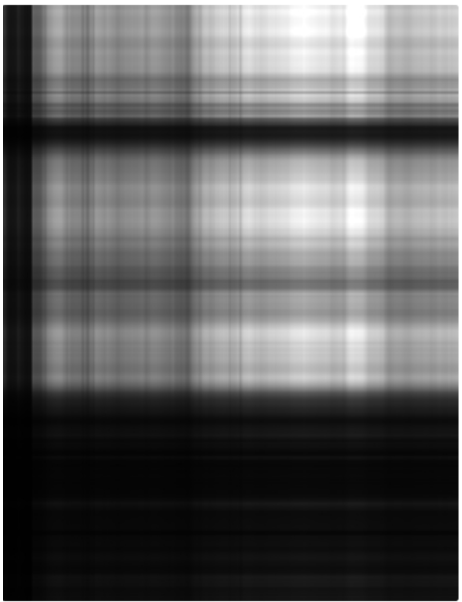

Figure 6.150: **MATLAB® SVD with $r=1$**

What happens if we take the first two singular vectors?:

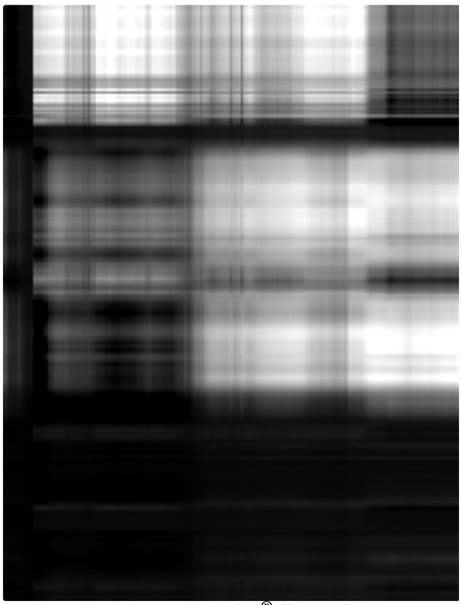

Figure 6.151: **MATLAB® SVD with $r=2$**

...and if we take the first ten singular vectors?:

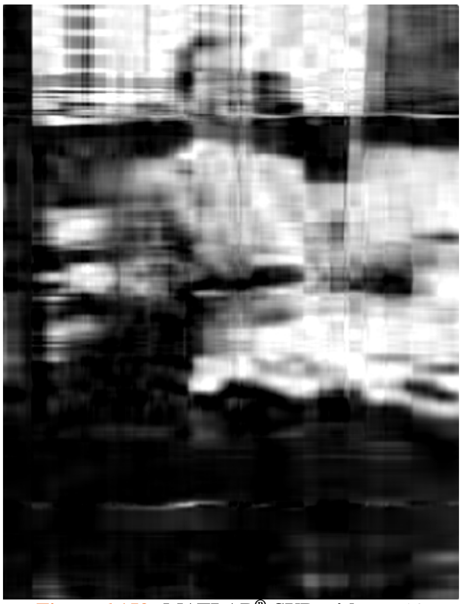

Figure 6.152: **MATLAB® SVD with** $r=10$

...and if we take the first fifty singular vectors?:

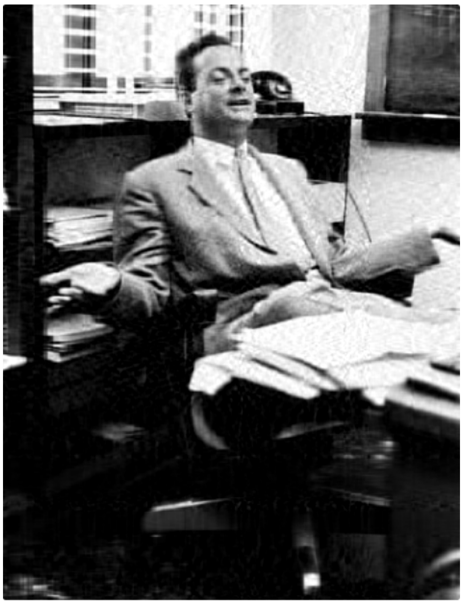

Figure 6.153: **MATLAB® SVD with** $r=50$

There we have it! Using 50 singular vectors we get a decent representation of what 400 vectors look like.

So as we can see SVD is a great space reduction technique!

Remark

Let $U\Sigma V^T$ be the singular value decomposition of a matrix A. Then U is an $m\times m$ unitary matrix (i.e. $U^TU=I$), Σ is a diagonal $m\times n$ matrix ($\Sigma_{ii}=\sigma_i(A)$), and V is an

$n\times n$ unitary matrix (i.e. $V^TV=I$). Using the Frobenius norm (see page 1623) we have:

$$\begin{aligned}\|A\|_F^2&=\text{tr}\left(A^TA\right)=\text{tr}\left(\left(U\Sigma V^T\right)^T U\Sigma V^T\right)=\text{tr}\left(V\Sigma^TU^TU\Sigma V^T\right)\\&=\text{tr}\left(\Sigma^T\Sigma\right)=\sum_{i=1}^{\min\{m,n\}}\sigma_i^2(A)\end{aligned}$$

where we use the property of unitary matrix and the cyclic property of trace.

6.6.7.1.2 Special case of SVD for symmetric matrices

The SVD for symmetric matrices is the unique case that interest us for practical purposes in this textbook (for the PCA: Principal Component Analysis). Therefore we will do a special focus on this latter case.

We will prove here in two steps that first, for a symmetric matrix, the eigenvectors are orthogonal and secondly that the Singular vectors and Singular values are respectively equal to the eigenvectors and eigenvalues for symmetric matrices.

Let us see the first step! In general, for any matrix, it's eigenvectors (when the exist) are NOT always orthogonal to each other. But for a special type of matrix, symmetric matrix, the eigenvalues are always real and the corresponding eigenvectors are always orthogonal!

Proof 6.45.2. Let us take a real symmetric matrix M and two distinct eigenvalues of M, λ_1 and λ_2, such that $M\vec{x}_1=\lambda_1\vec{x}_1$ and:

$$M\vec{x}_1=\lambda_1\vec{x}_1 \quad \text{and} \quad M\vec{x}_2=\lambda_2\vec{x}_2 \tag{6.6.467}$$

where $\vec{x}_1$ and $\vec{x}_2$ are obviously eigenvectors.

From $M\vec{x}_1=\lambda_1\vec{x}_1$, we get:

$$\vec{x}_2^TM\vec{x}_1=\lambda_1\vec{x}_2^T\vec{x}_1 \tag{6.6.468}$$

From $M\vec{x}_2=\lambda_2\vec{x}_2$, we similarly get:

$$\vec{x}_1^TM\vec{x}_2=\lambda_2\vec{x}_1^T\vec{x}_2 \tag{6.6.469}$$

But since M is symmetric:

$$\vec{x}_2^TM\vec{x}_1=\vec{x}_2^TM^T\vec{x}_1=\left(M\vec{x}_2\right)^T\vec{x}_1=\vec{x}_1^T\left(M\vec{x}_2\right)=\vec{x}_1^TM\vec{x}_2 \tag{6.6.470}$$

Also, clearly $\vec{x}_1^T\vec{x}_2=\vec{x}_2^T\vec{x}_1$. Thus:

$$\lambda_1\vec{x}_1^T\vec{x}_2=\lambda_2\vec{x}_1^T\vec{x}_2\,(\lambda_1-\lambda_2)\left(\vec{x}_1^T\vec{x}_2\right)=0 \tag{6.6.471}$$

But $\lambda_1-\lambda_2\neq 0$. Hence:

$$\vec{x}_1^T\vec{x}_2=\vec{x}_1^T\circ\vec{x}_2=0 \tag{6.6.472}$$

as required.

■ Q.E.D.

Now we treat the second step, for this let us consider A be a symmetric $n\times n$ matrix. Then the maximum value of $|A\vec{x}|$, where $\vec{x}$ ranges over unit vectors in $\mathbb{R}^n$, is the largest singular value σ_1, and this is achieved when $\vec{x}$ is an eigenvector of A^TA with eigenvalue σ_1^2.

Proof 6.45.3. Let $\vec{v}_1,\ldots,\vec{v}_n$ be an orthonormal basis for $\mathbb{R}^n$ consisting of eigenvectors of A^TA (indeed as A^TA is symmetric as $(AA^T)^T=(A^T)^TA^T=AA^T$ - this even if A is not symmetric itself - then according to the result just seen below, the eigenvectors are orthogonal) with eigenvalues σ_i^2. If $\vec{x}\in\mathbb{R}^n$, then we can expand $\vec{x}$ in this basis as:

$$\vec{x}=c_1\vec{v}_1+\ldots+c_n\vec{v}_n \tag{6.6.473}$$

for scalars $\{c_1,\ldots,c_n\}\in\mathbb{R}$ since $\vec{x}$ is a unit vector, $\|\vec{x}\|^2=1$, which (since the vectors $\vec{v}_1,\ldots,\vec{v}_n$ are orthonormal) means that:

$$c_1^2+\ldots+c_n^2=1 \tag{6.6.474}$$

On the other hand:

$$\|A\vec{x}\|^2=(A\vec{x})\circ(A\vec{x})=(A\vec{x})^T\circ(A\vec{x})=\vec{x}^T\circ A^TA\vec{x}=\vec{x}\circ\left(A^TA\vec{x}\right) \tag{6.6.475}$$

By:

$$\vec{x}=c_1\vec{v}_1+\ldots+c_n\vec{v}_n \tag{6.6.476}$$

since the $\vec{v}_i$ are eigenvectors of A^TA with eigenvalues σ_i^2, we have:

$$A^TA\vec{x}=c_1\sigma_1^2\vec{v}_1+\ldots+c_n\sigma_n^2\vec{v}_n \tag{6.6.477}$$

Taking the dot product with:

$$\vec{x}=c_1\vec{v}_1+\ldots+c_n\vec{v}_n \tag{6.6.478}$$

and using the fact that the vectors $\vec{v}_1,\ldots,\vec{v}_n$ are orthonormal, we get:

$$\vec{x}\circ\left(A^TA\vec{x}\right)=\|A\vec{x}\|^2=\sigma_1^2c_1^2+\ldots+\sigma_n^2c_n^2 \tag{6.6.479}$$

Since σ_1 is the largest singular value, we get:

$$\|A\vec{x}\|^2\leq\sigma_1^2\left(c_1^2+\ldots+c_n^2\right) \tag{6.6.480}$$

Equality holds when $c_1=1$ and $c_2=\ldots=c_n=0$. Thus the maximum value of $\|A\vec{x}\|^2$ for a unit vector $\vec{x}$ is the eigenvalue σ_1^2, which is achieved when $\vec{x}=\vec{v}_1$ (equality between the vector and one of the eigenvector of A^TA).

■ Q.E.D.

One can similarly show that σ_2 is the maximum of $\|A\vec{x}\|$ where $\vec{x}$ ranges over unit vectors that are orthogonal to $\vec{v}_1$. Likewise, σ_3 is the maximum of $\|A\vec{x}\|$ where $\vec{x}$ ranges over unit vectors that are orthogonal to $\vec{v}_1$ and $\vec{v}_2$; and so forth.

So that's why in the case of symmetric (obviously square) matrices, the SVD traditionally denoted:

$$A = U\Sigma V^T \tag{6.6.481}$$

is then denoted (remember that Λ is the upper case letter of λ, that latter being the traditional notation of eigenvalues):

$$\boxed{A = U\Lambda V^T} \tag{6.6.482}$$

A common question that we can find on Internet forums is: *Why are singular values always non-negative?*

To answer let us take some, non zero singular value σ_i. We can reverse the sign if it is positive. That is, $-\sigma_i = -\sqrt{\lambda_i^2} = -\lambda_i$ where λ_i is an eigenvalue of A^TA corresponding to an eigenvector v_i. That is $A^TAv_i = \lambda_i^2 v_i$.

Who can stop us to write instead $A^TA(-v_i) = \lambda_i^2(-v_i)$? What this means is that we can reverse the sign of a singular value, but then we need to go to the matrix V and reverse the sign of its corresponding eigenvector column.

Hence, there is not a unique way to write $A = UDV^T$. But if we decide that all σ_i are non-negative, then "yes" there is a unique way to write $A = UDV^T$. Of course all σ_i are sorted from largest to smallest (otherwise there would be a bunch of possibilities by permuting any two columns of U and V and their corresponding eigenvalues).

6.6.7.1.3 Orthogonal decomposition (eigenvalue spectral decomposition)

Let us come back to:

$$M = UDV^T \tag{6.6.483}$$

If M is symmetric, than it is a square matrix. Then obviously U and V are also square matrices have the same dimensions as those of M.

If M symmetric, then it is also obviously equal to it's transpose M^T, so if we do the SVD of the transpose we should get the same decomposition as M^T such that:

$$M = UDV^T = M^T = (UDV^T)^T \tag{6.6.484}$$

But as we have proved it during our study of matrix transposition (see page 1951), we have:

$$(UDV^T)^T = (V^T)^T D^T U^T \tag{6.6.485}$$

But we should have the equality:

$$(V^T)^T D^T U^T = UDV^T \tag{6.6.486}$$

Therefore:

$$U = V \tag{6.6.487}$$

So that for symmetric matrices M we have:

$$\boxed{M=UDV^T=UDU^T=VDV^T} \tag{6.6.488}$$

As before V (so was U) is orthogonal but now it is also a square matrix. In this case, as a reminder by definition (the inverse of an orthogonal matrix is by definition equal to its transpose):

$$U^{-1}=U^T \tag{6.6.489}$$

So that finally for symmetric matrices M, we get the special case of SVD, named the "orthogonal decomposition" or "eigenvalue spectral decomposition":

$$\boxed{M=UDV^T=UDU^T=UDU^{-1}} \tag{6.6.490}$$

Also often denoted for the obvious reason already mentioned above:

$$M=U\Lambda V^T=U\Lambda U^T=U\Lambda U^{-1} \tag{6.6.491}$$

Be careful to not make a confusion between Spectral Value Decomposition (SVD), also named Singular Value Decomposition, and Eigenvalue Spectral Decomposition (EVD) that is the special case of SVD but for square symmetric matrices! So that means in order for the SVD of a matrix M to be equal to its eigendecomposition we need M to:

- Have orthonormal eigenvectors (hence be a symmetric real matrix)
- Have positive eigenvalues (colloquially, it must be a real matrix and not "flip" anything)

Notice that also the square root of M (written here as $M^{1/2}$) - such that $M^{1/2}M^{1/2}=M$ - can be easily found to be:

$$M^{1/2}=U\Lambda^{1/2}U^T \tag{6.6.492}$$

Indeed, we can easily check that this equality is correct:

$$M^{1/2}M^{1/2}=U\Lambda^{1/2}U^TU\Lambda^{1/2}U^T=U\Lambda^{1/2}\mathbb{1}\Lambda^{1/2}U^T=U\Lambda U^T=M \tag{6.6.493}$$

Another useful result for later (study of the statistical distribution of the Mahalanobis distance) is the eigenvalue decomposition of the inverse of a matrix M using the relation about invertible matrices proved at page 1951 and the associative property of the matrix product:

$$M^{-1}=\left(U\Lambda U^{-1}\right)^{-1}=\left(U^{-1}\right)^{-1}\Lambda^{-1}U^{-1}=U\Lambda^{-1}U^{-1}=U\Lambda^{-1}U^T=\sum_{k=1}^{n}\lambda^{-1}\vec{u}_i\vec{u}_i^T \tag{6.6.494}$$

6.6.7.2 LU Decomposition

As an alternative to Gaussian elimination, a non-singular matrix A may be written in the form $A=LU$ where L is a lower triangular matrix (all entries above the main diagonal are zero) and all the entries on the main diagonal are unity:

$$\boxed{A=\begin{bmatrix}a_{11}&a_{12}&\cdots&a_{1n}\\a_{21}&a_{22}&\cdots&a_{2n}\\\vdots&\vdots&\ddots&\vdots\\a_{m1}&a_{m2}&\cdots&a_{mn}\end{bmatrix}=LU=\begin{bmatrix}1&0&\cdots&0\\l_{21}&1&\cdots&0\\\vdots&\vdots&1&\vdots\\l_{m1}&l_{m2}&\cdots&1\end{bmatrix}\begin{bmatrix}u_{11}&u_{12}&\cdots&u_{1n}\\0&u_{22}&\cdots&u_{2n}\\\vdots&\vdots&\ddots&\vdots\\0&0&\cdots&u_{mn}\end{bmatrix}}\qquad(6.6.495)$$

This is known as the "LU decomposition" or "LU factorization" or "triangular triangularization".

Remark

LU decomposition is not unique: if $A=LU$, then $A=LDD^{-1}U=(LD)(D^{-1}U)=L'U'$ is again an LU decomposition, if D is a diagonal matrix. An additional assumption $l_{ii}=1$, $\forall i=1,\ldots,n$, (impose that L is a lower triangular unit matrix) guarantees the uniqueness.

For example (three by three case):

$$L=\begin{bmatrix}1&0&0\\l_{21}&1&0\\l_{31}&l_{32}&1\end{bmatrix}\qquad(6.6.496)$$

U is an upper triangular matrix (all entries below the main diagonal are zero). For example (three by three case):

$$U=\begin{bmatrix}u_{11}&u_{12}&u_{13}\\0&u_{22}&u_{23}\\0&0&u_{33}\end{bmatrix}\qquad(6.6.497)$$

The method of LU decomposition involves writing the system $A\vec{x}=\vec{b}$ as $LU\vec{x}=\vec{b}$. If $U\vec{x}$ is written as $\vec{y}$, the system becomes $L\vec{y}=\vec{b}$. Due to the form of L (triangular matrices make the solution straightforward), $\vec{y}$ may be found quickly. Once this is done, the equation $U\vec{x}=\vec{y}$ may be solved for $\vec{x}$.

The tricky bit is probably finding L and U. For a 3×3 matrix A.

Let:

$$\begin{aligned}A=\begin{bmatrix}a_{11}&a_{12}&a_{13}\\a_{21}&a_{22}&a_{23}\\a_{31}&a_{32}&a_{33}\end{bmatrix}&=\begin{bmatrix}1&0&0\\l_{21}&1&0\\l_{31}&l_{32}&1\end{bmatrix}\begin{bmatrix}u_{11}&u_{12}&u_{13}\\0&u_{22}&u_{23}\\0&0&u_{33}\end{bmatrix}\\&=\begin{bmatrix}u_{11}&u_{12}&u_{13}\\u_{11}l_{21}&u_{12}l_{21}+u_{22}&u_{13}l_{21}+u_{23}\\u_{11}l_{31}&u_{12}l_{31}+u_{22}l_{32}&u_{13}l_{31}+u_{23}l_{32}+u_{33}\end{bmatrix}\end{aligned}\qquad(6.6.498)$$

Equating coefficients:

$$\begin{array}{rlrlrl} a_{11}=u_{11} & [1] & a_{12}=u_{12} & [4] & a_{13}=u_{13} & [7] \\ a_{21}=l_{21}u_{11} & [2] & a_{22}=l_{21}u_{12}+u_{22} & [5] & a_{23}=l_{21}u_{13}+u_{23} & [8] \\ a_{31}=l_{31}u_{11} & [3] & a_{32}=l_{31}u_{12}+l_{32}u_{22} & [6] & a_{33}=l_{31}u_{13}+l_{32}u_{23}+u_{33} & [9] \end{array} \tag{6.6.499}$$

These equations may be solved as follows:

- Solve [1] for u_{11}
- Solve [2] for l_{21}
- Solve [3] for l_{31}
- Solve [4] for u_{12}
- Solve [7] for u_{13}
- Solve [5] for u_{22}
- Solve [6] for l_{32}
- Solve [8] for u_{23}
- Solve [9] for u_{33}

This procedure seems to be named the "Crout's algorithm".

As companion example let's solve:

$$\underbrace{\begin{bmatrix} -1 & 1 & -1 \\ -2 & 4 & -2 \\ 1 & 1 & 4 \end{bmatrix}}_{A} \underbrace{\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}}_{\vec{x}} = \underbrace{\begin{bmatrix} -2 \\ -6 \\ 9 \end{bmatrix}}_{\vec{b}} \tag{6.6.500}$$

Let:

$$A = \begin{bmatrix} -1 & 1 & -1 \\ -2 & 4 & -2 \\ 1 & 1 & 4 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ l_{21} & 1 & 0 \\ l_{31} & l_{32} & 1 \end{bmatrix} \begin{bmatrix} u_{11} & u_{12} & u_{13} \\ 0 & u_{22} & u_{23} \\ 0 & 0 & u_{33} \end{bmatrix} \tag{6.6.501}$$

i.e.:

$$\begin{bmatrix} -1 & 1 & -1 \\ -2 & 4 & -2 \\ 1 & 1 & 4 \end{bmatrix} = \begin{bmatrix} u_{11} & u_{12} & u_{13} \\ l_{21}u_{11} & l_{21}u_{12}+u_{22} & l_{21}u_{13}+u_{23} \\ l_{31}u_{11} & l_{31}u_{12}+l_{32}u_{22} & l_{31}u_{13}+l_{32}u_{23}+u_{33} \end{bmatrix} \tag{6.6.502}$$

so, comparing coefficients:

$$\begin{array}{lll} u_{11}=-1 & u_{12}=1 & u_{13}=-1 \\ l_{21}=\frac{-2}{-1}=2 & u_{22}=4-2\cdot 1=2 & u_{23}=-2-2\cdot(-1)=0 \\ l_{31}=\frac{1}{-1}=-1 & l_{32}=\frac{1-(-1)\cdot 1}{2}=1 & u_{33}=4-(-1)\cdot(-1)-1\cdot 0=3 \end{array} \tag{6.6.503}$$

Or written in a more general way for U:

$$\begin{aligned} u_{11} &= a_{11} \\ u_{12} &= a_{12} \\ u_{13} &= a_{13} \\ u_{22} &= a_{22} - u_{12}l_{21} \\ u_{23} &= a_{23} - u_{13}l_{21} \\ u_{33} &= a_{33} - (u_{13}l_{31} + u_{23}l_{32}) \end{aligned} \tag{6.6.504}$$

and for L:

$$\begin{aligned} l_{21} &= \frac{1}{u_{11}}a_{21} \\ l_{31} &= \frac{1}{u_{11}}a_{31} \\ l_{32} &= \frac{1}{u_{22}}(a_{32} - u_{12}l_{31}) \end{aligned} \tag{6.6.505}$$

We see that there is a calculation pattern, which can be expressed as the following relations:

$$\boxed{u_{ij} = a_{ij} - \sum_{k=1}^{i-1} u_{kj}l_{ik} \qquad l_{ij} = \frac{1}{u_{jj}}(a_{ij} - \sum_{k=1}^{j-1} u_{kj}l_{ik})} \tag{6.6.506}$$

Remark

We notice in the second relation that to get the l_{ij} below the diagonal, we have to divide by the diagonal element (pivot) u_{jj} , so we get problems when u_{jj} is either 0 or very small, which leads to numerical instability.

Therefore:

$$A = LU = \begin{bmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ -1 & 1 & 1 \end{bmatrix} \begin{bmatrix} -1 & 1 & -1 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix} \tag{6.6.507}$$

The equation $LU\vec{x} = \vec{b}$ becomes $L\vec{y} = \vec{b}$ i.e.:

$$\begin{bmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ -1 & 1 & 1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} -2 \\ -6 \\ 9 \end{bmatrix} \tag{6.6.508}$$

So (this procedure is named "forward substitution"):

$$\begin{array}{ccccccc} y_1 & & & & & = & -2 \\ 2y_1 & + & y_2 & & & = & -6 \\ -y_1 & + & y_2 & + & y_3 & = & 9 \end{array} \qquad \begin{aligned} y_1 &= -2 \\ y_2 &= -2 \\ y_3 &= 9 \end{aligned} \tag{6.6.509}$$

Where in general we can see that the pattern is:

$$\begin{aligned} y_1 &= \frac{b_1}{l_{11}} \\ y_i &= \frac{1}{l_{ii}}\left(b_i - \sum_{j=1}^{i-1} l_{ij}y_i\right) \qquad i = 2, 3, \ldots, n \end{aligned} \tag{6.6.510}$$

The equation $U\vec{x}=\vec{y}$ becomes:

$$\begin{bmatrix} -1 & 1 & -1 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}=\begin{bmatrix} -2 \\ -2 \\ 9 \end{bmatrix} \tag{6.6.511}$$

So (this procedure is named "backward substitution"):

$$\begin{array}{rcrcrcr} -x_1 & + & x_2 & - & x_3 & = & -2 \\ & & 2x_2 & & & = & -2 \\ & & & & x_3 & = & 9 \end{array} \qquad \begin{array}{l} x_1=-2 \\ x_2=-1 \\ x_3=3 \end{array} \tag{6.6.512}$$

Where in general we can see that the pattern is:

$$\begin{aligned} x_n &= \frac{y_n}{u_{nn}} \\ x_i &= \frac{1}{u_{ii}}\left(y_i-\sum_{j=i+1}^{n} u_{ij}x_j\right) \qquad i=n-1,n-2,\ldots,1 \end{aligned} \tag{6.6.513}$$

For large matrices, this procedure involves fewer operations than Gaussian elimination. However, Gaussian Elimination is probably easier to program.

The matrix U is identical to the triangular matrix found in Gaussian Elimination; $\vec{y}$ is identical to the right hand side immediately before the back-substitution.

LU decomposition can be viewed as the matrix form of Gaussian elimination. Computers usually solve square systems of linear equations using LU decomposition, and it is also a key step when inverting a matrix or computing the determinant of a matrix. LU decomposition was introduced by mathematician Tadeusz Banachiewicz in 11938 (holocene calendar).

6.6.7.3 Cholesky's Decomposition

The Cholesky decomposition is another way of solving systems of linear equations. It can be significantly faster and uses less memory than the LU decomposition by exploiting the property of symmetric matrices. However, it is required that the matrix being decomposed be Hermitian (or real-valued symmetric and thus square) and positive definite.

For many symmetric matrices (strictly speaking for positive definite matrices[30] $\vec{x}^T A\vec{x}>0$ for all $\vec{x}\neq 0$ as detailed at page 1957), LU decomposition can be carried out using $U=L^T$. Therefore:

$$\boxed{A=\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix}=LU=L(L^T)=LL^T=\begin{bmatrix} l_{11} & 0 & \cdots & 0 \\ l_{21} & l_{22} & \cdots & 0 \\ \vdots & \vdots & l_{33} & \vdots \\ l_{m1} & l_{m2} & \cdots & l_{mn} \end{bmatrix}\begin{bmatrix} l_{11} & l_{12} & \cdots & l_{1n} \\ 0 & l_{22} & \cdots & l_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & l_{mn} \end{bmatrix}} \tag{6.6.514}$$

This is known as the "Cholesky's decomposition". While the Cholesky decomposition only works for symmetric, positive definite matrices, the more general LU decomposition works for any square matrix!

---

[30] Don't forget that the variance-covariance matrix is a positive definite matrix!

As companion example, let us use Cholesky's method to solve:

$$\underbrace{\begin{bmatrix} 4 & -2 & 2 \\ -2 & 17 & -1 \\ 2 & -1 & 10 \end{bmatrix}}_{A} \underbrace{\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}}_{\vec{x}} = \underbrace{\begin{bmatrix} 14 \\ -55 \\ 7 \end{bmatrix}}_{\vec{b}} \tag{6.6.515}$$

Let:

$$A = \begin{bmatrix} 4 & -2 & 2 \\ -2 & 17 & -1 \\ 2 & -1 & 10 \end{bmatrix} = \begin{bmatrix} l_{11} & 0 & 0 \\ l_{21} & l_{22} & 0 \\ l_{31} & l_{32} & l_{33} \end{bmatrix} \begin{bmatrix} l_{11} & l_{21} & l_{31} \\ 0 & l_{22} & l_{32} \\ 0 & 0 & l_{33} \end{bmatrix} \tag{6.6.516}$$

i.e.:

$$\begin{bmatrix} 4 & -2 & 2 \\ -2 & 17 & -1 \\ 2 & -1 & 10 \end{bmatrix} = \begin{bmatrix} l_{11}^2 & l_{11}l_{21} & l_{11}l_{31} \\ l_{11}l_{21} & l_{21}^2 + l_{22}^2 & l_{21}l_{31} + l_{22}l_{32} \\ l_{11}l_{31} & l_{21}l_{31} + l_{22}l_{32} & l_{31}^2 + l_{32}^2 + l_{33}^2 \end{bmatrix} \tag{6.6.517}$$

So:

$$\begin{aligned} l_{11}^2 &= 4 & [1] \\ l_{11}l_{21} &= -2 & [2] \\ l_{11}l_{31} &= 2 & [3] \\ l_{21}^2 + l_{22}^2 &= 17 & [4] \\ l_{21}l_{31} + l_{22}l_{32} &= -1 & [5] \\ l_{31}^2 + l_{32}^2 + l_{33}^2 &= 10 & [6] \end{aligned} \tag{6.6.518}$$

Plus duplicates of [2], [3] and [5]:

- From [1], $l_{11} = 2$,
- From [2], $l_{21} = -1$,
- From [3], $l_{31} = 1$,
- From [4], $l_{22} = 4$,
- From [5], $l_{32} = 0$,
- From [6], $l_{33} = 3$

So:

$$L = \begin{bmatrix} 2 & 0 & 0 \\ -1 & 4 & 0 \\ 1 & 0 & 3 \end{bmatrix} \tag{6.6.519}$$

The system becomes:

$$\begin{bmatrix} 2 & 0 & 0 \\ -1 & 4 & 0 \\ 1 & 0 & 3 \end{bmatrix} \begin{bmatrix} 2 & -1 & 1 \\ 0 & 4 & 0 \\ 0 & 0 & 3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 14 \\ -55 \\ 7 \end{bmatrix} \tag{6.6.520}$$

i.e:

$$\begin{bmatrix} 2 & 0 & 0 \\ -1 & 4 & 0 \\ 1 & 0 & 3 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} 14 \\ -55 \\ 7 \end{bmatrix} \tag{6.6.521}$$

so:

$$\begin{array}{ccccccccc} 2y_1 & & & & & = & 14 & \qquad & y_1=7 \\ -y_1 & + & 4y_2 & & & = & -55 & & y_2=-12 \\ y_1 & & & + & 3y_3 & = & 7 & & y_3=0 \end{array} \tag{6.6.522}$$

$\vec{x}$ satisfies i.e.:

$$\begin{bmatrix} 2 & -1 & 1 \\ 0 & 4 & 0 \\ 0 & 0 & 3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 7 \\ -12 \\ 0 \end{bmatrix} \tag{6.6.523}$$

$$\begin{array}{ccccccccc} 2x_1 & - & x_2 & + & x_3 & = & 7 & \qquad & x_1=2 \\ & & 4x_2 & & & = & -12 & & x_2=-3 \\ & & & & 3x_3 & = & 0 & & x_3=2 \end{array} \tag{6.6.524}$$

We can see that from the above example that the diagonal elements l_{kk} of L have a calculation pattern:

$$l_{11}=\sqrt{a_{11}}\quad l_{22}=\sqrt{a_{22}-l_{21}^2}\quad l_{33}=\sqrt{a_{33}-(l_{31}^2+l_{32}^2)} \tag{6.6.525}$$

For the elements below the diagonal (l_{ik} , where $i>k$) there is also a calculation pattern:

$$l_{21}=\frac{1}{l_{11}}a_{21}\quad l_{31}=\frac{1}{l_{11}}a_{31}\quad l_{32}=\frac{1}{l_{22}}(a_{32}-l_{31}l_{21}) \tag{6.6.526}$$

We see that the both cases have a pattern that can be written respectively:

$$\boxed{l_{kk}=\sqrt{a_{kk}-\sum_{j=1}^{k-1}l_{kj}^2}\qquad l_{ik}=\frac{1}{l_{kk}}\left(a_{ik}-\sum_{j=1}^{k-1}l_{ij}l_{kj}\right)} \tag{6.6.527}$$

We can now understand for what the positive definiteness was necessary! Indeed, the positive definiteness of A guarantees that all square roots are real. We can also notice from the above developments that L needs to have positive diagonal entries[31]!

Suppose now a matrix A factors as $A=L^TL$. Then:

$$\begin{aligned} \vec{x}^TA\vec{x} &= \vec{x}^TL^TL\vec{x} \\ &= (L\vec{x})^T(L\vec{x}) \\ &= \|L\vec{x}\|^2 \\ &\geq 0 \end{aligned} \tag{6.6.528}$$

---

[31] The reader should however not forget that from what we have seen during our study of positive definite matrices, the fact that all entries are positive and that the matrix is symmetric is not enough to make it positive definite

This shows that A is positive semidefinite.

If we further assume that L is square and triangular with positive real diagonal entries, then L is invertible, so $L\vec{x}=\vec{0}\Leftrightarrow\vec{x}=\vec{0}$. In this case, we see that A is positive definite.

Some textbooks use Cholesky decomposition to define what makes a matrix positive definite. Indeed, such textbooks only say that any matrix A that can uniquely be written under a Cholesky decomposition $A=L^TL$ are positive definite matrices.

> **Remark**
>
> The above algorithms show that every positive definite matrix A has a Cholesky decomposition. This result can be extended to the positive semi-definite matrix! However for positive semi-definite, it is possible but not for sure the Cholesky decomposition is not unique.

6.6.7.4 QR Decomposition

A "QR decomposition", also named a "QR factorization", of a matrix is a decomposition of any real matrix A into a product $A=QR$ of an orthogonal matrix Q and an upper triangular matrix R:

$$\boxed{\begin{aligned}A=\begin{bmatrix}a_{11}&a_{12}&\cdots&a_{1n}\\a_{21}&a_{22}&\cdots&a_{2n}\\\vdots&\vdots&\ddots&\vdots\\a_{m1}&a_{m2}&\cdots&a_{mn}\end{bmatrix}=QR=\begin{bmatrix}q_{11}&q_{12}&\cdots&q_{1n}\\q_{21}&q_{22}&\cdots&q_{2n}\\\vdots&\vdots&\ddots&\vdots\\q_{m1}&q_{m2}&\cdots&q_{mn}\end{bmatrix}\begin{bmatrix}r_{11}&r_{12}&\cdots&r_{1n}\\0&r_{22}&\cdots&l_{2n}\\\vdots&\vdots&\ddots&\vdots\\0&0&\cdots&r_{mn}\end{bmatrix}\\=[\text{col}_1(Q)|\text{col}_2(Q)|\ldots|\text{col}_n(Q)][\text{col}_1(R)|\text{col}_2(R)|\ldots|\text{col}_n(R)]\end{aligned}} \tag{6.6.529}$$

with $\text{col}_i(Q)\circ\text{col}_j(Q)=0,\forall i\neq j$ and (we will show if further below) $r_{ij}=\text{col}_i(Q)\circ\text{col}_j(A),\forall 1\leq 1\leq i\leq n$.

There are actually several methods to compute the QR decomposition, but we will focus here on the Gram–Schmidt process whose idea is described in details at page 2062.

So let us consider the Gram–Schmidt process applied to the columns of the matrix A and let us recall the result that we have derived during our study of the Gram–Schmidt process:

$$\begin{aligned}\vec{e}_1&=\vec{x}_1\\\vec{e}_2&=\vec{x}_2-\frac{\vec{e}_1\circ\vec{x}_2}{\|\vec{e}_1\|^2}\vec{e}_1=\vec{x}_2-\text{proj}_{e_1}\vec{x}_2\\\vec{e}_3&=-\frac{\vec{e}_1\circ\vec{x}_3}{\|\vec{e}_1\|^2}\vec{e}_1-\frac{\vec{e}_2\circ\vec{x}_3}{\|\vec{e}_2\|^2}\vec{e}_2+\vec{x}_3=-\text{proj}_{e_1}\vec{x}_3-\text{proj}_{e_2}\vec{x}_2+\vec{x}_3\end{aligned} \tag{6.6.530}$$

That we will rewrite in our case:

$$\begin{aligned}
&\vec{u}_1=\text{col}_1(A)\\
&\vec{u}_2=\text{col}_2(A)-\frac{\vec{u}_1\circ\text{col}_2(A)}{\|\vec{u}_1\|^2}\vec{u}_1=\text{col}_2(A)-\text{proj}_{u_1}\text{col}_2(A)\\
&\vec{u}_3=-\frac{\vec{u}_1\circ\text{col}_3(A)}{\|\vec{u}_1\|^2}\vec{e}_1-\frac{\vec{u}_2\circ\text{col}_3(A)}{\|\vec{u}_2\|^2}\vec{u}_2+\text{col}_3(A)=-\text{proj}_{u_1}\text{col}_3(A)-\text{proj}_{u_2}\text{col}_2(A)+\text{col}_3(A)\\
&\quad\vdots\\
&\vec{u}_k=\text{col}_k(A)-\sum_{j=1}^{k-1}\text{proj}_{u_j}\text{col}_k(A)
\end{aligned}\tag{6.6.531}$$

And in the QR decomposition it is traditional to take:

$$\text{col}_i(Q)=\vec{e}_i=\frac{\vec{u}_i}{\|\vec{u}_i\|}\tag{6.6.532}$$

Therefore with this tradition we have (Q is then not only orthogonal but orthonormal!):

$$Q=[\vec{e}_1|\vec{e}_2|\ldots|\vec{e}_n]\tag{6.6.533}$$

Before we continue, let us show a companion example. Let us consider the matrix:

$$A=\begin{bmatrix}-1&3\\1&5\end{bmatrix}\tag{6.6.534}$$

Let us carry out the Gram-Schmidt process with the columns $\text{col}_1(A)$ and $\text{col}_2(A)$:

$$\begin{aligned}
&\vec{u}_1=\text{col}_1(A)=\begin{bmatrix}-1\\1\end{bmatrix}\\
&\vec{e}_1=\frac{\vec{u}_1}{\|\vec{u}_1\|}=\frac{1}{\sqrt{2}}\begin{bmatrix}-1\\1\end{bmatrix}\\
&\vec{u}_2=\text{col}_2(A)-\text{proj}_{u_1}=\text{col}_2(A)-\frac{\vec{u}_1\circ\text{col}_2(A)}{\|\vec{u}_1\|^2}\vec{u}_1=\text{col}_2(A)-(\vec{e}_1\circ\text{col}_2(A))\vec{e}_1\\
&\quad=\begin{bmatrix}3\\5\end{bmatrix}-\frac{(-3+5)}{\sqrt{2}}\frac{1}{\sqrt{2}}\begin{bmatrix}-1\\1\end{bmatrix}=\begin{bmatrix}3\\5\end{bmatrix}-\sqrt{2}\frac{1}{\sqrt{2}}\begin{bmatrix}-1\\1\end{bmatrix}=\begin{bmatrix}3\\5\end{bmatrix}-\begin{bmatrix}-1\\1\end{bmatrix}=\begin{bmatrix}4\\4\end{bmatrix}\\
&\vec{e}_2=\frac{\vec{u}_2}{\|\vec{u}_2\|}=\frac{1}{4\sqrt{2}}\begin{bmatrix}4\\4\end{bmatrix}=\frac{1}{\sqrt{2}}\begin{bmatrix}1\\1\end{bmatrix}
\end{aligned}\tag{6.6.535}$$

That is how the Gram-Schmidt process produces the matrix Q. Here are one of the methods to find R.

For this the reader must understand (and see!) that at each step of Gram-Schmidt procedure, the operations on the vectors correspond to column operations A, which correspond to multiplying by elementary matrices on the right. Let us write all those matrices:

$$\begin{aligned}
A &= \begin{bmatrix} -1 & 3 \\ 1 & 5 \end{bmatrix} \\
A \begin{bmatrix} \frac{1}{\sqrt{2}} & 0 \\ 0 & 1 \end{bmatrix} &= \begin{bmatrix} -\frac{1}{\sqrt{2}} & 3 \\ \frac{1}{\sqrt{2}} & 5 \end{bmatrix} \\
A \begin{bmatrix} \frac{1}{\sqrt{2}} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -\sqrt{2} \\ 0 & 1 \end{bmatrix} &= \begin{bmatrix} -\frac{1}{\sqrt{2}} & 4 \\ \frac{1}{\sqrt{2}} & 4 \end{bmatrix} \\
A \begin{bmatrix} \frac{1}{\sqrt{2}} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -\sqrt{2} \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & \frac{1}{4\sqrt{2}} \end{bmatrix} &= \begin{bmatrix} -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix} = Q
\end{aligned} \tag{6.6.536}$$

From this we get (using the properties on the inverse matrices):

$$\begin{aligned}
A &= Q \left(\begin{bmatrix} \frac{1}{\sqrt{2}} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -\sqrt{2} \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & \frac{1}{4\sqrt{2}} \end{bmatrix} \right)^{-1} \\
&= Q \begin{bmatrix} 1 & 0 \\ 0 & \frac{1}{4\sqrt{2}} \end{bmatrix}^{-1} \begin{bmatrix} 1 & -\sqrt{2} \\ 0 & 1 \end{bmatrix}^{-1} \begin{bmatrix} \frac{1}{\sqrt{2}} & 0 \\ 0 & 1 \end{bmatrix}^{-1} \\
&= Q \begin{bmatrix} 1 & 0 \\ 0 & 4\sqrt{2} \end{bmatrix} \begin{bmatrix} 1 & \sqrt{2} \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \sqrt{2} & 0 \\ 0 & 1 \end{bmatrix} \\
&= Q \begin{bmatrix} \sqrt{2} & \sqrt{2} \\ 0 & 4\sqrt{2} \end{bmatrix} = QR
\end{aligned} \tag{6.6.537}$$

We have found:

$$R = \begin{bmatrix} \sqrt{2} & \sqrt{2} \\ 0 & 4\sqrt{2} \end{bmatrix} = \sqrt{2} \begin{bmatrix} 1 & 1 \\ 0 & 4 \end{bmatrix} \tag{6.6.538}$$

Let us check the factorization:

$$QR = \frac{1}{\sqrt{2}} \begin{bmatrix} -1 & 1 \\ 1 & 1 \end{bmatrix} \sqrt{2} \begin{bmatrix} 1 & 1 \\ 0 & 4 \end{bmatrix} = \begin{bmatrix} -1 & 3 \\ 1 & 5 \end{bmatrix} = A \tag{6.6.539}$$

Let us rewrite the equalities using symbols, in order to get the general relation:

$$\begin{aligned}
A &= [\text{col}_1(A), \text{col}_2(A)] = [\vec{u}_1, \text{col}_2(A)] \\
A \begin{bmatrix} \frac{1}{\|\vec{u}_1\|} & 0 \\ 0 & 1 \end{bmatrix} &= \begin{bmatrix} \frac{\vec{u}_1}{\|\vec{u}_1\|} & \text{col}_2(A) \end{bmatrix} = [\vec{e}_1, \text{col}_2(A)] \\
A \begin{bmatrix} \frac{1}{\|\vec{u}_1\|} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -(\vec{e}_1 \circ \text{col}_2(A)) \\ 0 & 1 \end{bmatrix} &= [\vec{e}_1, \text{col}_2(A) - (\vec{e}_1 \circ \text{col}_2(A))\vec{e}_1] = [\vec{e}_1, \vec{u}_1] \\
A \begin{bmatrix} \frac{1}{\|\vec{u}_1\|} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -(\vec{e}_1 \circ \text{col}_2(A)) \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & \frac{1}{\|\vec{u}_2\|} \end{bmatrix} &= \begin{bmatrix} \vec{e}_1, \frac{\vec{u}_2}{\|\vec{u}_2\|} \end{bmatrix} = [\vec{e}_1, \vec{e}_2] = Q
\end{aligned} \tag{6.6.540}$$

From this we get:

$$\begin{aligned}A&=Q\left(\begin{bmatrix}\dfrac{1}{\|\vec{u}_1\|} & 0\\ 0 & 1\end{bmatrix}\begin{bmatrix}1 & -(\vec{e}_1\circ\text{col}_2(A))\\ 0 & 1\end{bmatrix}\begin{bmatrix}1 & 0\\ 0 & \dfrac{1}{\|\vec{u}_2\|}\end{bmatrix}\right)^{-1}\\&=Q\begin{bmatrix}1 & 0\\ 0 & \dfrac{1}{\|\vec{u}_2\|}\end{bmatrix}^{-1}\begin{bmatrix}1 & -(\vec{e}_1\circ\text{col}_2(A))\\ 0 & 1\end{bmatrix}^{-1}\begin{bmatrix}\dfrac{1}{\|\vec{u}_1\|} & 0\\ 0 & 1\end{bmatrix}^{-1}\\&=Q\begin{bmatrix}1 & 0\\ 0 & \|\vec{u}_2\|\end{bmatrix}\begin{bmatrix}1 & \vec{e}_1\circ\text{col}_2(A)\\ 0 & 1\end{bmatrix}\begin{bmatrix}\|\vec{u}_1\| & 0\\ 0 & 1\end{bmatrix}\\&=Q\begin{bmatrix}\|\vec{u}_1\| & \vec{e}_1\circ\text{col}_2(A)\\ 0 & \|\vec{u}_2\|\end{bmatrix}=QR\end{aligned}\qquad(6.6.541)$$

This relation for R generalizes to any value of n. For example, if n were 3, R would be given by:

$$R=\begin{bmatrix}\|\vec{u}_1\| & \vec{e}_1\circ\text{col}_2(A) & \vec{e}_1\circ\text{col}_3(A)\\ 0 & \|\vec{u}_2\| & \vec{e}_2\circ\text{col}_2(A)\\ 0 & 0 & \|\vec{u}_3\|\end{bmatrix}\qquad(6.6.542)$$

Knowing this, there is no need to rewrite the whole computation every time. We can just build the matrix R as we go along the Gram-Schmidt process. So more generally:

$$R=\begin{bmatrix}\|\vec{u}_{11}\| & \vec{e}_1\circ\text{col}_2(A) & \cdots & \vec{e}_1\circ\text{col}_n(A)\\ 0 & \|\vec{u}_{22}\| & \cdots & \vec{e}_2\circ\text{col}_n(A)\\ \vdots & \vdots & \ddots & \vdots\\ 0 & 0 & \cdots & \|\vec{u}_{mn}\|\end{bmatrix}\qquad(6.6.543)$$

There is also another way to get R. Indeed, the fact that Q has orthonormal columns can be restated as we know as $Q^TQ=\mathbb{1}$. In particular, Q has a left inverse, namely Q^T. From this find R:

$$A=QR\Rightarrow Q^TA=Q^TQR=R\qquad(6.6.544)$$

In other words, the relation:

$$R=Q^TA\qquad(6.6.545)$$

holds, no matter what the dimensions of the matrix.

If we take back our example, let us recall that we had:

$$A=\begin{bmatrix}-1 & 3\\ 1 & 5\end{bmatrix}\qquad Q=\frac{1}{\sqrt{2}}\begin{bmatrix}-1 & 1\\ 1 & 1\end{bmatrix}\qquad(6.6.546)$$

Then:

$$R=Q^TA=\frac{1}{\sqrt{2}}\begin{bmatrix}-1 & 1\\ 1 & 1\end{bmatrix}\begin{bmatrix}-1 & 3\\ 1 & 5\end{bmatrix}=\frac{1}{\sqrt{2}}\begin{bmatrix}2 & 2\\ 0 & 8\end{bmatrix}=\sqrt{2}\begin{bmatrix}1 & 1\\ 0 & 4\end{bmatrix}\qquad(6.6.547)$$

So to summarize:

Factorization	Restrictions	Properties of Factors
SVD $A_{nm} = U_{nn} D_{nm} V^T_{mm}$	none	U orthogonal V orthogonal D non-negative
	variations: for symmetric A, $A = VCV^T$	
LU $A_{nn} = L_{nn} U_{nn}$	A square, (others)	L full-rank lower triangular U upper triangular
variations:	with partial pivoting, $A = LP$ with full pivoting, $P_1 A P_2 = LU$ $A = LDU$, with D diagonal and $U_{ii} = 1$	
QR $A_{nm} = Q_{nn} R_{nm}$	none	Q orthogonal R upper triangular
	variations: skinny QR for $n > m$, $A = Q_1 R_1$	
Cholesky $A_{nn} = L_{nn} U_{nn}$	A non-negative definite	L full-rank lower triangular U upper triangular
Diagonal (i.e. orthogonal) $A_{nn} = V_{nn} C_{nn} V^T_{nn}$	A symmetric	V orthogonal C diagonal
Square root $A_{nn} = (A^{1/2}_{nn})^2$	A non-negative definite	$A^{1/2}_{nn}$ non-negative definite

Table 6.20: **Matrix Factorizations**

6.6.8 Woodbury Matrix identity and Sherman-Morrison relation

The "Woodbury matrix identity" gives the inverse of an $n \times n$ square matrix A modified by a perturbation term UBV^T:

$$(A+UBV^T)^{-1}=A^{-1}-A^{-1}U(B^{-1}+V^TA^{-1}U)^{-1}V^TA^{-1} \tag{6.6.548}$$

It is a very useful result for our study on the inverse and determinant of a partitioned symmetric matrix (itself useful for the Factor Analysis statistical tool). It has also other practical application like for PPCA (Probabilistic Principal Component Analysis) or for hierarchical linear models!

The proof is straightforward:

Proof 6.45.4.

$$\begin{aligned}
&(A+UBV^T)\left[A^{-1}-A^{-1}U(B^{-1}+V^TA^{-1}U)^{-1}V^TA^{-1}\right]\\
&=\left[\mathbb{1}-U\left(B^{-1}+V^TA^{-1}U\right)^{-1}V^TA^{-1}\right]+\left[UBV^TA^{-1}-UBV^TA^{-1}U\left(B^{-1}+V^TA^{-1}U\right)^{-1}V^TA^{-1}\right]\\
&=\mathbb{1}+UBV^TA^{-1}-\left[U\left(B^{-1}+V^TA^{-1}U\right)^{-1}V^TA^{-1}+UBV^TA^{-1}U\left(B^{-1}+V^TA^{-1}U\right)^{-1}VA^{-1}\right]\\
&=\mathbb{1}+UBV^TA^{-1}-\left(U+UBV^TA^{-1}U\right)\left(B^{-1}+V^TA^{-1}U\right)^{-1}V^TA^{-1}]\\
&=\mathbb{1}+UBV^TA^{-1}-UB\left(B^{-1}+V^TA^{-1}U\right)\left(B^{-1}+V^TA^{-1}U\right)^{-1}V^TA^{-1}\\
&=\mathbb{1}+UBV^TA^{-1}-UBV^TA^{-1}=\mathbb{1}
\end{aligned} \tag{6.6.549}$$

■ Q.E.D.

Consider some special cases:

- If $U=V=\mathbb{1}$, then we get:

$$(A+B)^{-1}=A^{-1}-A^{-1}(A^{-1}+B^{-1})^{-1}A^{-1} \tag{6.6.550}$$

- If $B=\mathbb{1}$, and let $U=[\vec{u}_1,\ldots,\vec{u}_m]$ and $V=[\vec{v}_1,\ldots,\vec{v}_m]$, then we get the inverse of a rank-n modified matrix:

$$\left(A+UV^T\right)^{-1}=\left(A+\sum_{i=1}^{m}\vec{u}_i\vec{v}_i^T\right)^{-1}=A^{-1}-A^{-1}U\left(\mathbb{1}+V^TA^{-1}U\right)^{-1}V^TA^{-1} \tag{6.6.551}$$

- More specially, when $m=1$, $U=\vec{u}$ and $V=\vec{v}$ we get the inverse of rang-1 modified matrix:

$$(A+\vec{u}\vec{v}^T)^{-1}=A^{-1}-\frac{A^{-1}\vec{u}\vec{v}^TA^{-1}}{1+\vec{v}^TA^{-1}\vec{u}} \tag{6.6.552}$$

Let us see two possible derivations of that later case! First possible proof:

Proof 6.45.5. We first show the following is an identity ($A=\mathbb{1}$):

$$(\mathbb{1}+\vec{w}\vec{v}^T)^{-1}=\mathbb{1}-\frac{\vec{w}\vec{v}^T}{1+\vec{v}^T\vec{w}} \tag{6.6.553}$$

Pre-multiplying $\mathbb{1}+\vec{w}\vec{v}^T$, the right side becomes $\mathbb{1}$ as well as the left side:

$$\mathbb{1}+\vec{w}\vec{v}^T-\frac{\vec{w}\vec{v}^T+\vec{w}\vec{v}^T\vec{w}\vec{v}^T}{1+\vec{v}^T\vec{w}}=\mathbb{1}+\vec{w}\vec{v}^T-\frac{\vec{w}\left(1+\vec{v}^T\vec{w}\right)\vec{v}^T}{1+\vec{v}^T\vec{w}}=\mathbb{1}+\vec{w}\vec{v}^T-\vec{w}\vec{v}^T=\mathbb{1} \tag{6.6.554}$$

We next let $\vec{u}=A\vec{w}$ in:

$$(A+\vec{u}\vec{v}^T)^{-1}=A^{-1}-\frac{A^{-1}\vec{u}\vec{v}^TA^{-1}}{1+\vec{v}^TA^{-1}\vec{u}} \tag{6.6.555}$$

and the left side of the relation to be proven becomes:

$$\begin{aligned}\left(A+\vec{u}\vec{v}^T\right)^{-1}&=\left(A+A\vec{w}\vec{v}^T\right)^{-1}=\left(A\left(\mathbb{1}+\vec{w}\vec{v}^T\right)\right)^{-1}=\left(\mathbb{1}+\vec{w}\vec{v}^T\right)^{-1}A^{-1}\\&=\left(\mathbb{1}-\frac{\vec{w}\vec{v}^T}{1+\vec{v}^T\vec{w}}\right)A^{-1}\end{aligned} \tag{6.6.556}$$

Substituting $\vec{w}=A^{-1}\vec{u}$ we get the "Sherman-Morrison relation":

$$\left(A+\vec{u}\vec{v}^T\right)^{-1}=\left(\mathbb{1}-\frac{A^{-1}\vec{u}\vec{v}^T}{1+\vec{v}^TA^{-1}\vec{u}}\right)A^{-1}=A^{-1}-\frac{A^{-1}\vec{u}\vec{v}^TA^{-1}}{1+\vec{v}^TA^{-1}\vec{u}} \tag{6.6.557}$$

■ Q.E.D.

And second possible proof:

Proof 6.45.6. This second proof is based on the following problem. Assuming a linear equation system $A\vec{y}=\vec{b}$ is solve to get $\vec{y}=A^{-1}\vec{b}$, we want to solve this system:

$$(A+\vec{u}\vec{v}^T)\vec{x}=\vec{b} \tag{6.6.558}$$

We first pre-multiply both sides of this equation by A^{-1} to get:

$$A^{-1}\left(A+\vec{u}\vec{v}^T\right)\vec{x}=\left(\mathbb{1}+A^{-1}\vec{u}\vec{v}^T\right)\vec{x}=\vec{x}+A^{-1}\vec{u}\vec{v}^T\vec{x}=A^{-1}\vec{b}=\vec{y} \tag{6.6.559}$$

If we define $\vec{w}=A^{-1}\vec{u}$ and $\alpha=\vec{v}^T\vec{x}$, the above equation can be written as:

$$\vec{x}+\vec{w}\alpha=\vec{y} \tag{6.6.560}$$

Pre-multiplying both sides by $\vec{v}^T$, we get:

$$\vec{v}^T\vec{x}+\vec{v}^T\vec{w}\alpha=\vec{v}^T\vec{y},\qquad\text{i.e.}\qquad\alpha+\vec{v}^TA^{-1}\vec{u}\alpha=\vec{v}^T\vec{y} \tag{6.6.561}$$

Solving for α we get:

$$\alpha=\frac{\vec{v}^T\vec{y}}{1+\vec{v}^TA^{-1}\vec{u}} \tag{6.6.562}$$

Substituting α into the previous equation for $\vec{x}$ we get:

$$\vec{x}=\vec{y}-\vec{w}\alpha=\vec{y}-\frac{\vec{w}\vec{v}^T\vec{y}}{1+\vec{v}^TA^{-1}\vec{u}}=A^{-1}\vec{b}-\frac{A^{-1}\vec{u}\vec{v}^TA^{-1}\vec{b}}{1+\vec{v}^TA^{-1}\vec{u}}=\left(A^{-1}-\frac{A^{-1}\vec{u}\vec{v}^TA^{-1}}{1+\vec{v}^TA^{-1}\vec{u}}\right)\vec{b} \tag{6.6.563}$$

But solving the equation $(\vec{A}+\vec{u}\vec{v}^T)\vec{x}=\vec{b}$ we also get:

$$\vec{x}=(A+\vec{u}\vec{v}^T)^{-1}\vec{b} \tag{6.6.564}$$

we therefore have:

$$(A+\vec{u}\vec{v}^T)^{-1}=A^{-1}-\frac{A^{-1}\vec{u}\vec{v}^TA^{-1}}{1+\vec{v}^TA^{-1}\vec{u}} \tag{6.6.565}$$

6.7. Tensor Calculus

THE conventional vector calculus is a simple and effective technique that adapts perfectly to the study of mechanical and physical properties of matter in an Euclidean space of three dimensions. However, in many fields of physics, it appears experimental quantities that can't be easily represented by simple column vectors of Euclidean vector spaces. This is the case for example in continuum mechanics (fluids or solids), electromagnetism, General Relativity, etc.

Thus, since the late 119th century (holocene calendar), the analysis of forces acting within a continuous medium led to highlight the physical quantities characterized by nine numbers representing the pressure forces or internal stress (see section Continuum Mechanics page 3734 for the details). The representation of these quantities required the introduction of a new mathematical tool who was named "tensor", by reference to its physical origin. Subsequently, starting the years 11900s (holocene calendar), it was R. Ricci and T. Levi-Civita who developed the tensor calculus; then the study of tensor allowed a deepening of the theory of vector spaces and contributed to the development of differential geometry (see section of the same name page 2850).

Tensor calculus, also sometimes named "absolute differential geometry" also has the advantage to free itself from all coordinate systems and the results of the mathematical developments are thus invariant (huge simplification in calculations but in compensation we have a huge increase in abstraction and notation complexity). We therefore don't need to be concerned in what type of referential frame we work and this is very interesting in General Relativity.

We advise strongly the reader to very well master the basics of vector calculus and linear algebra as they have been presented before in previous sections (especially because linear algebra forms the skeleton of tensor calculus!). If necessary, we have chosen when writing this section to come back on certain points seen in the section of Vector Calculus and Linear Algebra (covariant components, contravariant components, etc.).

Furthermore, if the reader has already covered the study of constraints in solids (see section Continuum Mechanics page 3735) or of the Faraday tensor (see section Electrodynamics page 4121) or the energy-momentum tensor (see section General Relativity page 5754) this will be a practical advantage before reading what follows. Furthermore, the redaction of the above items (tensors) was made so that the concept of tensor is introduced if possible (...) intuitively.

We will only do a very few practical examples in this section. Indeed the examples, you have probably already guess it..., will come when we will study the continuum mechanics, General Relativity, quantum field theory, electrodynamics, etc.

A tip perhaps: you saw several times in the Statistics section that writing with vectors and then thinking with matrices was a powerful way to generalize certain important results. For this section on tensors, remember that the idea is the same but we write with matrices and we think with tensors (you will understand this little adage better once you have finished reading this entire section)!

6.7.1 Tensor

Definition (simplistic #263): The "tensors" are mathematical objects often wrongly represented (but this is for pedagogical reasons in engineering courses) as generalizing the notions of vectors and matrices. They were initially introduced in physics to represent the state of stress and deformation of a volume subjected to forces, hence their name (tensions).

The rigorous definition, on the other hand, requires (at least we personally think so...) having first read this section in its entirety. But for the impatient, know that in fact a tensor is roughly like the determinant of a square matrix (see section Linear Algebra page 1961) or like the dot product of vectors (see section Linear Algebra page 1821)... Yes! It is simply a multilinear map T on a space of given dimension (corresponding to the number of columns of the matrix/tensors) which finally gives a scalar (of a given field). For example in the bilinear case a tensor (then named "tensor of order 2") is defined by:

$$\begin{aligned}
&T(\vec{u},\vec{v})\in\mathbb{R}\\
&T(\lambda\vec{u},\mu\vec{v})=\lambda\mu T(\vec{u},\vec{v})\\
&T(\vec{u}+\vec{w},\vec{v})=T(\vec{u},\vec{v})+T(\vec{w},\vec{v})
\end{aligned}\tag{6.7.1}$$

For example for two vectors of dimension two we have in an orthonormal basis using the property of linearity and multiplication by a scalar of the definition of a tensor:

$$\begin{aligned}
T(\vec{u},\vec{v})&=T\left(u^x\vec{e}_x+u^y\vec{e}_y,v^x\vec{e}_x+v^y\vec{e}_y\right)\\
&=T\left(u^x\vec{e}_x,v^x\vec{e}_x+v^y\vec{e}_y\right)+T\left(u^y\vec{e}_y,v^x\vec{e}_x+v^y\vec{e}_y\right)\\
&=T\left(u^x\vec{e}_x,v^x\vec{e}_x\right)+T\left(u^x\vec{e}_x,v^y\vec{e}_y\right)+T\left(u^y\vec{e}_y,v^x\vec{e}_x\right)+T\left(u^x\vec{e}_y,v^y\vec{e}_y\right)\\
&=u^xv^x\underbrace{T(\vec{e}_x,\vec{e}_x)}_{T_{xx}=1}+u^xv^y\underbrace{\cancel{T(\vec{e}_x,\vec{e}_y)}}_{T_{xy}=0}+u^yv^x\underbrace{T(\vec{e}_y,\vec{e}_x)}_{T_{yx}=0}+u^yv^y\underbrace{T(\vec{e}_y,\vec{e}_y)}_{T_{yy}=1}\\
&=u^xv^x
\end{aligned}\tag{6.7.2}$$

And we see that we fall back on the expression of the dot product. And in practice it is unfortunately the matrix (in the bilinear case otherwise it is no longer a matrix!):

$$\begin{bmatrix}T_{xx}&T_{xy}\\T_{yx}&T_{yy}\end{bmatrix}$$

which is often wrongly named (for language simplification purposes in engineering courses) the "tensor" instead of the "matrix associated with the tensorial application T".

For example, we have proved in the section of Continuum Mechanics that normal and tangential forces in a fluid were given by the relation:

$$\begin{bmatrix}N_x\\N_y\\N_z\end{bmatrix}\begin{bmatrix}\sigma_{xx}&\tau_{xy}&\tau_{xz}\\\tau_{yx}&\sigma_{yy}&\tau_{yz}\\\tau_{zx}&\tau_{zy}&\sigma_{zz}\end{bmatrix}\begin{bmatrix}l\\m\\n\end{bmatrix}\tag{6.7.3}$$

what was noted in the traditional condensed form as following (where we no longer distinguish what is tangential to what is normal so there is a loss of clarity):

$$N_i=\sigma_{ij}n_j \tag{6.7.4}$$

We thus make appear a mathematical quantity σ_{ij} with 9 components, while a vector in the same space $\mathbb{R}^3$ has 3 components.

This notion is also much used in the section of General Relativity where we have proved that the energy-momentum tensor in a particularly simple case was given by:

$$T_{ij}=\begin{bmatrix} T^{00} & T^{01} & T^{02} & T^{03} \\ T^{10} & T^{11} & T^{12} & T^{13} \\ T^{20} & T^{21} & T^{22} & T^{23} \\ T^{30} & T^{31} & T^{32} & T^{33} \end{bmatrix}=\begin{bmatrix} \rho\gamma^2c^2 & \rho\gamma^2cv^x & \rho\gamma^2cv^y & \rho\gamma^2cv^z \\ \rho\gamma^2cv^x & \rho\gamma^2v^xv^x & \rho\gamma^2v^xv^y & \rho\gamma^2v^xv^z \\ \rho\gamma^2cv^y & \rho\gamma^2v^yv^x & \rho\gamma^2v^yv^y & \rho\gamma^2v^yv^z \\ \rho\gamma^2cv^z & \rho\gamma^2v^zv^x & \rho\gamma^2v^zv^y & \rho\gamma^2v^zv^z \end{bmatrix} \tag{6.7.5}$$

and satisfies the non-less important equation of conservation:

$$\nabla_\mu T^{\mu\nu}=0 \tag{6.7.6}$$

Or otherwise, still in the section of General Relativity, we have shown that the tensor of the Schwarzschild metric was given by:

$$g^{\mu\nu}=\begin{bmatrix} 1/A(r) & 0 & 0 & 0 \\ 0 & -1/B(r) & 0 & 0 \\ 0 & 0 & -1/r^2 & 0 \\ 0 & 0 & 0 & -1/(r^2\sin^2(\theta)) \end{bmatrix} \tag{6.7.7}$$

and therefore gives us the "equation of the metric" or "invariant interval" (see section Special Relativity page 5704):

$$\mathrm{d}s^2=g_{\mu\nu}\mathrm{d}x^\mu\mathrm{d}x^\nu \tag{6.7.8}$$

Note also that in the section of Special Relativity we have shown that the Lorentz transformation tensor is given by:

$$\begin{pmatrix} x'^0 \\ x'^1 \\ x'^2 \\ x'^3 \end{pmatrix}=\begin{bmatrix} \gamma & -\gamma\beta & 0 & 0 \\ -\gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}\begin{pmatrix} x^0 \\ x^1 \\ x^2 \\ x^3 \end{pmatrix} \tag{6.7.9}$$

which in a condensed form gives the following components transformation:

$$x'^\mu=L^\mu_\nu x^\nu \tag{6.7.10}$$

As regards the transformation of the electromagnetic field we have also proved that the Faraday tensor is given by:

$$F^{\mu\nu}=\begin{bmatrix} 0 & -E_x & -E_y & -E_z \\ E_x & 0 & -B_z & B_y \\ E_y & B_z & 0 & -B_x \\ E_z & -B_y & B_x & 1 \end{bmatrix} \tag{6.7.11}$$

and therefore permits switch from one repository frame to another using the relation:

$$F'^{\mu\nu}=L_{\alpha}^{\mu}L_{\beta}^{\nu}F^{\alpha\beta} \tag{6.7.12}$$

But these are very simple tensor that can be represented in the form of matrices. You should also remember that it is not because you are reading a variable with indices suggests that we are dealing with a tensor that it is necessarily one. For example, the famous relation (widely used in the section of General Relativity and we will prove far further below):

$$\Gamma_{kj}^{i}=g^{il}\Gamma_{klj}=\frac{1}{2}g^{il}\left(\partial_k g_{lj}+\partial_j g_{kl}-\partial_l g_{kj}\right) \tag{6.7.13}$$

might suggest that the first member of the far left is a tensor but in fact it is not... this is just a symbol... hence its name: Christoffel symbol (not: Christoffel tensor).

The interest of tensors in physics is that their characteristics are independent of the chosen coordinates. Thus, a relation between tensors in a base will be true regardless of the base used thereafter. This is a fundamental and powerful characteristic of General Relativity (among others)!

6.7.2 Indicial Notation

We will use thereafter many mathematical symbols: coordinates, components of vectors and tensors, matrix components, etc., whose number in each category is large or indeterminate. To distinguish the various symbols of a category we use indices. For example, instead of the traditional variables x, y, z we will use the variables x_1, x_2, x_3 (as we have already done in the section of Linear Algebra). This rating becomes essential when we an undetermined number of variables.

Thus, if we have n variables, we denote them by $x_1, x_2, \ldots, x_n$.

We will also use superscripts, when required; eg x^1, x^2, x^3. To avoid confusion with writing powers, the quantity x^i to the power p will be written $(x^i)^p$. When the context eliminates any potential ambiguity, the use of parentheses however is not fundamentally necessary.

In tensor calculus there is a summation convention using the fact that the repeated index, below for example the index i, will become itself an indication of the summation. We write then, with this convention:

$$\sum_{i=1}^{n} x^i y^i = x^i y^i = x^1 y^1 + x^2 y^2 + \ldots + x^n y^n \tag{6.7.14}$$

thereby this condense relatively well the notations!

Thus, to represent the linear system:

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 &= b_2 \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 &= b_3 \end{aligned} \tag{6.7.15}$$

we will write (notice carefully how are written the components of the associated matrix!):

$$a_{ij}x_j = b_i \tag{6.7.16}$$

specifying that's for $n = 3$.

We see in this example, how the summation convention allows a condensed and thus powerful writing.

The summation convention covers all the mathematical symbols having repeating indices. Thus the decomposition of a vector $\vec{x}$ on a basis $(\vec{e}_1, \vec{e}_2, \vec{e}_3)$ will be therefore written for $n = 3$:

$$\vec{x} = x_1\vec{e}_1 + x_2\vec{e}_2 + x_3\vec{e}_3 = x^i\vec{e}_i \tag{6.7.17}$$

In summary, any term that has a repeated index represents a sum over all possible values of the repeated index.

Remark

We name, for obvious reasons we will detail below, the x^i "contravariant component" of the vector $\vec{x}$.

6.7.2.1 Summation on multiple index

The summation convention (due to Einstein) extends to the case where we have, in general, several repeated indices in upper and lower positions so-named "dumb indices" in the same monomial (often physicists omit the rule of set their position opposite as it will be the case often on this textbook too!). Thus, for example, the quantity $A_i^j x^i x^j$, represents the following sum for i and j taking the values from 1 to 2:

$$A_i^j x^i x^j = A_1^1 x^1 x^1 + A_2^1 x^1 x^2 + A_1^2 x^2 x^1 + A_2^2 x^2 x^2 \qquad (6.7.18)$$

Thus we see easily that an expression with two summation indices that take values respectively $1, 2, \ldots, n$, will have n^2; n^3 if there are three summation indices, etc.

However, we must be careful to substitutions with this kind of notation because if we assume that we have the relation:

$$A = a_{ij} x^i y_j \quad \text{and} \quad x^i = c_{ij} y^j \qquad (6.7.19)$$

then to get the expression of A only in function of the variables y^j we cannot write:

$$A = a_{ij} c_{ij} y^i y_j \qquad (6.7.20)$$

because it does not return to the same expression as the dumb indices after development are systematically sum in an identical and rigid way (we leave to the reader make a little application case to see this, if need you can contact us and we will do an example). In other words, a dumb index can not be repeated more than 2 times.

6.7.2.2 Kronecker Symbol

This symbol introduced by the mathematician Kronecker, is the following (often used in physics and in many other fields):

$$\delta_{ij} = \delta^{ij} = \delta_i^j = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases} \qquad (6.7.21)$$

This symbol is named "Kronecker symbol". It conveniently allows you to write, for example, the dot product of two vectors $\vec{e}_1$ and $\vec{e}_2$, of unit norm and orthogonal to each other, in the form:

$$\vec{e}_i \circ \vec{e}_j = \delta_{ij} \qquad (6.7.22)$$

We will find this symbol in many examples of theoretical physics in this textbook (wave quantum physics, quantum field theory, general relativity, fluid mechanics, etc.).

It should be noted that there is a generalized version of the Kronecker symbol:

$$\delta_{mn..p}^{ij..l} = \begin{bmatrix} \delta_m^i & \delta_n^i & \cdots & \delta_p^i \\ \delta_m^j & \delta_n^j & \cdots & \delta_p^j \\ \vdots & \vdots & \ddots & \vdots \\ \delta_m^l & \delta_n^l & \cdots & \delta_p^l \end{bmatrix} \qquad (6.7.23)$$

We have also, for example:

$$\delta^{ijk}_{mnp}=\begin{bmatrix}\delta^i_m & \delta^i_n & \delta^i_p\\ \delta^j_m & \delta^j_n & \delta^j_p\\ \delta^k_m & \delta^k_n & \delta^k_p\end{bmatrix}=\varepsilon^{ijk}\varepsilon_{mnp} \qquad (6.7.24)$$

where ε_{ijk} is the Levi-Civita symbol that will define right now:

6.7.2.3 Antisymmetric Symbol (Levi-Civita symbol)

Another useful symbol is the "symbol of antisymmetry" or also named "antisymmetry tensor" that we will find in the sections of Electrodynamics, General Relativity and Relativistic Quantum Physics in this textbook.

In mathematics, particularly in linear algebra, tensor analysis, and differential geometry, the Levi-Civita symbol represents a collection of numbers; defined from the sign of a permutation of the natural numbers $1,2,\ldots,n$, for some positive integer n.

The values of the Levi-Civita symbol are independent of any metric tensor and coordinate system. Also, the specific term "symbol" emphasizes that it is not a tensor because of how it transforms between coordinate systems, however it can be interpreted as an antisymmetric tensor (a tensor is antisymmetric on (or with respect to) an index subset if it alternates sign (+/-) when any two indices of the subset are interchanged).

In the case $n=2$ the Levi-Civita symbol is defined by:

$$\varepsilon_{ij}=\begin{cases}+1 & \text{if } (i,j) \text{ is } (1,2)\\ -1 & \text{if } (i,j) \text{ is } (2,1)\\ 0 & \text{if } i=j\end{cases} \qquad (6.7.25)$$

The values can be arranged into a 2×2 antisymmetric matrix (we can see we fall back on the definition of an antisymmetric tensor):

$$\begin{pmatrix}\varepsilon_{11} & \varepsilon_{12}\\ \varepsilon_{21} & \varepsilon_{22}\end{pmatrix}=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix} \qquad (6.7.26)$$

Use of the 2D symbol is relatively uncommon, although in certain specialized topics like supersymmetry and twistor theory it appears in the context of 2-spinors. The 3D and higher-dimensional Levi-Civita symbols are used more commonly.

In three dimensions, the Levi-Civita symbol is defined as follows:

$$\varepsilon_{ijk}=\begin{cases}+1 & \text{if } (i,j,k) \text{ is } (1,2,3),(2,3,1) \text{ or } (3,1,2),\\ -1 & \text{if } (i,j,k) \text{ is } (3,2,1),(1,3,2) \text{ or } (2,1,3),\\ 0 & \text{if } i=j \text{ or } j=k \text{ or } k=i\end{cases} \qquad (6.7.27)$$

i.e. ε_{ijk} is 1 if (i,j,k) is an even permutation of $(1,2,3)$ or in the natural order $(1,2,3)$, -1 if it is an odd permutation, and 0 if any index is repeated. In three dimensions only, the cyclic permutations of $(1,2,3)$ are all even permutations, similarly the anti-cyclic permutations are all odd permutations. This means in 3D it is sufficient to take cyclic or anti-cyclic permutations of $(1,2,3)$ and easily obtain all the even or odd permutations.

It can also be express with the Kronecker symbol:

$$\varepsilon_{ijk}=\begin{bmatrix}\delta_{i1} & \delta_{i2} & \delta_{i3}\\ \delta_{j1} & \delta_{j2} & \delta_{j3}\\ \delta_{k1} & \delta_{k2} & \delta_{k3}\end{bmatrix} \tag{6.7.28}$$

An illustrative representation gives:

$$\varepsilon_{ijk}=$$

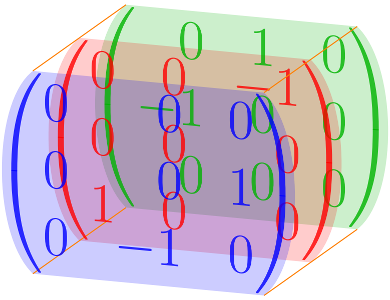

Figure 6.154: **3D Levy-Civita symbol illustration**

By using this symbol, a determinant of order two (see section Linear Algebra page 1961) is then written in the advantageous form:

$$\det(A)=\det(a_{ij})=\varepsilon_{ij}a_1^ia_2^j \tag{6.7.29}$$

and the vector cross product:

$$\boxed{\vec{x}\times\vec{y}=\varepsilon_{ijk}x_jy_k} \tag{6.7.30}$$

where of course, j and k are summed and where the dummy index i is the line number of the resulting vector (if requested we will make the developments). In particular, the rotational (curl) of a vector field (see section Vector Calculus page 1888) is then:

$$\boxed{\vec{\nabla}\times\vec{A}=\varepsilon_{ijk}\frac{\partial A_k}{\partial x_j}=\varepsilon_{ijk}\partial_jA_k} \tag{6.7.31}$$

As an example, let us calculate in index notation the double vector product $\vec{A}\times\vec{B}\times\vec{C}$:

$$\begin{aligned}\vec{A}\times\vec{B}\times\vec{C}&=\varepsilon_{ijk}\varepsilon_{kmn}A_jB_mC_n=(\delta_{im}\delta_{jn}-\delta_{in}\delta jm)A_jB_mC_n=B_i(A_jC_j)-C_i(A_jB_j)\\&=\vec{B}(\vec{A}\circ\vec{C})-\vec{C}(\vec{A}\circ\vec{B})\end{aligned} \tag{6.7.32}$$

where again, the dummy index i is the line number of the resulting vector. Let us see detailed demonstration of these equalities (the order of the equalities below does not need to follow the sequence of equalities of the previous relation).

Proof 6.45.7. We have proved in the section of Vector Calculus the following identity:

$$\vec{A}\times\vec{B}\times\vec{C}=\vec{B}(\vec{A}\circ\vec{C})-\vec{C}(\vec{A}\circ\vec{B}) \tag{6.7.33}$$

Remark

The latter relation is sometimes, and for recall, named the "Grassmann rule" or more commonly "dual vector product".

To prove the relation:

$$\vec{A}\times\vec{B}\times\vec{C}=\varepsilon_{ijk}\varepsilon_{kmn}A_jB_mC_n \tag{6.7.34}$$

to a change of indices let us first prove that:

$$(\vec{B}\times\vec{C})_i=\varepsilon_{ijk}B_jC_k \tag{6.7.35}$$

which give us:

$$\begin{pmatrix}B_2C_3-B_3C_2\\B_3C_1-B_1C_3\\B_1C_2-B_2C_1\end{pmatrix}=\begin{pmatrix}\varepsilon_{1jk}B_jC_k\\\varepsilon_{2jk}B_jC_k\\\varepsilon_{3jk}B_jC_k\end{pmatrix} \tag{6.7.36}$$

We do the development only for the first line (this is already bor... euh long enough...):

$$\begin{aligned}&B_2C_3-B_3C_2=\varepsilon_{1jk}B_jC_k=\varepsilon_{11k}B_1C_k+\varepsilon_{12k}B_2C_k+\varepsilon_{13k}B_3C_k\\&=\varepsilon_{111}B_1C_1+\varepsilon_{112}B_1C_2+\varepsilon_{113}B_1C_3+\varepsilon_{121}B_2C_1+\varepsilon_{122}B_2C_2+\varepsilon_{123}B_2C_3+\varepsilon_{131}B_3C_1\\&+\varepsilon_{132}B_3C_2+\varepsilon_{133}B_3C_3=\varepsilon_{123}B_2C_3+\varepsilon_{132}B_3C_2=1B_2C_3-1B_3C_2=B_2C_3-B_3C_2\end{aligned} \tag{6.7.37}$$

This is the first step that was necessary to be proven.

Now let us prove that for the nth line we have well:

$$(\vec{A}\times(\vec{B}\times\vec{C})_i)_l=\varepsilon_{lni}A_n(\varepsilon_{ijk}B_jC_k)_i \tag{6.7.38}$$

with the help of a result obtained in the section of Vector Calculus (vector product of three different vectors) we have the first term (the first line of the vector resulting from the calculation):

$$\begin{aligned}&(A_2(B_1C_2-B_2C_1)_3-A_3(B_3C_1-B_1C_2)_2)_1=\varepsilon_{1ni}A_n(\varepsilon_{ijk}B_jC_k)_i\\&=\varepsilon_{1n1}A_n(B_2C_3-B_3C_2)_1+\varepsilon_{1n2}A_n(B_3C_1-B_1C_3)_2+\varepsilon_{1n3}A_n(B_1C_2-B_2C_1)_3\\&=\varepsilon_{111}A_1(B_2C_2-B_3C_2)_1+\varepsilon_{121}A_2(B_2C_2-B_3C_2)_1+\varepsilon_{131}A_3(B_2C_3-B_3C_2)_1\\&+\varepsilon_{112}A_1(B_3C_1-B_1C_3)_2+\varepsilon_{122}A_2(B_3C_1-B_1C_3)_2+\varepsilon_{132}A_3(B_3C_1-B_1C_3)_2\\&+\varepsilon_{113}A_1(B_1C_2-B_2C_1)_3+\varepsilon_{123}A_2(B_1C_2-B_2C_1)_3+\varepsilon_{133}A_3(B_1C_2-B_2C_1)_3\\&=\varepsilon_{123}A_2(B_1C_2-B_2C_1)_3+\varepsilon_{132}A_3(B_3C_1-B_1C_3)_2\\&=1A_2(B_1C_2-B_2C_1)_3-1A_3(B_3C_1-B_1C_3)_2=A_2(B_1C_2-B_2C_1)-A_3(B_3C_1-B_1C_3)\end{aligned} \tag{6.7.39}$$

It is immediate that (i being equal to 1):

$$\begin{aligned}&\vec{A}\times\vec{B}\times\vec{C}=(\vec{A}\times\vec{B}\times\vec{C})_i=B_i(A_jC_j)-C_i(A_jB_j)=\\&=B_1(A_1C_1+A_2C_2+A_3C_3)-C_1(A_1B_1+A_2B_2+A_3B_3)\\&=B_1A_1C_1+B_1A_2C_2+B_1A_3C_3-C_1A_1B_1-C_1A_2B_2-C_1A_3B_3\\&=A_2B_1C_2-A_2B_2C_1-A_3B_3C_1+A_3B_1C_3\\&=A_2(B_1C_2-B_2C_1)-A_3(B_3C_1-B_1C_3)\end{aligned} \tag{6.7.40}$$

Let us show now that for i equal 1 we also have:

$$\begin{aligned}\vec{A}\times\vec{B}\times\vec{C}&=(\vec{A}\times\vec{B}\times\vec{C})_i=(\delta_{im}\delta_{jn}-\delta_{in}\delta_{jm})A_jB_mC_n\\&=A_2(B_1C_2-B_2C_1)-A_3(B_3C_1-B_1C_3)\end{aligned}\tag{6.7.41}$$

Indeed:

$$\begin{aligned}&(\vec{A}\times\vec{B}\times\vec{C})_1=(\delta_{1m}\delta_{jn}-\delta_{1n}\delta_{jm})A_jB_mC_n\\&=(\delta_{1m}\delta_{j1}-\delta_{11}\delta_{jm})A_jB_mC_1+(\delta_{1m}\delta_{j2}-\delta_{12}\delta_{jm})A_jB_mC_2+(\delta_{1m}\delta_{j3}-\delta_{13}\delta_{jm})A_jB_mC_3\\&=(\delta_{1m}\delta_{11}-\delta_{11}\delta_{1m})A_1B_mC_1+(\delta_{1m}\delta_{21}-\delta_{11}\delta_{2m})A_2B_mC_1+(\delta_{1m}\delta_{31}-\delta_{11}\delta_{3m})A_3B_bC_1\\&+(\delta_{1m}\delta_{12}-\delta_{12}\delta_{1m})A_1B_mC_2+(\delta_{1m}\delta_{22}-\delta_{12}\delta_{2m})A_2B_mC_2+(\delta_{1m}\delta_{32}-\delta_{12}\delta_{3m})A_3B_mC_2\\&+(\delta_{1m}\delta_{13}-\delta_{13}\delta_{1m})A_1B_mC_3+(\delta_{1m}\delta_{23}-\delta_{13}\delta_{2m})A_2B_mC_2+(\delta_{1m}\delta_{33}-\delta_{13}\delta_{3m})A_3B_mC_3\\&=(\delta_{1m}-\delta_{1m})A_1B_mC_1-\delta_{2m}A_2B_mC_1-\delta_{3m}A_3B_mC_1+\delta_{1m}A_2B_mC_2+\delta_{1m}A_3B_mC_3\\&=-\delta_{2m}A_2B_mC_1-\delta_{3m}A_3B_mC_1+\delta_{1m}A_2B_mC_2+\delta_{1m}A_3B_mC_3\\&=\delta_{21}A_2B_1C_1-\delta_{22}A_2B_2C_1-\delta_{23}A_2B_3C_1-\delta_{31}A_3B_1C_1-\delta_{32}A_3B_2C_1-\delta_{33}A_3B_3C_1\\&+\delta_{11}A_2B_1C_2+\delta_{21}A_2B_2C_2+\delta_{13}A_2B_3C_2+\delta_{11}A_3B_1C_3+\delta_{12}A_3B_2C_3+\delta_{13}A_3B_3C_3\\&=-A_2B_2C_1-A_3B_3C_1+A_2B_1C_2+A_2B_1C_3=A_2(B_1C_2-B_2C_1)-A_3(B_3C_1-B_1C_3)\end{aligned}\tag{6.7.42}$$

■ Q.E.D.

As a second example, let us prove that the divergence of a curl vanishes:

$$\vec{\nabla}\circ(\vec{\nabla}\times\vec{A})=\partial_i(\varepsilon_{ijk}\partial_jA_k)=\varepsilon_{ijk}\partial_i\partial_jA_k\tag{6.7.43}$$

By the Schwarz's theorem (see section Differential and Integral Calculus page 1469) $\partial_i\partial_j$ is symmetric (so invert the indices has no impact) in the indices and that ε_{ijk} is antisymmetric (by definition) in the same indices, the sum on i and j must necessarily cancel. For example, the contribution to the sum of the $i=1, j=2$ is the opposite of this with $i=2, j=1$.

Remarks

R1. The symbol of antisymmetry is often named "Levi-Civita tensor" in the literature. In fact, although it is a tensor in the form of its notation, it's more of a mathematical tool that a mathematical "being" hence the preference of some physicists to name it "symbol" rather than "tensor". But it's up to you ...

R2. By abuse of writing we do not write the basic vector but rigorously, and to avoid forgetting it, remember that in order to balance the members of the equality and in order to clarify that the vectors are expressed in the same base, we should write:

$$\vec{A}\times\vec{B}=\varepsilon_{ijk}A_jB_k\vec{e}_i\qquad\vec{\nabla}\times\vec{A}=\varepsilon_{ijk}\partial_jA_k\vec{e}_i\tag{6.7.44}$$

Let us now see the first simple practical applications of this index notation using the example of the base change that we have seen in the section of Vector Calculus:

Given two bases $(\vec{e}_1,\vec{e}_2,\ldots,\vec{e}_n)$ and $(\vec{e}_1',\vec{e}_2',\ldots,\vec{e}_n')$ of an Euclidean vector space $\mathcal{E}^n$. Each vector of a base can be decomposed on the other base in the form of a linear application (base change matrix - see section Linear Algebra page 1992):

$$\vec{e}_i = A'^k_i \vec{e}'_k \qquad \text{and} \qquad \vec{e}'_k = A^i_k \vec{e}_i \tag{6.7.45}$$

where we obviously use the summation convention for $i,k=1,2,\ldots,n$.

Let us recall that the base change matrix (or "transformation matrix") should have as many columns as the basic vector have lines (dimensions or components). Small example with three dimensions gives:

$$\begin{pmatrix} x'_1 \\ x'_2 \\ x'_3 \end{pmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \begin{bmatrix} x_1a_{11}+x_2a_{12}+x_3a_{13} \\ x_2a_{21}+x_2a_{22}+x_3a_{23} \\ x_1a_{31}+x_2a_{32}+x_3a_{33} \end{bmatrix} \tag{6.7.46}$$

and obviously it is much more funny to write this as:

$$x'_i = A^k_i x_k \tag{6.7.47}$$

so where on A, we have the k that represents the column of the matrix and i the row of the matrix.

Any vector $\vec{x}$ of $\mathcal{E}^n$ can be decomposed (we have already prove this in the section of Vector Calculus) on each basis $\mathcal{E}^n$ under the form:

$$\vec{x} = x^i \vec{e}_i = x'^k \vec{e}'_k \tag{6.7.48}$$

If we seek for the relations between the components x^i and x'^k it is enough to take again the relations prove in the section of Linear Algebra and we have then:

$$\vec{x} = x^i \vec{e}_i = x^i A'^k_i \vec{e}'_k = x'^k A^i_k \vec{e}_i \tag{6.7.49}$$

Immediately by the uniqueness of the decomposition of a vector on a base, we can equalize the components of the basis vectors and we get (the must be careful to rearrange again the order of the terms because the matrix multiplication is in general, not commutative as we already know!):

$$x'^k = A'^k_i x^i \quad \text{and} \quad x^i = A^i_k x'^k \tag{6.7.50}$$

By construction we also have the trivial relation:

$$A'^i_k A^j_i = \delta^j_k \tag{6.7.51}$$

As:

$$x^i = A^i_k x'^k = A^i_k (A'^k_i x^i) = (A^i_k A'^k_i) x^i \tag{6.7.52}$$

A way to prove in a quite general way the previous relation using tensor calculus notation is to remember the following result proved in the section of Linear Algebra:

$$\vec{x} = x^i \vec{e}_i = x^j A'^k_i = \vec{e}'_k = x'^k \vec{e}'_k = x'^k A^i_k \vec{e}_i \tag{6.7.53}$$

and by using:

$$\vec{e}'_k = A^i_k \vec{e}_i \tag{6.7.54}$$

We therefore have:

$$\vec{e}_i = A'^k_i \vec{e}'_k = A'^k_i A^j_k \vec{e}_j \tag{6.7.55}$$

The basis vectors being linearly independent, this last relation implies that when $i \neq j$:

$$A'^k_i A^j_k = 0 \tag{6.7.56}$$

and when $i = j$:

$$A'^k_i A^j_k = 1 \tag{6.7.57}$$

Therefore it comes:

$$A'^k_i A^j_k = \delta^j_i \tag{6.7.58}$$

And for the dot product, the results obtained with the index notation are very interesting and extremely powerful. We have already defined the scalar product in the section of Vector Calculus (see page 1821) but let us see how we handle this with the index notation!

Let us consider an Euclidean vector space $\mathcal{E}^n$ reported any basis $\vec{e}_i$. We already know that vectors are written on this basis:

$$\vec{x} = x^i \vec{e}_i \qquad \vec{y} = y^i \vec{e}_j \tag{6.7.59}$$

The scalar product with respect to its properties and the index notation is then written:

$$\boxed{\vec{x} \circ \vec{y} = (x^i \vec{e}_i) \circ (y^i \vec{e}_j) = x^i y^j (\vec{e}_i \circ \vec{e}_j) = g_{ij} x^i y^j} \tag{6.7.60}$$

This is a fundamental relation for advanced physics (General Relativity and String Theory) that makes appear the "metric covariant tensor" (see section Non-Euclidean Geometry page 2673):

$$\boxed{g_{ij} = \vec{e}_i \circ \vec{e}_j} \tag{6.7.61}$$

and to satisfy the commutative property of the dot product (see section Vector Calculus page 1821) we must obviously have the equality (at least in Euclidean space or approximated as...):

$$g_{ij} = g_{ji} \tag{6.7.62}$$

The prior-previous relation is sometimes written in the form:

$$[g] = \begin{bmatrix} g_{11} & g_{12} & \cdots & g_{1n} \\ g_{21} & g_{22} & \cdots & g_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ g_{m1} & g_{m2} & \cdots & g_{mn} \end{bmatrix} = \begin{bmatrix} \vec{e}_1 \circ \vec{e}_1 & \vec{e}_1 \circ \vec{e}_2 & \cdots & \vec{e}_1 \circ \vec{e}_n \\ \vec{e}_2 \circ \vec{e}_1 & \vec{e}_2 \circ \vec{e}_2 & \cdots & \vec{e}_2 \circ \vec{e}_n \\ \vdots & \vdots & \ddots & \vdots \\ \vec{e}_m \circ \vec{e}_1 & \vec{e}_m \circ \vec{e}_2 & \cdots & \vec{e}_m \circ \vec{e}_n \end{bmatrix} \tag{6.7.63}$$

Remark

When the basis vectors $\vec{e}_i$ form an orthogonal vector space (not necessarily orthonormal) the quantities:

$$g_{ij}=\vec{e}_i\circ\vec{e}_j \quad (6.7.64)$$

are obviously zero when $i\neq j$. The dot product of two vectors $\vec{x}$ and $\vec{y}$ is then reduce to:

$$\vec{x}\circ\vec{y}=g_{11}x^1y^1+g_{22}g^2y^2+\ldots+g_{nn}x^ny^n \quad (6.7.65)$$

We then have in this particular case:

$$g_{ij}=\delta_{ij}(\vec{e}_i\circ\vec{e}_j) \quad (6.7.66)$$

and therefore when the basis vectors form an orthonormal vector space it is clear that g_{ij} is equal to the Kronecker symbol alone such that:

$$\vec{x}\circ\vec{y}=\|\vec{x}\circ\vec{y}\|^2=\delta_{ij}x^iy^j \quad (6.7.67)$$

6.7.3 Metric and Signature

As we have seen in it in the section of Vector Calculus (and Topology), the dot product of a vector $\vec{x}$ can be used to define the concept of norm of a vector (and also the concept of distance).

Let us recall that we have by definition the norm of a vector which is given by (see section Vector Calculus page 1821):

$$\vec{x}\circ\vec{x}=g_{ij}x^ix^j=\|\vec{x}\|^2 \quad (6.7.68)$$

where the numbers g_{ij} define somehow a "measure" of the vectors; we then say in the language of tensor calculus that they are the "metrics" of the selected vector space.

In the space of classical geometry, the norm is a number that is always strictly positive and which becomes zero if the measured vector is also zero. By cons the previous expression of the norm of a vector, may eventually be negative for any numbers $g_{11},g_{12},\ldots,g_{nn}$ (complex spaces for example). So we can distinguish two kinds pre-Euclidean vector spaces (Euclidean space in which we define a scalar product for recall) depending on the fact that the norm is positive or not. However when in theoretical physics we want to make the analogy with a vector space structure we need that the condition:

$$g=\det[g_{ij}]\neq 0 \quad (6.7.69)$$

is satisfied (g_{ij} can be written as a matrix, nothing prevents us to do it).

Explanations: We know that the dot product must satisfy the commutative property such that:

$$\vec{x}\circ\vec{y}=g_{ij}x^iy^j=\vec{y}\circ\vec{x}=g_{ji}x^jy^i \quad (6.7.70)$$

On the other hand, if for any non-zero y^j we have:

$$g_{ij}x^iy^j=0 \quad (6.7.71)$$

this implies $x^i=0$ (that is one of the properties of the norm we saw in the section of Vector Calculus). We can then write:

$$g_{ij}x^i=0 \tag{6.7.72}$$

We are here simply with a system of n equations with n unknowns (having to admit by hypothesis that only the solution $x^i=0$), it is necessary and sufficient for this that the determinant of the system, denoted g, to be is different from zero (see section Linear Algebra page 1980). So we must have:

$$g=\det[g_{ij}]\neq 0 \tag{6.7.73}$$

It is one of the condition for an expression comparable to a norm under a tensor index notation form in the context of theoretical physics vector space of the states of the system !!

Remarks

R1. The number of $+$ and $-$ signs found in the expression of the dot product is a is a characteristic of a given vector space E^n. It is named the "signature of the vector space".

R2. A practical application of calculation of the metric is presented in details in the section of General Relativity.

From the coefficients of the covariant metric tensor g_{ij} defining the metric of the space E^n, we can introduce the coefficients of the "contravariant metric tensor g^{ij}" defining the metric of a "dual space" E_*^n by the relation:

$$\boxed{g_{ik}g^{kj}=\delta_i^j=\begin{cases}1 & \text{if } i=j\\ 0 & \text{if } i\neq j\end{cases}} \tag{6.7.74}$$

In other words, the metric tensor twice covariant is its own inverse by its equivalent twice contravariant tensor. We will prove it explicitly later by showing during our study of the of the Gram's determinant that contravariant and covariant components of a Euclidean space are equal and both space have the same number of dimensions.

A well known special case that meets the above equality is the Minkowski's metric tensor of (see section Special Relativity page 5705), where we have:

$$\eta_{\mu\nu}=\eta^{\mu\nu}=\begin{bmatrix}1 & 0 & 0 & 0\\ 0 & -1 & 0 & 0\\ 0 & 0 & -1 & 0\\ 0 & 0 & 0 & -1\end{bmatrix} \tag{6.7.75}$$

Remark

The space E^n is also named "primal space" and if it is of Euclidean type let us recall that it is denoted $\mathcal{E}^n$.

The dual space is underpinned by n basis vectors $\vec{e}^{\,i}$ constructed from the vectors $\vec{e}_i$ such that:

$$\boxed{\vec{e}^{\,i}=g^{ij}\vec{e}_j} \tag{6.7.76}$$

It is therefore easy to see that the scalar product of the vectors $\vec{e}^i$ defines the metric g^{ij} of the dual space:

$$\vec{e}^i \circ \vec{e}^j = (g^{ik}\vec{e}_k) \circ (g^{jl}\vec{e}_l) = g^{ik}g^{jl}(\vec{e}_k \circ \vec{e}_l) = g^{ik}(g^{jl}g_{kl}) = g^{ik}\delta_k^j = g^{ij} \qquad (6.7.77)$$

while the vectors $\vec{e}^i$ (contravariant) and $\vec{e}_j$ (covariates) are orthogonal:

$$\vec{e}^i \circ \vec{e}_j = (g^{ik}\vec{e}_k) \circ \vec{e}_j = g^{ik}(\vec{e}_k \circ \vec{e}_j) = g^{ik}g_{kj} = \delta_j^i \qquad (6.7.78)$$

We can also express a vector in the dual base by the next writing by noting that obviously the position of the dummy indices is reversed:

$$\vec{x} = x_1\vec{e}^1 + x_2\vec{e}^2 + x_3\vec{e}^3 = x_i\vec{e}^i \qquad (6.7.79)$$

Remark

The components x_i (orthogonal projections of the vector on the axes) are named, for reasons that we will see further below, the "covariant" components.

So we finally have the possibility to change the vectors of a base to another one:

$$\vec{x} = x_i\vec{e}^i = x_i(g^{ik}\vec{e}_k) = (x_i g^{ik})\vec{e}_k = x^k\vec{e}_k \qquad (6.7.80)$$

where it is important to remember that to make a contravariant a covariant component, we bring up the index:

$$\boxed{x^k = g^{ik}x_i} \qquad (6.7.81)$$

and conversely, to make it covariant:

$$\boxed{x_i = g_{ik}x^k} \qquad (6.7.82)$$

A "covariant vector" or "cotangent vector" (often abbreviated as "covector") has components that co-vary with a change of basis. That is, the components must be transformed by the same matrix as the change of basis matrix. The components of covectors (as opposed to those of vectors) are said to be "covariant".

So, still in the case of the example of the Minkowski metric, if we consider the contravariant four-vector:

$$x^\mu = (x^0, x^i) = (x^0, \vec{x}) \qquad (6.7.83)$$

Then we have:

$$x_\mu = \eta_{\mu\nu}x^\nu = \eta_{\mu\nu}(x^0, \vec{x}) = (x_0, -x_i) = (x_0, -\vec{x}) \qquad (6.7.84)$$

6.7.4 Gram's Determinant

Let us see another approach to determine the base vectors of the dual space that can allow also a better understanding of the concept and will allow us to get an interesting result that we will use during certain calculations of General Relativity and String Theory (mainly its study using to the Lagrangian formalism).

So we have for $i=j=1$:

$$\vec{e}^{\,1}\circ\vec{e}_1=1 \tag{6.7.85}$$

This scalar product can be seen as a normalization condition for the two bases and two scalar products $\vec{e}^{\,2}\circ\vec{e}_1=0, \vec{e}^{\,2}\circ\vec{e}_1=0$ as orthogonalization conditions. Thus, as $\vec{e}_1$ is perpendicular to $\vec{e}^{\,2},\vec{e}^{\,3}$ we can write:

$$\vec{e}^{\,1}=c^{te}(\vec{e}^{\,2}\times\vec{e}^{\,3}) \tag{6.7.86}$$

where c^{te} is a constant of proportionality. Now let us play around with the prior previous relation:

$$\vec{e}^{\,1}\circ\vec{e}_1=c^{te}\vec{e}^{\,1}\circ(\vec{e}^{\,2}\times\vec{e}^{\,3})=1 \tag{6.7.87}$$

Then we get:

$$c^{te}=\frac{1}{\vec{e}^{\,1}\circ(\vec{e}^{\,2}\times\vec{e}^{\,3})}=\frac{1}{[\vec{e}^{\,1},\vec{e}^{\,2},\vec{e}^{\,3}]} \tag{6.7.88}$$

where we see appear the mixed product as we had defined it in the section of Vector Calculus.

Thus we get very easily:

$$\vec{e}_i=\frac{\vec{e}^{\,j}\times\vec{e}^{\,k}}{[\vec{e}^{\,1},\vec{e}^{\,2},\vec{e}^{\,3}]} \tag{6.7.89}$$

and even for contravariant vectors (without proof as may be too obvious?):

$$\vec{e}^{\,i}=\frac{\vec{e}_j\times\vec{e}_k}{[\vec{e}_1,\vec{e}_2,\vec{e}_3]} \tag{6.7.90}$$

Remarks

R1. The reader will have perhaps noticed that the relations above are only valid for a three-dimensional space.

R2. The notation of the two previous relations is mathematically a bit unfair because in reality it is not an equality between two vectors but an application of a vector space in the other one!

R3. As in physics is very frequently considered Cartesian , cylindrical and spherical orthonormal base and that denominator of the two previous relations is always equal to 1 in these bases than the contravariant basis vectors are identified with covariant basis vectors (and vice versa). So the covariant coordinates are equal to the contravariant coordinates for these special cases!!!!!!!!!!

Now let us come back on something that will seem very old of us... In the section of Vector Calculus, we have defined and studied what were the cross product and mixed product. We will now see another way of representing them and see that this representation provides a result for the less quite relevant!

We saw in the section of Vector Calculus that the vector product was given by:

$$\vec{x}\times\vec{y}=(x_2y_3-x_3y_2)\vec{e}_1+(x_3y_1-x_1y_3)\vec{e}_2+(x_1y_2-x_2y_1)\vec{e}_3 \tag{6.7.91}$$

But what we did not see and we will now that we can trivially this expression is only the vector determinant of the following matrices:

$$\vec{x}\times\vec{y}=\det\begin{bmatrix}\vec{e}_1 & \vec{e}_2 & \vec{e}_3\\ x_1 & x_2 & x_3\\ y_1 & y_2 & y_3\end{bmatrix}=\det\begin{bmatrix}\vec{e}_2\vec{e}_3 & \vec{e}_3\times\vec{e}_1 & \vec{e}_1\times\vec{e}_2\\ x_1 & x_2 & x_3\\ y_1 & y_2 & y_3\end{bmatrix} \tag{6.7.92}$$

Yes ... so the result does not give a scalar! It is just a usage rating.

But as we do the tensor calculus, we must now properly distinguish covariant and contravariant components. We'll rewrite it properly with contravariant components:

$$\vec{x}\times\vec{y}=\det\begin{bmatrix}\vec{e}_1 & \vec{e}_2 & \vec{e}_3\\ x^1 & x^2 & x^3\\ y^1 & y^2 & y^3\end{bmatrix} \tag{6.7.93}$$

Similarly, the mixed product can be written using this relation and notation:

$$[\vec{x},\vec{y},\vec{z}]=\vec{x}\circ(\vec{y}\circ\vec{z})=\vec{x}\circ\det\begin{bmatrix}\vec{e}_1 & \vec{e}_2 & \vec{e}_3\\ y^1 & y^2 & y^3\\ z^1 & z^2 & z^3\end{bmatrix}=(x^1\vec{e}_1+x^2\vec{e}_2+x^3\vec{e}_3)\circ\det\begin{bmatrix}\vec{e}_1 & \vec{e}_2 & \vec{e}_3\\ y^1 & y^2 & y^3\\ z^1 & z^2 & z^3\end{bmatrix} \tag{6.7.94}$$

Or, looking at the expression of the determinant we see quite easily, without having to do developments, that:

$$[\vec{x},\vec{y},\vec{z}]=\vec{e}_1\circ(\vec{e}_2\times\vec{e}_3)\det\begin{bmatrix}x^1 & x^2 & x^3\\ y^1 & y^2 & y^3\\ z^1 & z^2 & z^3\end{bmatrix} \tag{6.7.95}$$

Indeed (we calculate the determinant making use of the demonstration of the determinant with three components proved in the section of Linear Algebra):

$$\begin{aligned}
[\vec{x},\vec{y},\vec{z}]=\vec{x}\circ(\vec{y}\times\vec{z})&=\vec{e}_1\circ(\vec{e}_2\times\vec{e}_3)\det\begin{bmatrix}x^1 & x^2 & x^3\\ y^1 & y^2 & y^3\\ z^1 & z^2 & z^3\end{bmatrix}\\
&=\vec{e}_1\circ(\vec{e}_2\times\vec{e}_3)(x^1y^2z^3-x^1y^3z^2-x^2y^1z^3+x^2y^3z^1+x^2y^3z^1+x^3y^1z^2-x^3y^2z^1)\\
&=\vec{e}_1\circ\left(\begin{pmatrix}0\\1\\0\end{pmatrix}\times\begin{pmatrix}0\\0\\1\end{pmatrix}\right)(x^1y^2z^3-x^1y^3z^2-x^2y^1z^3+x^2y^3z^1+x^2y^3z^1+x^3y^1z^2-x^3y^2z^1)\\
&=\vec{e}_1\circ\begin{pmatrix}1\\0\\0\end{pmatrix}(x^1y^2z^3-x^1y^3z^2-x^2y^1z^3+x^2y^3z^1+x^2y^3z^1+x^3y^1z^2-x^3y^2z^1)\\
&=\begin{pmatrix}1\\0\\0\end{pmatrix}\circ\begin{pmatrix}1\\0\\0\end{pmatrix}(x^1y^2z^3-x^1y^3z^2-x^2y^1z^3+x^2y^3z^1+x^2y^3z^1+x^3y^1z^2-x^3y^2z^1)\\
&=(x^1y^2z^3-x^1y^3z^2-x^2y^1z^3+x^2y^3z^1+x^2y^3z^1+x^3y^1z^2-x^3y^2z^1)\\
&=((x^1y^2z^3-x^1y^3z^2)-(x^2y^1z^3-x^2y^3z^1)+(x^2y^3z^1+x^3y^1z^2-x^3y^2z^1))\\
&=(x^1(y^2z^3-y^3z^2)+x^2(y^3z^1-y^1z^3)+x^3(y^1z^2-y^2z^1))\\
&=\begin{pmatrix}x^1\\x^2\\x^3\end{pmatrix}\circ\begin{pmatrix}y^2z^3-y^3z^2\\y^3z^1-y^1z^3\\y^1z^2-y^2z^1\end{pmatrix}=\begin{pmatrix}x^1\\x^2\\x^3\end{pmatrix}\circ\left(\begin{pmatrix}y^1\\y^2\\y^3\end{pmatrix}\times\begin{pmatrix}z^1\\z^2\\z^3\end{pmatrix}\right)=\vec{x}\circ(\vec{y}\times\vec{z})
\end{aligned}\tag{6.7.96}$$

The prior-previous relation is also is frequently written:

$$[\vec{x},\vec{y},\vec{z}]=\sqrt{g}\det\begin{bmatrix}x^1 & x^2 & x^3\\ y^1 & y^2 & y^3\\ z^1 & z^2 & z^3\end{bmatrix}\tag{6.7.97}$$

with obviously:

$$\sqrt{g}=\vec{e}_1\circ(\vec{e}_2\times\vec{e}_3)=[\vec{e}_1,\vec{e}_2,\vec{e}_3]\tag{6.7.98}$$

named "Euclidean volume" (indeed let us recall that the mixed product is a volume as we show it in the section of Vector Calculus!)

Remark

Let us recall again that if the basis vectors are orthonormal, whether they are expressed in Cartesian , cylindrical or spherical coordinates then:

$$\sqrt{g}=\vec{e}_1\circ(\vec{e}_2\times\vec{e}_3)=1\tag{6.7.99}$$

Moreover, we also have the important relation:

$$\sqrt{g}=\vec{e}_1\circ(\vec{e}_2\times\vec{e}_3)=\left(\frac{\vec{e}^2\times\vec{e}^3}{[\vec{e}^1,\vec{e}^2,\vec{e}^3]}\right)\circ(\vec{e}_2\times\vec{e}_3)=\frac{(\vec{e}^2\times\vec{e}^3)(\vec{e}_2\times\vec{e}_3)}{[\vec{e}^1,\vec{e}^2,\vec{e}^3]}\tag{6.7.100}$$

Indeed, using the relation seen in the section of Vector Calculus:

$$(\vec{e}^2\times\vec{e}^3)\circ(\vec{e}_2\times\vec{e}_3)=(\vec{e}^2\circ\vec{e}_2)(\vec{e}^3\circ\vec{e}_3)-(\vec{e}^2\circ\vec{e}_3)(\vec{e}^3\circ\vec{e}_2)\tag{6.7.101}$$

But we have seen previously that $\vec{e}^i \circ \vec{e}_j = \delta^i_j$, therefore:

$$(\vec{e}^2 \circ \vec{e}_2)(\vec{e}^3 \circ \vec{e}_3) - (\vec{e}^2 \circ \vec{e}_3)(\vec{e}^3 \circ \vec{e}_2) = 1 \cdot 1 - 0 \cdot 0 \tag{6.7.102}$$

and thus finally:

$$\sqrt{g} = [\vec{e}_1, \vec{e}_2, \vec{e}_3] = \frac{1}{[\vec{e}^1, \vec{e}^2, \vec{e}^3]} \tag{6.7.103}$$

This having been done let us come back our relation of the vector product:

$$\vec{x} \times \vec{y} = x^i \vec{e}_i \times y^j \vec{e}_j = \det \begin{bmatrix} \vec{e}_1 & \vec{e}_2 & \vec{e}_3 \\ x^1 & x^2 & x^3 \\ y^1 & y^2 & y^3 \end{bmatrix} = \det \begin{bmatrix} \vec{e}_2 \times \vec{e}_3 & \vec{e}_3 \times \vec{e}_1 & \vec{e}_1 \times \vec{e}_2 \\ x^1 & x^2 & x^3 \\ y^1 & y^2 & y^3 \end{bmatrix} \tag{6.7.104}$$

and let us express the components of the 1st line of the determinant in their dual basis (in contravariant coordinates):

$$\begin{aligned} \vec{x} \times \vec{y} &= \det \begin{bmatrix} \vec{e}_1 & \vec{e}_2 & \vec{e}_3 \\ x^1 & x^2 & x^3 \\ y^1 & y^2 & y^3 \end{bmatrix} = \det \begin{bmatrix} \dfrac{\vec{e}^2 \times \vec{e}^3}{[\vec{e}^1, \vec{e}^2, \vec{e}^3]} & \dfrac{\vec{e}^3 \times \vec{e}^1}{[\vec{e}^1, \vec{e}^2, \vec{e}^3]} & \dfrac{\vec{e}^1 \times \vec{e}^2}{[\vec{e}^1, \vec{e}^2, \vec{e}^3]} \\ x^1 & x^2 & x^3 \\ y^1 & y^2 & y^3 \end{bmatrix} \\ &= \frac{1}{[\vec{e}^1, \vec{e}^2, \vec{e}^3]} \begin{bmatrix} \vec{e}^1 & \vec{e}^2 & \vec{e}^3 \\ x^1 & x^2 & x^3 \\ y^1 & y^2 & y^3 \end{bmatrix} = \sqrt{g} \begin{bmatrix} \vec{e}^1 & \vec{e}^2 & \vec{e}^3 \\ x^1 & x^2 & x^3 \\ y^1 & y^2 & y^3 \end{bmatrix} \end{aligned} \tag{6.7.105}$$

Obviously, if the cross product is expressed in covariant components then we have:

$$\begin{aligned} \vec{x} \times \vec{y} &= x_i \vec{e}^i \times y_j \vec{e}^j = \det \begin{bmatrix} \vec{e}^1 & \vec{e}^2 & \vec{e}^3 \\ x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \end{bmatrix} = \det \begin{bmatrix} \dfrac{\vec{e}_2 \times \vec{e}_3}{[\vec{e}_1, \vec{e}_2, \vec{e}_3]} & \dfrac{\vec{e}_3 \times \vec{e}_1}{[\vec{e}_1, \vec{e}_2, \vec{e}_3]} & \dfrac{\vec{e}_1 \times \vec{e}_2}{[\vec{e}_1, \vec{e}_2, \vec{e}_3]} \\ x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \end{bmatrix} \\ &= \frac{1}{[\vec{e}_1, \vec{e}_2, \vec{e}_3]} \begin{bmatrix} \vec{e}_1 & \vec{e}_2 & \vec{e}_3 \\ x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \end{bmatrix} = \frac{1}{\sqrt{g}} \begin{bmatrix} \vec{e}_1 & \vec{e}_2 & \vec{e}_3 \\ x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \end{bmatrix} \end{aligned} \tag{6.7.106}$$

Now let us apply the mixed product:

$$[\vec{x}, \vec{y}, \vec{z}] = x^i \vec{e}_i \circ (y^j \vec{e}_j \times z^k \vec{e}_k) = x^i \vec{e}_i \sqrt{g} \circ \det \begin{bmatrix} \vec{e}_1 & \vec{e}_2 & \vec{e}_3 \\ x^1 & x^2 & x^3 \\ y^1 & y^2 & y^3 \end{bmatrix} \tag{6.7.107}$$

knowing the expression of the determinant of a square 3×3 matrix (see section Linear Algebra page 1967) it comes immediately (we can detail on request as always in this textbook):

$$[\vec{x}, \vec{y}, \vec{z}] = x^i \vec{e}_i \sqrt{g} \circ \det \begin{bmatrix} \vec{e}_1 & \vec{e}_2 & \vec{e}_3 \\ x^1 & x^2 & x^3 \\ y^1 & y^2 & y^3 \end{bmatrix} = \sqrt{g} \det \begin{bmatrix} x^1 & x^2 & x^3 \\ y^1 & y^2 & y^3 \\ z^1 & z^2 & z^3 \end{bmatrix} \tag{6.7.108}$$

Conversely, it comes almost immediately:

$$[\vec{x}, \vec{y}, \vec{z}] = x_i \vec{e}^i \circ (y_j \vec{e}^j \times z_k \vec{e}^k) = \frac{1}{\sqrt{g}} \det \begin{bmatrix} x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \\ z_1 & z_2 & z_3 \end{bmatrix} \tag{6.7.109}$$

But, we have proved in the section of Vector Calculus that $x_i = \vec{x} \circ \vec{e}_i$. It comes then:

$$\begin{aligned}[\vec{x},\vec{y},\vec{z}] = x_i \vec{e}^{\,i} \circ (y_j \vec{e}^{\,j} \times z_k \vec{e}^{\,k}) &= \frac{1}{\sqrt{g}} \det \begin{bmatrix} \vec{x}\circ\vec{e}_1 & \vec{x}\circ\vec{e}_2 & \vec{x}\circ\vec{e}_3 \\ \vec{y}\circ\vec{e}_1 & \vec{y}\circ\vec{e}_2 & \vec{y}\circ\vec{e}_3 \\ \vec{z}\circ\vec{e}_1 & \vec{z}\circ\vec{e}_2 & \vec{z}\circ\vec{e}_3 \end{bmatrix} \\ &= \frac{1}{[\vec{e}_1,\vec{e}_2,\vec{e}_3]} \det \begin{bmatrix} \vec{x}\circ\vec{e}_1 & \vec{x}\circ\vec{e}_2 & \vec{x}\circ\vec{e}_3 \\ \vec{y}\circ\vec{e}_1 & \vec{y}\circ\vec{e}_2 & \vec{y}\circ\vec{e}_3 \\ \vec{z}\circ\vec{e}_1 & \vec{z}\circ\vec{e}_2 & \vec{z}\circ\vec{e}_3 \end{bmatrix}\end{aligned} \tag{6.7.110}$$

and therefore:

$$\boxed{[\vec{x},\vec{y},\vec{z}][\vec{e}_1,\vec{e}_2,\vec{e}_3] = \det \begin{bmatrix} \vec{x}\circ\vec{e}_1 & \vec{x}\circ\vec{e}_2 & \vec{x}\circ\vec{e}_3 \\ \vec{y}\circ\vec{e}_1 & \vec{y}\circ\vec{e}_2 & \vec{y}\circ\vec{e}_3 \\ \vec{z}\circ\vec{e}_1 & \vec{z}\circ\vec{e}_2 & \vec{z}\circ\vec{e}_3 \end{bmatrix}} \tag{6.7.111}$$

The latter relation is often named "Gram determinant". A special very interesting case gives us (we use the relation between the metric components and the dot products of the vector basis we proved during our study of the metric just earlier above):

$$[\vec{e}_1,\vec{e}_2,\vec{e}_3][\vec{e}_1,\vec{e}_2,\vec{e}_3] = [\vec{e}_1,\vec{e}_2,\vec{e}_3]^2 = \det \begin{bmatrix} \vec{e}_1\circ\vec{e}_1 & \vec{e}_1\circ\vec{e}_2 & \vec{e}_1\circ\vec{e}_3 \\ \vec{e}_2\circ\vec{e}_1 & \vec{e}_1\circ\vec{e}_2 & \vec{e}_2\circ\vec{e}_3 \\ \vec{e}_3\circ\vec{e}_1 & \vec{e}_3\circ\vec{e}_2 & \vec{e}_3\circ\vec{e}_3 \end{bmatrix} = \det \begin{bmatrix} g_{11} & g_{12} & g_{13} \\ g_{21} & g_{22} & g_{23} \\ g_{31} & g_{32} & g_{33} \end{bmatrix} \tag{6.7.112}$$

written in another way:

$$\boxed{(\sqrt{g})^2 = g = \det(g_{ij})} \tag{6.7.113}$$

Thus, the Euclidean volume is given by what name the "functional determinant" of the system (expression that we will see again and use in the section of General relativity to calculate the real volume and also in the section of String Theory):

$$\sqrt{g} = \sqrt{\det(g_{ij})} \tag{6.7.114}$$

that is without units (so you have to multiply it by a factor of elementary volume to get volume units). If we note in another way the determinant:

$$\sqrt{g} = \sqrt{|g|} \tag{6.7.115}$$

We get the common relation we can find in many books on General Relativity and String Theory but given without proof and named the "Riemannian volume" form or simply "volume form":

$$\boxed{V = \int\limits_V \sqrt{g} = \int\limits_V \sqrt{|g|}\mathrm{d}x^1\mathrm{d}x^2\mathrm{d}x^3} \tag{6.7.116}$$

or written in the following "invariant volume element" form:

$$\boxed{\mathrm{d}V = \sqrt{g}\mathrm{d}^4x} \tag{6.7.117}$$

The reader can verify normally easily enough that for the orthonormal Cartesian reference frame we fall back on the volume of a cube and that for the spherical case we fall back well on the expression of the infinitesimal volume of the sphere as used in the section of Geometric Shapes (but on request we can add the details here).

If we use the result we get in the section of Differential Geometry we have therefore for any surface patch:

$$V=\int\limits_V \sqrt{\det\begin{bmatrix}E & F\\ F & G\end{bmatrix}}\mathrm{d}x^1\mathrm{d}x^2\mathrm{d}x^3=\int\limits_V \sqrt{EF-F^2}\mathrm{d}x^1\mathrm{d}x^2\mathrm{d}x^3 \tag{6.7.118}$$

6.7.5 Contravariant and Covariant Components

So far we wrote the dummy indices arbitrarily on superscript or subscript at our discretion. However, this is not always allowed and sometimes the fact that a dummy index is in superscript or subscript has a special significance! This is often the major difficulty in the study of some theorems, because if we do not study those indices from the beginning, we do not really know how to interpret the position of the dummy indices. The reader should then be extremely careful at this level.

For an Euclidean vector space $\mathcal{E}^n$ reported to any base $(\vec{e}_i)$, the scalar product of a vector $\vec{x}=x^i\vec{e}_i$ by a vector $(\vec{e}_j)$ of its base is written as we know by (remember that this is equivalent as projecting the components on the axis corresponding to $\vec{e}_j$):

$$\vec{x}\circ\vec{e}_j=(x^j\vec{e}_i)\vec{e}_j=x^i g_{ij}=x_j \tag{6.7.119}$$

Therefore:

$$\boxed{x_j=x^i g_{ij}} \tag{6.7.120}$$

This relation is of major importance in theoretical physics and tensor calculus. It is important to remember it when we will study the contraction of indexes later (you can observe in the previous relation that we have "lowered" in the left side the index of the component of the right member of the equality).

These scalar products denoted x_j, are named "covariant components" in the base $(\vec{e}_i)$ of the vector $\vec{x}$. These components are therefore defined by:

$$x_j=\vec{x}\circ\vec{e}_j \tag{6.7.121}$$

They will denoted by lower indices !!! We will see later that these components are naturally introduced for some vectors of physics, for example the gradient vector. Moreover, the notion of covariant component is essential for tensors.

Remarks

R1. Never forget that this is therefore the projection of a vector on a vector of its own base!!!!

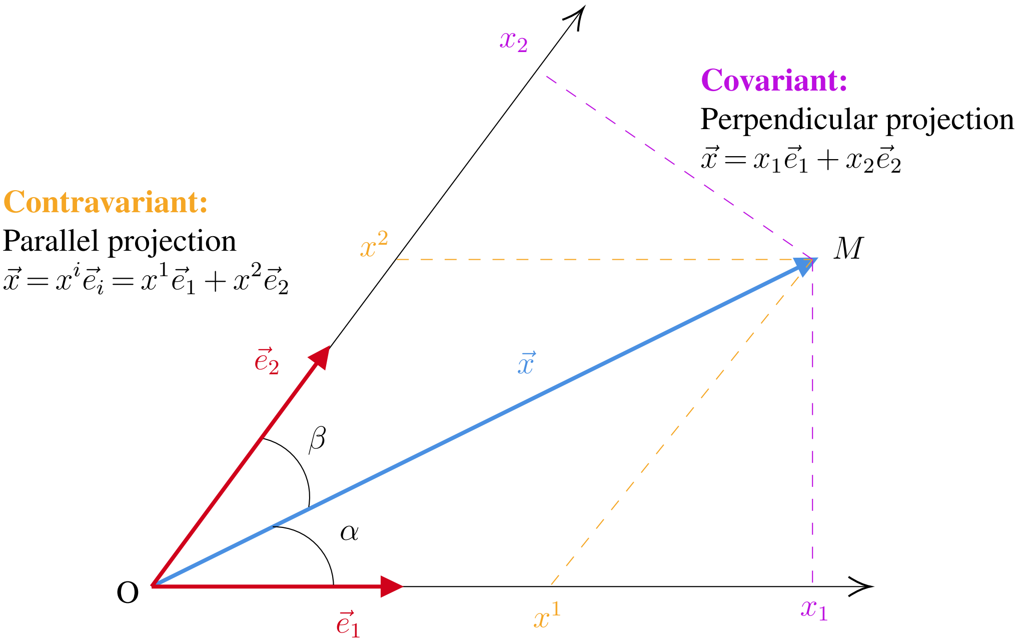
R2. The basic vectors always have their indices noted down because they are their own covariant components (they project on themselves by scalar product). This is the main trick used by beginners to remember when to put lower indices (and therefore they know when to put the upper one...)!

Conversely, the "contravariant components" (in other words: the non-projected components) can be calculated by solving with respect to the n unknowns, the system of n equations:

$$x_j = x^i g_{ij} \tag{6.7.122}$$

The previous relations show that the covariant components x_j are related to the conventional components x^i and that the contravariant components x^i are therefore numbers such that:

$$\vec{x} = x^i \vec{e}_i \tag{6.7.123}$$



x_2
Covariant:
Perpendicular projection
$\vec{x}=x_1\vec{e}_1+x_2\vec{e}_2$
Contravariant:
Parallel projection
$\vec{x}=x^i\vec{e}_i=x^1\vec{e}_1+x^2\vec{e}_2$
x^2
M
$\vec{e}_2$
$\vec{x}$
β
α
O
$\vec{e}_1$
x^1
x_1

Figure 6.155: **Covariants and Contravariants coordinates**

They will be indicated with superscripts !! The study of the basis changes later below will further justify the appellation of these different components.

In a canonical orthonormal basis (very special case and corresponding to the classical cartesian, polar, cylindric and spherical coordinates), the covariant and contravariant components are the same as we already know after our study of Gram's determinant. Indeed:

$$x_j = \vec{x} \circ \vec{e}_j = (x^i \vec{e}_i) \circ \vec{e}_j = x^i (\vec{e}_j \circ \vec{e}_j) = x^i \delta_{ij} = x^j \tag{6.7.124}$$

Remark

We see above, that the incessant writing of dummy superscript or subscript indices can sometimes lead to some confusion and serious headaches ...

Incidentally, when we refer to a vector (or, more generally, a tensor) as being either contravariant or covariant we're abusing the language slightly, because those terms really just signify two different conventions for interpreting the components of the object with respect to a given coordinate system, whereas the essential attributes of a vector or tensor are independent of the particular coordinate system in which we choose to express it. In general, any given vector or tensor (in a metrical manifold) can be expressed in both contravariant and covariant form with respect to any given coordinate system!

Furthermore It may seem that the naming convention is backwards, because the "contra" components go with the axes, whereas the "cova" components go against the axes, but historically these names were given on the basis on the transformation laws that apply to these two different interpretations.

Most of the physical definitions refer to the contravariant components. But we must be aware in physics that we if we have for example a singularity in a tensor, if may be a real physical singularity or one only due to the choice of coordinate system! There is nothing inherent in the contravariant, covariant, or mixed components for example on stress-energy tensor (in General Relativity) that cannot be changed with a coordinate transformation, EXCEPT for the scalars.

6.7.6 Operation in Basis

The interest of physicist for the tensor calculus, is passing parameters from one base to another for some given reasons (often the aim is to simplify the study of problems or simply because the studied states depend - or may depend - on the geometry of the space in question). It is therefore necessary to introduce the main tools relating thereto. We will also take this opportunity to present the developments that could have been already addressed in the section of Vector Calculus.

Remark

As I like to say... Tensor Calculus is to physics with is XML to computing science. A background independent language!

6.7.6.1 Gram-Schmidt Orthogonalization Method

The "Schmidt orthogonalization method" (also named "Gram-Schmidt orthogonalization method") allows the actual determination of an orthogonal basis for any pre-Euclidean vector space $\mathcal{E}^n$ (we could introduce this method in the section of Vector Calculus but it seemed more interesting to us to present this method in a general and aesthetic framework using tensor calculus).

For this, let us consider a set of n linearly independent vectors $(\vec{x}_1,\vec{x}_2,\ldots,\vec{x}_n)$ of $\mathcal{E}^n$ and suppose that for each vector we have the dot product (square of the norm):

$$\vec{x}_i\circ\vec{x}_i\neq 0 \tag{6.7.125}$$

Let us seek n vectors $\vec{e}_i$ orthogonal between them. Let us start for this with $\vec{e}_1=\vec{x}_1$ and let us seek for $\vec{e}_2$ orthogonal to $\vec{e}_1$ under the form (this is a choice!!!):

$$\vec{e}_2=\lambda_1\vec{e}_1+\vec{x}_2 \tag{6.7.126}$$

The mental visualization of the process is not quit easy so the reader has to trust (anyway...) the mathematical results (if once we have the time we will draw the process of the classical three dimension case).

The coefficient λ_1 is calculated by writing the orthogonality relation:

$$\vec{e}_1\circ\vec{e}_2=\vec{x}_1\circ(\lambda_1\vec{x}_1+\vec{x}_2)=0 \tag{6.7.127}$$

We deduce without too much troubles:

$$\lambda_1=-\frac{\vec{x}_1\circ\vec{x}_2}{\vec{x}_1\circ\vec{x}_1}=-\frac{\vec{x}_1\circ\vec{x}_2}{\|\vec{x}_1\|^2}=-\frac{\vec{e}_1\circ\vec{x}_2}{\|\vec{e}_1\|^2} \tag{6.7.128}$$

The parameter λ_1 being determined, we get the vector $\vec{e}_2$ that is orthogonal to $\vec{e}_1$ and not zero, since the system $(\vec{e}_1,\vec{x}_2,\ldots,\vec{x}_n)$ is linearly independent.

Thus so far we have:

$$\vec{e}_1=\vec{x}_1 \qquad \vec{e}_2=\vec{x}_2-\frac{\vec{e}_1\circ\vec{x}_2}{\|\vec{e}_1\|^2}\vec{e}_1=\vec{x}_2-\text{proj}_{e_1}\vec{x}_2 \tag{6.7.129}$$

The parameter λ_1 being determined, we get the vector $\vec{e}_2$ that is orthogonal to $\vec{e}_1$ and not zero, since the system $(\vec{e}_1,\vec{x}_2,\ldots,\vec{x}_n$ is linearly independent.

The vector $\vec{e}_2$ is sought in the form:

$$\vec{e}_3=\mu_1\vec{e}_1+\mu_2\vec{e}_2+\vec{x}_3 \tag{6.7.130}$$

The two relations of orthogonality: $\vec{e}_1\circ\vec{e}_e=0$ and $\vec{e}_2\circ\vec{e}_3=0$, enables the calculation of the coefficients μ_1 and μ_2. We get therefore:

$$\mu_1=-\frac{\vec{e}_1\circ\vec{x}_3}{\|\vec{e}_1\|^2}\qquad\mu_2=-\frac{\vec{e}_2\circ\vec{x}_3}{\|\vec{e}_2\|^2} \tag{6.7.131}$$

what determines the vector $\vec{e}_3$, orthogonal to $\vec{e}_1$ and $\vec{e}_2$, and not zero, since the $(\vec{e}_1,\vec{e}_2,\vec{x}_3,\ldots,\vec{x}_n)$ are independent. By continuing the same type of calculation, we get step by step a system of orthogonal vectors $(\vec{e}_1,\vec{e}_2,\vec{x}_3,\ldots,\vec{e}_n)$ between them and none of them are zero.

So finally:

$$\boxed{\begin{aligned}&\vec{e}_1=\vec{x}_1\\&\vec{e}_2=\vec{x}_2-\frac{\vec{e}_1\circ\vec{x}_2}{\|\vec{e}_1\|^2}\vec{e}_1=\vec{x}_2-\text{proj}_{e_1}\vec{x}_2\\&\vec{e}_3=-\frac{\vec{e}_1\circ\vec{x}_3}{\|\vec{e}_1\|^2}\vec{e}_1-\frac{\vec{e}_2\circ\vec{x}_3}{\|\vec{e}_2\|^2}\vec{e}_2+\vec{x}_3\end{aligned}} \tag{6.7.132}$$

In case where some vectors are such like $\vec{x}_i\circ\vec{x}_i=0$ (their norm is zero), we replace then $\vec{x}_i$ by $\vec{x'}_i+\lambda\vec{x}_j$, choosing a vector $\vec{x}_j$ so that we get $\vec{x'}_i\circ\vec{x'}_i\neq 0$.

We therefore conclude that any pre-Euclidean space admits orthogonal bases!

✍**Example:**

Suppose:

$$\vec{x}_1=\begin{pmatrix}1\\1\\1\end{pmatrix}\qquad\vec{x}_2=\begin{pmatrix}1\\1\\3\end{pmatrix}\qquad\vec{x}_3=\begin{pmatrix}0\\0\\3\end{pmatrix} \tag{6.7.133}$$

We want to find an orthonormal set of vector that spans $\{\vec{x}_1,\vec{x}_2,\vec{x}_3\}$. For this we use the Gram-Schmidt method followed by a normalisation, let $\vec{e}_1=\vec{x}_1=(1,1,1)$ then we calculate:

$$\vec{e}_2=\vec{x}_2-\frac{\vec{e}_1\circ\vec{x}_2}{\|\vec{e}_1\|^2}\vec{e}_1=\begin{pmatrix}1\\2\\3\end{pmatrix}-\frac{\begin{pmatrix}1\\1\\1\end{pmatrix}\circ\begin{pmatrix}1\\2\\3\end{pmatrix}}{3}\begin{pmatrix}1\\1\\1\end{pmatrix}=\begin{pmatrix}1\\2\\3\end{pmatrix}-\begin{pmatrix}2\\2\\2\end{pmatrix}=\begin{pmatrix}-1\\0\\1\end{pmatrix} \tag{6.7.134}$$

As a quick check we have indeed:

$$\vec{e}_1\circ\vec{e}_2=0 \tag{6.7.135}$$

Next:

$$\vec{e}_3 = -\frac{\vec{e}_1 \circ \vec{x}_3}{\|\vec{e}_1\|^2}\vec{e}_1 - \frac{\vec{e}_2 \circ \vec{x}_3}{\|\vec{e}_2\|^2}\vec{e}_2 + \vec{x}_3 = -\frac{\begin{pmatrix}1\\1\\1\end{pmatrix} \circ \begin{pmatrix}0\\0\\3\end{pmatrix}}{3}\begin{pmatrix}1\\1\\1\end{pmatrix} - \frac{\begin{pmatrix}-1\\0\\1\end{pmatrix} \circ \begin{pmatrix}0\\0\\3\end{pmatrix}}{2}\begin{pmatrix}-1\\0\\1\end{pmatrix} + \begin{pmatrix}0\\0\\3\end{pmatrix}$$
$$= -\frac{3}{3}\begin{pmatrix}1\\1\\1\end{pmatrix} - \frac{3}{2}\begin{pmatrix}-1\\0\\1\end{pmatrix} + \begin{pmatrix}0\\0\\3\end{pmatrix} = \begin{pmatrix}1/2\\-1\\1/2\end{pmatrix} \tag{6.7.136}$$

again it's good to check that $\vec{e}_1 \circ \vec{e}_2 = 0$ and $\vec{e}_1 \circ \vec{e}_3 = 0$ as we desire. Finally we notice that:

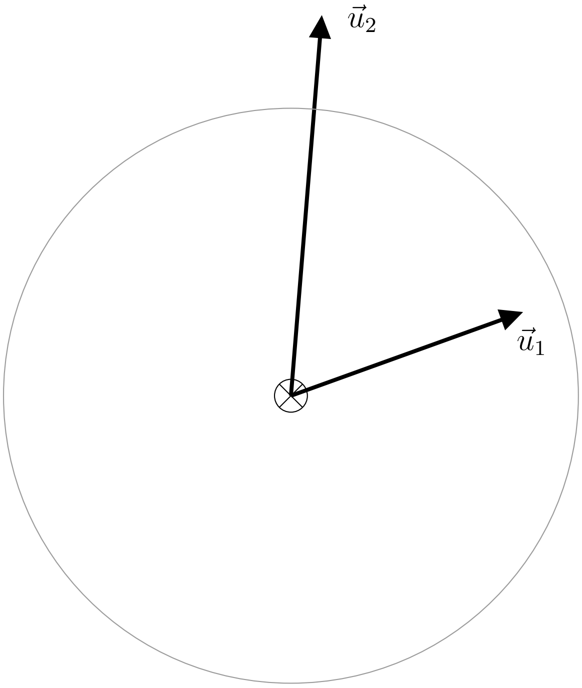
$$\|\vec{e}_1\| = \sqrt{3} \qquad \|\vec{e}_2\| = \sqrt{2} \qquad \|\vec{e}_3\| = \sqrt{3/2} \tag{6.7.137}$$

Hence:

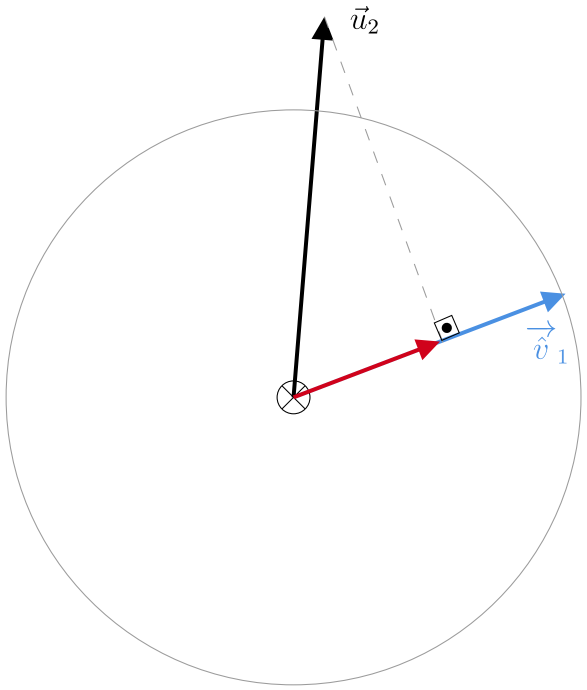
$$\vec{e}_1 = \frac{1}{\sqrt{3}}\begin{pmatrix}1\\1\\1\end{pmatrix} \qquad \vec{e}_2 = \frac{1}{\sqrt{2}}\begin{pmatrix}-1\\0\\1\end{pmatrix} \qquad \vec{e}_3 = \frac{1}{\sqrt{3/2}}\begin{pmatrix}1/2\\-1\\1/2\end{pmatrix} \tag{6.7.138}$$

are orthonormal vectors.

Perhaps pictorials will help! For simplicity, we will use only two vectors $\vec{u}_1$ and $\vec{u}_2$ against the unit circle:

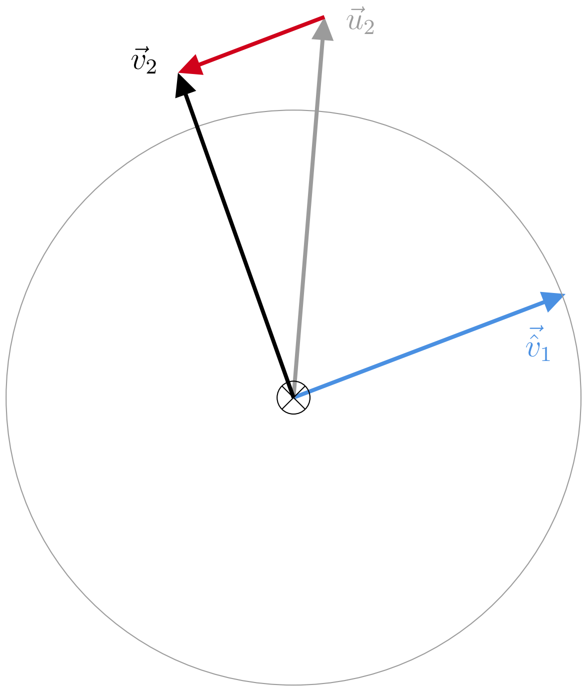


We normalize the first vector $\vec{u}_1$ and denote it $\hat{\vec{v}}_1$. Afterwards we compute the projection of the vector $\vec{u}_2$ onto the vector $\hat{\vec{v}}_1$. The projection is the red segment:



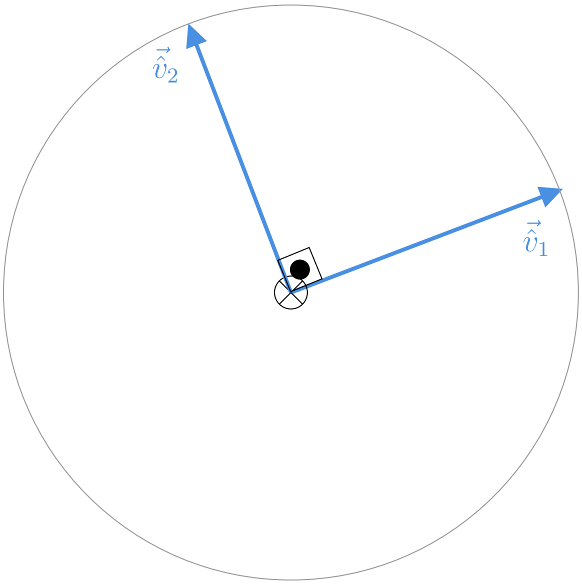
$\vec{u}_2$
$\vec{\hat{v}}_1$

We subtract afterwards the projection (red arrow) from $\vec{u}_2$. This removes the $\vec{u}_2$ components in the span of $\vec{\hat{v}}_1$. The new vector, $\vec{v}_2$, is orthogonal to $\vec{\hat{v}}_1$:



$\vec{u}_2$
$\vec{v}_2$
$\vec{\hat{v}}_1$

The last step is the normalization $\vec{\hat{v}}_2 = \vec{v}_2 / \|v_2\|$:



And for those who likes pseudocodes:

Algorithm 3: Gram-Schmidt orthogonalization

```
Input: A set of linearly independent vectors $\{\vec{x}_1, \vec{x}_2, \ldots \vec{x}_n\}$
Output: An orthonormal basis for the subspace spanned by $\{\vec{x}_1, \vec{x}_2, \ldots, \vec{x}_n\}$
for $i = 1$ to $n$ do
    $\vec{u}_i \leftarrow \vec{x}_i$
    for $j = 1$ to $i - 1$ do
        $\vec{u}_i \leftarrow \vec{u}_i - \frac{\vec{u}_i \circ \vec{u}_j}{\|\vec{u}_j\|^2}\vec{u}_j$
    $\vec{e}_i \leftarrow \frac{\vec{u}_i}{\|\vec{u}_i\|}$
```

This system of calculation of bases is of primary importance! It can be used to study physical systems from a pre-Euclidean repository whose properties change over time. Which is typical in General Relativity.

The reader interested in computer science and numerical methods can refer to the QR matrix decomposition earlier above (see page 2030) to see another application of the Gram-Schmidt orthogonalization method.

6.7.6.2 Change of Basis

Given two bases $(\vec{e}_1, \ldots, \vec{e}_n)$ and $(\vec{e}_1{}', \ldots, \vec{e}_n{}')$ of a vector space $\mathcal{E}^n$. Each vector of a base can be decomposed on the other basis as follows (we have already prove it in the section of Linear Algebra at page 1992):

$$\vec{e}_i = A'^k_i \vec{e}_k{}' \qquad \vec{e}_l{}' = A^i_k \vec{e}_i \tag{6.7.139}$$

A vector $\vec{x}$ of $\mathcal{E}^n$, when its contravariant components known, can be decomposed in each base in the form:

$$\vec{x} = x^i \vec{e}_i = x'^k \vec{e}_k{}' \tag{6.7.140}$$

and we have already proved that:

$$x^i = A^i_k x'^k \qquad x'^k = A'^k_i x^i \tag{6.7.141}$$

We notice that the transformation relations of the components of a contravariant vector are the opposite of those of the basis vectors, the quantities A and A' being permuted, hence also the origin of the name "contra"-"variants" of these components!

Let x_i and x'_k be the covariant components of a vector $\vec{x}$ respectively in the bases $(\vec{e}_i)$ and $(\vec{e}'_k)$. Let us replace the basis vectors expressed by the relations:

$$\vec{e}_i = A'^k_i \vec{e}'_k \quad \text{and} \quad \vec{e'}_k = A^k_i \vec{e}_i \tag{6.7.142}$$

in the expression of the definition of the covariant components, therefore we get:

$$x_i = \vec{x} \circ \vec{e}_i = \vec{x} \circ (A'^k_i \vec{e}'_k) = A'^k_i (\vec{x} \circ \vec{e}'_k) = A'^k_i x'_k \tag{6.7.143}$$

Hence the relation between the covariant components in each base:

$$x_i = A'^k_i x'_k \tag{6.7.144}$$

We get also:

$$x'_k = A^k_i x_i \tag{6.7.145}$$

We notice that the covariant components transform as the basis vectors, hence also the name of these components!

Once again, unless the basis is orthonormal, never forget that the covariant and contravariant components are different!!!

6.7.6.3 Reciprocal Basis (Dual Basis)

Now let us come back on the concept of dual space but as seen in the vector calculation point of view. This second approach can perhaps help some readers to better understand the concepts seen previously but against hides the underlying reasoning for the origin of the names "covariant" and "contravariant". But it is still the most common presentation used in the literature...

Given a basis $(\vec{e}_i)$ of an Euclidean vector space $\mathcal{E}^n$. By definition, n vectors $\vec{e}^k$ which satisfy the following relations:

$$\vec{e}_i \circ \vec{e}^k = \delta_{ik} \tag{6.7.146}$$

are named "reciprocal vectors" of the vectors $\vec{e}_i$. They will be denoted with higher indices. By definition, each reciprocal vector $\vec{e}^k$ must therefore be orthogonal to all the vectors $\vec{e}_i$, except for $k = i$.

Let us first show that the reciprocal vectors $\vec{e}^k$ of a given base $(\vec{e}_i)$ are linearly independent. For this, we must show that a linear combination $\lambda \vec{e}^k$ gives a zero vector if and only if each coefficient λ_k is zero.

Proof 6.45.8. Given $\vec{e}=x^i\vec{e}_i$ any vector of $\mathcal{E}_n$. Let us make a dot product by $\vec{x}$ the previous linear combination $\lambda_k\vec{e}^k$, we get:

$$(\lambda_k\vec{e}^k)\circ\vec{x}=(\lambda_k\vec{e}^k)\circ(x^i\vec{e}_i)=\lambda_k x^i(\vec{e}^k\circ\vec{e}_i)=\lambda_k x^i\delta_{ii}=\lambda_i x^i=0 \tag{6.7.147}$$

The latter equality must be verified whatever the x^i, it is therefore necessary that each λ_i is zero and thus the vectors $\vec{e}^k$ are indeed linearly independent vectors.

■ Q.E.D.

The system of n reciprocal vectors forms a basis named the "reciprocal basis" (which is just the dual basis) of the vector space $\mathcal{E}^n$.

✍**Example:**

Given three vectors $\vec{e}_1,\vec{e}_2,\vec{e}_3$ forming a basis (not necessarily orthonormal!) of an euclidean space. We decide to define first:

$$v=\vec{e}_1\circ(\vec{e}_2\times\vec{e}_3) \tag{6.7.148}$$

where, for recall, the symbol × represents the cross product (see section Vector Calculus page 1830) and the whole is the mixed product as also seen in the section Vector calculus and represents an oriented volume.

The following vectors:

$$\boxed{\vec{e}^1=\frac{\vec{e}_2\times\vec{e}_3}{v}\qquad \vec{e}^2=\frac{\vec{e}_3\times\vec{e}_1}{v}\qquad \vec{e}^3=\frac{\vec{e}_1\times\vec{e}_2}{v}} \tag{6.7.149}$$

form the dual basis!

Remark

We recognize here the relations we have just proved earlier above during our study of the Gram's determinant!!!

Now, let us consider a vector on the original base $\vec{e}_1,\vec{e}_2,\vec{e}_3$ that we will denote by (as seen above):

$$\vec{x}=x^i\vec{e}_i \tag{6.7.150}$$

with therefore by definition the contravariant components of the vector that appear as we defined earlier above (and that we had at the same time explained the origin of the name). We also saw above that each contravariant component will also (naturally and by extension) be given by:

$$x^i=\vec{x}\circ\vec{e}^i \tag{6.7.151}$$

Similarly, so we have the covariant components that appear:

$$\vec{x}=x_i\vec{e}^i \tag{6.7.152}$$

$$x_i = \vec{x} \circ \vec{e}_i \tag{6.7.153}$$

In this approach, we then define the contravariant metric tensor and respectively covariant:

$$\vec{e}_i \circ e_j = g_{ij} = g_{ji} \tag{6.7.154}$$

$$\vec{e}^{\,i} \circ e^j = g^{ij} = g^{ji} \tag{6.7.155}$$

It comes therefore for example for the contravariant components (in the case of a three-dimensional space), knowing that the approach is the same for the covariant components:

$$\begin{aligned} x^j &= \vec{x} \circ \vec{e}^{\,i} = (x_1\vec{e}^{\,1} + x_2\vec{e}^{\,2} + x_3\vec{e}^{\,3}) \circ \vec{e}^{\,i} = x_1(\vec{e}^{\,1} \circ \vec{e}^{\,i}) + x_2(\vec{e}^{\,2} \circ \vec{e}^{\,i}) + x_3(\vec{e}^{\,3} \circ \vec{e}^{\,i}) \\ &= x_1 g^{1i} + x_2 g^{2i} + x_3 g^{3i} = x_j g^{ji} \end{aligned} \tag{6.7.156}$$

And so we find the transformation relations between the contravariant and covariant components already seen above with the difference that it seems coming out of a hat by successive definitions and that therefore hides the origin of the name of these components (at least in our point of view). But perhaps some readers prefer this approach...???

✍**Example:**

As an example, consider the basis:

$$\vec{e}_1 = 2\vec{i}_1 + \vec{i}_2 \qquad \vec{e}_2 = \vec{i}_1 + 2\vec{i}_2 \qquad \vec{e}_3 = \vec{i}_3 \tag{6.7.157}$$

Notice that it is not orthogonal because $\vec{e}_1 \circ \vec{e}_2 = 4 \neq 0$.

In this case we have by applying the previous Gram's relations:

$$\begin{aligned} \vec{e}^{\,1} &= \frac{2}{3}\vec{i}_1 + \frac{1}{3}\vec{i}_2 \\ \vec{e}^{\,2} &= -\frac{1}{3}\vec{i}_1 + \frac{2}{3}\vec{i}_2 \\ \vec{e}^{\,3} &= \vec{e}_3 = \vec{i}_3 \end{aligned} \tag{6.7.158}$$

As we can see in the figure below where $\vec{e}_1$ and $\vec{e}_2$ are shown in green, and the reciprocal vectors $\vec{e}^{\,1}$ and $\vec{e}^{\,2}$ are shown in blue:

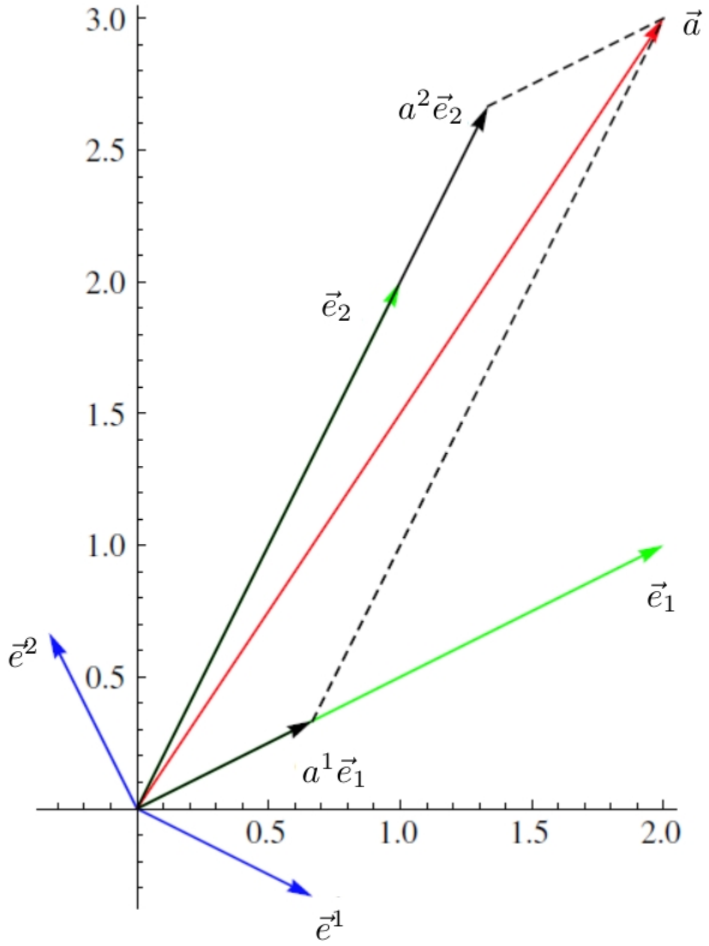


Figure 6.156: **Basis vectors, reciprocal basis vectors and contravariant components**

Notice that by construction we have indeed that $\vec{e}^1$ is orthogonal to $\vec{e}_2$ and $\vec{e}^2$ is orthogonal to $\vec{e}_1$!

For a given vector $\vec{a}$, say:

$$\vec{a} = 2\vec{\imath}_1 + 3\vec{\imath}_2 \qquad (6.7.159)$$

we can use the relation proved earlier to find its contravariant components in the basis $(\vec{e}_1, \vec{e}_2, \vec{e}_3)$. We get:

$$a^1 = \vec{a} \circ \vec{e}^1 = \frac{1}{3} \qquad a^2 = \vec{a} \circ \vec{e}^2 = \frac{4}{3} \qquad a^3 = \vec{a} \circ \vec{e}^3 = 0 \qquad (6.7.160)$$

So that (see figure above):

$$\vec{a} = \frac{1}{3}\vec{e}_1 + \frac{4}{3}\vec{e}_2 \qquad (6.7.161)$$

Now observe that the original basis vectors are reciprocal of the reciprocal ones. Thus we can just as well expand the same vector $\vec{a}$ along the basis vectors:

$$\vec{a} = a_1\vec{e}^1 + a_2\vec{e}^2 + a_3\vec{e}^3 \qquad (6.7.162)$$

with $a_i = \vec{a} \circ \vec{e}_i$.

The components a_i are the covariant components of $\vec{a}$. In our example, we get:

$$a_1 = \vec{a} \circ \vec{e}_1 = 7 \qquad a_2 = \vec{a} \circ \vec{e}_2 = 8 \qquad a_3 = \vec{a} \circ \vec{e}_3 = 0 \tag{6.7.163}$$

so we have:

$$\vec{a} = 7\vec{e}^1 + 8\vec{e}^2 \tag{6.7.164}$$

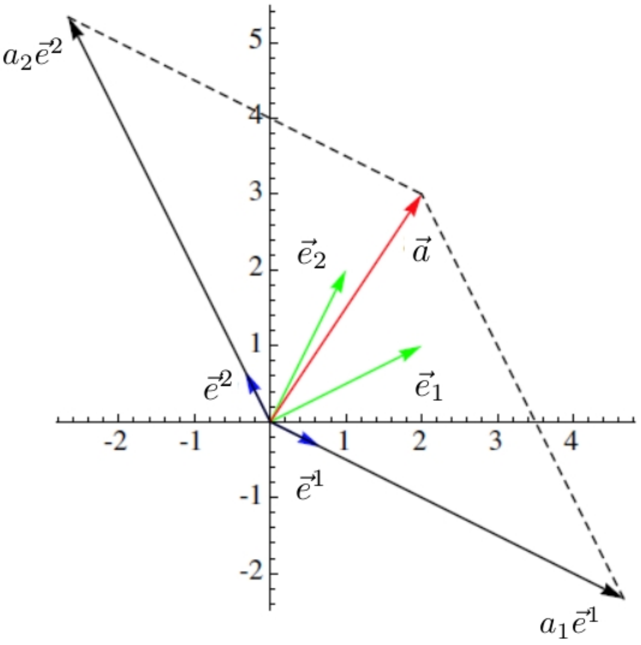

Figure 6.157: **Basis vectors, reciprocal basis vectors and covariant components**

6.7.7 Euclidean Tensors (cartesian tensor)

The generalization of the concept of vector has led us to the study of vector spaces to n dimensions. Tensors are also one-dimensional vectors but possess additional properties compared to vectors.

For the theoretical physicist, tensor calculus is interesting primarily in how the components of the tensor are transformed during a change of basis vector spaces from which they come. We will begin to study them vis-à-vis the properties of bases changes (because it is the most interesting case).

A tensor is in practice often only defined and used in the form of its components. These can be expressed in covariant or contravariant form like any vector. But a new type of components will appear in the tensor, it is the "mixed components". These three types of components are decomposition of Euclidean tensor on different bases.

Definition (#6.7.264): A "Cartesian tensor" uses an orthonormal basis to represent a tensor in a Euclidean space in the form of components.

Use of Cartesian tensors occurs in physics and engineering, such as with the Cauchy stress tensor (see section Continuum Mechanics page 3815) and the moment of inertia tensor in rigid body dynamics (see section Classical Mechanics page 3310). Sometimes general curvilinear coordinates are convenient, as in high-deformation continuum mechanics, or even necessary, as in General Relativity (see section General Relativity page 5720).

6.7.7.1 Fundamental Tensor

During the theory view earlier above, we used the quantities g_{ij}, defined from the scalar product of the basis vectors $(\vec{e}_i)$ of a n-dimensional pre-Euclidean vector space $\mathcal{E}^n$, by:

$$g_{ij} = \vec{e}_i \circ \vec{e}_j \tag{6.7.165}$$

These n^2 quantities are the covariant components of a tensor named the "fundamental tensor" or as we already know the "metric tensor".

Let us study now how vary the quantities g_{ij} when we make a basis change!

Given $(\vec{e}'_k)$ another base linked to the previous by the known relation:

$$\vec{e}_i = A'^k_i \vec{e}'_k \quad \text{and} \quad \vec{e}'_k = A^i_k \vec{e}_i \tag{6.7.166}$$

Substituting the relation $\vec{e}_i = A'^k_i \vec{e}'_k$ in the expression of g_{ij}, it come (we change the indices as it should be done during a substitution):

$$g_{ij} = (A'^k_i \vec{e}'_k) \circ (A'^l_j \vec{e}'_l) = (A'^k_i A'^l_j)(\vec{e}'_k \circ \vec{e}'_l) \tag{6.7.167}$$

In the new base $(\vec{e'}_k)$, the dot products of the basis vectors are therefore quantities such that:

$$g'_{kl} = \vec{e}'_k \circ \vec{e}'_l \tag{6.7.168}$$

So we finally have for the expression of the covariant components g_{ij} in a basis change:

$$\boxed{g_{ij} = (A'^k_i A'^l_j) g'_{kl}} \tag{6.7.169}$$

Identically we have:

$$\boxed{g'_{ij} = (A^k_i A^l_j) g_{kl}} \tag{6.7.170}$$

In general, a sequence of n^2 quantities t_{ij} that transforms, during a base change of $\mathcal{E}^n$, according to the two previous relations, namely:

$$t_{ij} = (A'^k_i A'^l_j) g'_{kl} \qquad \text{and} \qquad t'_{ij} = (A^k_i A^l_j) t_{kl} \tag{6.7.171}$$

are, by definition, the "covariant components of a tensor of order two" (with two indices) on $\mathcal{E}^n$.

We can therefore manipulate quantities expressing the intrinsic properties of bases as standard tensors!

6.7.7.2 Tensor product (dyadic) of two vectors and matrices

Let us consider an Euclidean vector space $\mathcal{E}^n$ of base $(\vec{e}_i)$ and given two vector of $\mathcal{E}^n$:

$$\vec{x}=x^i\vec{e}_i \quad \text{and} \quad \vec{y}=y^j\vec{e}_j \tag{6.7.172}$$

Let us form the two by two products of contravariant components x^i and y^j, namely:

$$u^{ij}=x^iy^j \tag{6.7.173}$$

We thus get n^2 quantities, if the two vectors have the same number of components, which are also the contravariant components of a tensor of order two named the "tensor product" of the vector $\vec{x}$ by the vector $\vec{y}$.

For example for $\vec{x}$ of dimension 2 and $\vec{y}$ of dimension 3 we have:

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \otimes \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} x_1y_1 \\ x_1y_2 \\ x_1y_3 \\ x_2y_1 \\ x_2y_2 \\ x_2y_3 \end{pmatrix} \tag{6.7.174}$$

Remark

In quantum physics a "Fock space" defined as the tensor product of all n-body Hilbert spaces. Suppose we have a system described by a Hilbert space H, for example a single particle. The Hilbert space of two non-interacting particles of the same type as that described by H is simply the tensor product:

$$H^2:=H\otimes H \tag{6.7.175}$$

More generally, for a system of N particles as above, the Hilbert space is:

$$H^N:=\underbrace{H\otimes\cdots\otimes H}_{N\text{ times}} \tag{6.7.176}$$

We can also tensorally multiply two matrices A and B. Then, the matrix describing the tensor product $A\otimes B$ is the "Kronecker product" of the two matrices as we use it in Relativistic Quantum Physics.

For example, if:

$$A=\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \qquad B=\begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \tag{6.7.177}$$

Then:

$$A\otimes B=\begin{bmatrix}a_{11}&a_{12}\\a_{21}&a_{22}\end{bmatrix}\otimes\begin{bmatrix}b_{11}&b_{12}\\b_{21}&b_{22}\end{bmatrix}=\begin{bmatrix}a_{11}\begin{bmatrix}b_{11}&b_{12}\\b_{21}&b_{22}\end{bmatrix}&a_{12}\begin{bmatrix}b_{11}&b_{12}\\b_{21}&b_{22}\end{bmatrix}\\a_{21}\begin{bmatrix}b_{11}&b_{12}\\b_{21}&b_{22}\end{bmatrix}&a_{22}\begin{bmatrix}b_{11}&b_{12}\\b_{21}&b_{22}\end{bmatrix}\end{bmatrix}$$
$$=\begin{bmatrix}a_{11}b_{11}&a_{11}b_{12}&a_{12}b_{11}&a_{12}b_{12}\\a_{11}b_{21}&a_{11}b_{22}&a_{12}b_{21}&a_{12}b_{22}\\a_{21}b_{11}&a_{21}b_{12}&a_{22}b_{11}&a_{22}b_{12}\\a_{21}b_{21}&a_{21}b_{22}&a_{22}b_{21}&a_{22}b_{22}\end{bmatrix}\qquad(6.7.178)$$

The most famous case is the covariant tensor of rank 2 in a space of 4 dimensions as it is the most used one in tensor calculus:

$$T_{ij}=\vec{x}\otimes\vec{y}=\begin{pmatrix}x_1\\x_2\\x_3\\x_4\end{pmatrix}\otimes\begin{pmatrix}y_1\\y_2\\y_3\\x_4\end{pmatrix}=\begin{pmatrix}x_1y_1&x_1y_2&x_1y_3&x_1y_4\\x_2y_1&x_2y_2&x_2y_3&x_2y_4\\x_3y_1&x_3y_2&x_3y_3&x_3y_4\\x_4y_1&x_4y_2&x_4y_3&x_4y_4\end{pmatrix}\qquad(6.7.179)$$

The reader can also now better understand the origin of the name of the gradient of a vector field (giving a "tensor field") as we saw in the section of Vector Calculus because we can rewrite it now:

$$\vec{\nabla}(\vec{f})=\frac{\partial f_i}{\partial x_j}=\begin{bmatrix}\dfrac{\partial f_1}{\partial x}&\dfrac{\partial f_1}{\partial y}&\dfrac{\partial f_1}{\partial z}\\\dfrac{\partial f_2}{\partial x}&\dfrac{\partial f_2}{\partial y}&\dfrac{\partial f_2}{\partial z}\\\dfrac{\partial f_3}{\partial x}&\dfrac{\partial f_3}{\partial y}&\dfrac{\partial f_3}{\partial z}\end{bmatrix}=\vec{\nabla}\otimes\vec{f}\qquad(6.7.180)$$

The reader will have certainly notice that through the examples above, the tensor product is non-commutative. That is:

$$\vec{x}\otimes\vec{y}\neq\vec{y}\otimes\vec{x}\qquad(6.7.181)$$

We can obviously build tensor products of order three (thus with n^3 terms) such as with the following tensor three times contravariant vectors:

$$u^{ijk}=x^iy^jz^k\qquad(6.7.182)$$

etc.

Let us study the properties of the basis changes of these components. Let us use for the basis changes relations of contravariant components of a vector, namely:

$$x^i=A_k^ix'^k\quad\text{and}\quad x'^k=A'^k_ix^i\qquad(6.7.183)$$

Let us replace in the relation $u^{ij}=x^iy^j$ the components x^i and y^i by their basis change expression, we get:

$$u^{ij}=x^iy^j=(A_k^ix'^k)(A_l^jy'^l)=A_k^iA_l^j(x'^ky'^l)=(A_k^iA_l^j)u'^{kl}\qquad(6.7.184)$$

The quantities u'^{kl} are the new components:

$$u'^{kl}=x'^{k}y'^{l} \tag{6.7.185}$$

The transformation formula of the n^2 quantities u^{ij} on a change of basis change of $\mathcal{E}^n$ is finally (very similar to metric tensor):

$$\boxed{u^{ij}=A_k^iA_l^ju'^{kl}} \tag{6.7.186}$$

Such a change basis relation characterizes the contravariant components of a tensor of order two. Conversely, we get:

$$\boxed{u'^{ij}=A'^{k}_{k}A'^{l}_{j}u^{ij}} \tag{6.7.187}$$

So the n^2 quantities are the "contravariant components of a tensor of order two".

We can then build the same products by pairs for covariant components x_i and y_i of the vectors $\vec{x}$ and $\vec{y}$ thus:

$$u_{ij}=x_iy_i \tag{6.7.188}$$

The formulas of basis change of the covariant components of the vectors are given by the following relations that we have already proved previously:

$$x_i=A'^{k}_{i}x'_{k}\quad \text{and}\quad x'_{k}=A_k^ix_i \tag{6.7.189}$$

Substituting the first relation in the product $u_{ij}=x_iy_i$, we get:

$$u_{ij}=(A'^{k}_{i}x'_{k})(A'^{l}_{j},y'_{l})=A'^{k}_{i}A'^{l}_{j}(x'_{k}y'_{l})=(A'^{k}_{i}A'^{l}_{j})u'_{kl} \tag{6.7.190}$$

This is the basis change relation of covariant components of a tensor of order two. We also easily check that we have:

$$u'_{kl}=A_k^iA_l^ju_{ij} \tag{6.7.191}$$

Identically we have of course $u'_{kl}=x'_{k}y'_{l}$ since $u_{ij}=x_iy_i$.

So the n^2 quantities are then the "covariant components of a tensor of order two".

Let us now create n^2 quantities my multiplying two by two the covariant components of a vector $\vec{x}$ by contravariant components of a vector $\vec{y}$, we get:

$$u_i^j=x_iy^j \tag{6.7.192}$$

Let us perform a basis change in this last relation taking into account the expressions $x_i=A'^{k}_{i}x'_{k}$ and $x^i=A_k^ix'^{k}$, we get:

$$u_i^j=x_iy^j(A'^{k}_{i}x'_{k})(A_l^jy'^{l})=A'^{k}_{i}A_l^j(x'_{k}y'^{l})=(A'^{k}_{i}A_l^j)u'^{l}_{k} \tag{6.7.193}$$

This basis change relation characterizes the "mixed components" of an order two tensor. Conversely, we can verify that we have:

$$u'^{l}_{k}=A_k^iA'^{l}_{j}u_i^j \tag{6.7.194}$$

These mixed components also constitutes the components of a tensor product of $\vec{x}$ by $\vec{y}$, according to a given basis.

In general, a sequence of n^2 quantities that transforms, during a basis of $\mathcal{E}^n$, just as previously established relation are therefore, by definition, "mixed components of a tensor of order two".

6.7.7.3 Tensor Spaces

In the previous study, we used as system of n^2 number, created from a vector space $\mathcal{E}^n$. When these numbers satisfy some basis change relations, we name these quantities, by definition, "components of a tensor".

We have seen that any linear combination of these components constitutes the components of a new tensor. We can therefore add together the components of the tensor and multiply by a scalar, to get other components of a new tensor. These addition and multiplication properties mean that we can use these tensors quantities as vector components.

To clarify how we define a tensor on a base, let us study the particular case of a tensor product of two vectors formed by triplets of numbers (that is to say in $\mathbb{R}^3$ typically). Consider therefore the Euclidean vector space $\mathcal{E}^3$ whose vectors are triplets of number of the form $\vec{x}=(x_1,x_2,x_3)$. The canonical orthonormal basis of $\mathcal{E}^3$ consists of three vectors that we know very well but written in tensor calculus as:

$$\vec{e}_i=(\delta_{1i},\delta_{2i},\delta_{3i}) \tag{6.7.195}$$

with $i=1,2,3$ (nice way to write simple things isn't it...).

Vectors of $\mathcal{E}^3$ gives the possibility to form the nine quantities that we have named the "components of the tensor product" of the vectors $\vec{x}$ and $\vec{y}$.

If we make all possible tensor products between vectors of $\mathcal{E}^3$, we get sequences of 9 numbers that can be used to define the following vector:

$$\vec{x}\otimes\vec{y}=\vec{U}=\left(x^1y^1,x^1y^2,x^1y^3,\ldots,x^3y^3\right) \tag{6.7.196}$$

Remark

We see immediately with the above relation and the previous relation that the tensor product is therefore not commutative.

We are left then with the elements of a vector space $\mathcal{E}^9$ with nine-dimensional space, whose elements all combinations by pairs of three numbers.

We then say that $\mathcal{E}^9$ has a "tensor product structure" which is denoted obviously and in standard calculus by $\mathcal{E}^9:\mathcal{E}^3\otimes\mathcal{E}^3$ or sometimes $\mathcal{E}_3^{(2)}$.

These vectors can be decomposed, for example, on an orthonormal canonical basis:

$$\vec{e}_k=(\delta_{1k},\delta_{2k},\ldots,\delta_{9k}) \tag{6.7.197}$$

with $k=1,2,\ldots,9$.

If we rewrite the quantities x^iy^j according to their place in the expression of $\vec{U}$, i.e.:

$$x^iy^j=u^{ij}=u^k \tag{6.7.198}$$

with $k=1,2,\ldots,9$ and $i,j=1,2,3$, the vectors $\vec{U}$ are then written:

$$\vec{U}=u^k\vec{e}_k \tag{6.7.199}$$

and is an example as we know of tensor of order 2 (obviously we can generalize this approach).

How do these tensor differ from ordinary vectors? Although they are identical to some vectors of $\mathcal{E}^9$ in our example but were formed by the vectors $\vec{x}$ and $\vec{y}$ of $\mathcal{E}^3$. To remember this fact, we write then as we already know:

$$\boxed{T_{ij}=\vec{U}=\vec{x}\otimes\vec{y}} \tag{6.7.200}$$

and they are named as we already know "tensor products of order two" of the vectors $\vec{x}$ and $\vec{y}$. The symbol $\otimes$ is defined in the way we have formed the quantities $x^iy^j=u^{ij}$ and in the order in which they were classified them to form the vector $\vec{U}$.

To recall the dependence between a quantity $x^iy^j=u^{ij}$ and the basis vector $\vec{e}_i$ to which he is assigned, let us rewrite these vectors by putting in place of the index k the two indices i and j, relative to the components, namely:

$$\vec{e}_k=\vec{e}_{ij} \tag{6.7.201}$$

The latter can be written in the form:

$$\boxed{\vec{e}_k=\vec{e}_{ij}=\vec{e}_i\otimes\vec{j}} \tag{6.7.202}$$

The vectors $\vec{e}_i\otimes\vec{j}$ generates a basis of $\mathcal{E}^9$ in the case of our example that is named the "tensor associated basis".

✍**Example:**

Consider:

$$\vec{e}_1=\begin{pmatrix}1\\0\\0\end{pmatrix},\ \vec{e}_2=\begin{pmatrix}0\\1\\0\end{pmatrix},\ \vec{e}_3=\begin{pmatrix}0\\0\\1\end{pmatrix} \tag{6.7.203}$$

We then have for example:

$$\vec{e}_{12}=\vec{e}_1\otimes\vec{e}_2=\begin{bmatrix}1\cdot 0 & 1\cdot 1 & 0\cdot 0\\ 0\cdot 0 & 0\cdot 1 & 0\cdot 0\\ 0\cdot 0 & 0\cdot 0 & 0\cdot 0\end{bmatrix}=\begin{bmatrix}0 & 1 & 0\\ 0 & 0 & 0\\ 0 & 0 & 0\end{bmatrix} \tag{6.7.204}$$

That is to say:

$$\vec{e}_1:=\vec{e}_{12}=\begin{pmatrix}0\\1\\0\\0\\0\\0\\0\\0\\0\end{pmatrix} \tag{6.7.205}$$

It follows that as element of a space $\mathcal{E}^n \otimes \mathcal{E}^n$, a tensor $\vec{U}$ is a vector of the general form:

$$\boxed{\vec{U} = u^{ij}(\vec{e}_i \otimes \vec{e}_j)} \tag{6.7.206}$$

Let us study its properties vis-à-vis a base change of $\mathcal{E}^n$ such that:

$$\vec{e}_i = {A'}^k_i \vec{e}\,'_k = A^i_k \vec{e}_i \tag{6.7.207}$$

During such a base change, the base $(\vec{e}_i \otimes \vec{e}_j)$ associated to $\vec{e}_i$ becomes another base $(\vec{e}\,'_k \otimes \vec{e}\,'_l)$ associated to $\vec{e}\,'_k$, that is:

$$\vec{e}\,'_k \otimes \vec{e}\,'_l = (A^i_k \vec{e}_i) \otimes (A^j_l \vec{e}_j) = (A^i_k A^j_l) \otimes \vec{e}_j \tag{6.7.208}$$

It follows that the tensor product $\vec{U}$ has for components in the new basis:

$$\vec{U} = {u'}^{kl}(\vec{e}\,'_k \otimes \vec{e}\,'_l = {u'}^{kl}(A^i_k A^j_l)\vec{e}_i \otimes \vec{e}_j = ({A'}^k_i {A'}^l_j)u^{ij}(A^i_k A^j_l)\vec{e}_i \otimes \vec{e}_j \tag{6.7.209}$$

We have the following properties for the tensor product given:

$$\vec{x} \otimes \vec{y} = (x^i \vec{e}_i) \otimes (y^j \vec{e}_j) = x^i y^j (\vec{e}_i \otimes \vec{e}_j) \tag{6.7.210}$$

P1. Right/Left distributivity relatively to the addition of vectors:

$$\begin{aligned}(\vec{x}+\vec{y}) \otimes \vec{z} &= \vec{x} \otimes \vec{z} + \vec{y} \otimes \vec{z}\\ \vec{x} \otimes (\vec{y}+\vec{z}) &= \vec{x} \otimes \vec{y} + \vec{x} \otimes \vec{z}\end{aligned} \tag{6.7.211}$$

The proof of these relations is simply deduced from the definition of the tensor product. Indeed, we have for example:

$$\begin{aligned}(\vec{x}+\vec{y}) \otimes \vec{z} &= (x^i\vec{e}_i + y^i\vec{e}_i) \otimes z^k\vec{e}_k = (x^i + y^i)\vec{e}_i \otimes z^k\vec{e}_k = (x^i + y^i)z^k\vec{e}_i \otimes \vec{e}_k\\ &= x^i z^k \vec{e}_i \otimes \vec{e}_k + y^i z^k \vec{e}_i \otimes \vec{e}_k = \vec{x} \otimes \vec{z} + \vec{y} \otimes \vec{z}\end{aligned} \tag{6.7.212}$$

P2. Associativity with multiplication by a scalar:

$$(\lambda\vec{x}) \otimes \vec{y} = \vec{x} \otimes (\lambda\vec{y}) = \lambda(\vec{x} \otimes \vec{y}) \tag{6.7.213}$$

Indeed, we have:

$$(\lambda\vec{x}) \otimes \vec{y} = (\lambda x^i \vec{e}_i)\vec{x} \otimes y^i\vec{e}_i = \lambda x^i y^j (\vec{e}_i \otimes \vec{e}_j) = \lambda(\vec{x} \otimes \vec{y}) \tag{6.7.214}$$

P3. When we choose a base in each of the vector spaces $(\vec{e}_i)$ for $\mathcal{E}^n$, $(\vec{f}_i)$ for $\mathcal{F}^m$, the $n \cdot m$ elements of G_{nm} that we denote by $\vec{e}_i \otimes \vec{f}_i$ also form a basis of G_{nm}.

Proof 6.45.9. Already made in the particular example we used earlier above.

■ Q.E.D.

Remark

In practice, we often have to use tensor formed from vectors belonging to the same vector spaces $\mathcal{E}^n$.

We can of course generalize the tensor product to any number of vectors. Gradually, given the property P1, we can consider p vectors $\vec{x}_1, \vec{x}_2, \ldots, \vec{x}_p$ each belonging to different vector spaces $\mathcal{E}^{n_1}, \mathcal{E}^{n_2}, \ldots, \mathcal{E}^{n_p}$. If we have:

$$\vec{x}_1 = x^{i1}\vec{e}_{i1}, \vec{x}_2 = x^{i2}\vec{e}_{i2}, \ldots \tag{6.7.215}$$

we can form the tensor product:

$$\vec{x}_1 \otimes \vec{x}_2 \otimes \ldots \otimes \vec{x}_p = x^{i1}x^{i2}\ldots x^{ip}(\vec{e}_{i1} \otimes \vec{e}_{i2} \otimes \ldots \otimes \vec{e}_{ip}) \tag{6.7.216}$$

with $i_1 = \{1, \ldots, n_1\}, i_2 = \{1, \ldots, n_2\}, \ldots, i_p = \{1, \ldots, n_p\}$.

We build thus tensor products of order p belonging to the vector space $\mathcal{E}^{n_1} \otimes \mathcal{E}^{n_2} \otimes \ldots \otimes \mathcal{E}^{n_p}$, space that has a product structure tensor. The elements of this space are by definition tensor of order p.

In order to unify the classification, the elementary vector spaces, which can not be fitted with a tensor product structure can be regarded as having components of a tensor of order 1. In general, we name these elements "vectors", reserving the term "tensor" to elements of tensor spaces of order equal or greater than 2!

Remark

It is of usage to name "tensor of order zero" scalar quantities. It is also rare to meet tensor of order tensor greater than 2.

It is quite obvious and we will not do the proof that we absolutely can redefine all the concepts (base, decomposition on a base, reciprocal basis, dot product, tensor product) that we have seen so far considering tensor of order 1 as a vector (we should therefore rewrite everything that was already written above... which is useless in our point of view).

It is also quite possible to repeat all these definitions for higher order tensor and thus generalize the concept of space tensor for all dimensions.

From these considerations, we can state the "tensoriality criterion":

So that the elements of a sequence of n^p, relative to a base of a vector space $\mathcal{E}^n_{(p)}$, can be considered as the components of a tensor, it is necessary and sufficient that these quantities to be linked together, in two different bases of $\mathcal{E}^n_{(p)}$, by the relations of transformation of the components.

Remark

A vector can be represented in any base by a sequence of n components. However, we can not conclude that any sequence of n numbers is a vector. Indeed, when we put ourselves in another base of space, the components must also change to represent the same object, then we say that the vector is an intrinsic object (whose existence does not depend on the choice of the base). It remains then to know that a vector is a tensor of order 1.

6.7.7.4 Linear combination of tensors

We can form other tensor by combining together the components of various tensor products defined using vectors of the same vector space. For example, let us consider the contravariant components of the tensor products of the vectors $\vec{x},\vec{y}$ and $\vec{w},\vec{z}$:

$$u^{ij}=x^iy^j \qquad v^{ij}=w^iz^j \tag{6.7.217}$$

Let us form the following quantities:

$$t^{ij}=u^{ij}+\lambda v^{ij} \tag{6.7.218}$$

The n^2 quantities t^{ij} also satisfied the general formulas for basis change. We have indeed by substituting the relations of transformation of the contravariant components of a tensor product in the previous expression:

$$t^{ij}=A_k^iA_l^ju'^{kl}+\lambda A_k^iA_l^jv'^{kl}=A_k^iA_l^jt'^{kl} \tag{6.7.219}$$

The n^2 quantities t^{ij}, satisfying the relations of basis change also constitutes components of a tensor of order two.

6.7.7.5 Contraction of indices

Let us consider the mixed tensor product of two vectors $\vec{x}$ and $\vec{y}$ of respective contravariant x^i and covariant y_j components. The mixed components of the tensor product $\vec{V}$ of these two vectors are:

$$v_j^i=x^iy_j \tag{6.7.220}$$

Let us perform the addition of the various components of the tensor $\vec{V}$ such as $i=j$, i.e.:

$$v=x^iy_i \tag{6.7.221}$$

We thus get the expression of the dot product of vectors $\vec{x}$ and $\vec{y}$. The quantity v is a scalar (tensor of order zero). Such an addition on different variance indices constitutes, by definition, the operation of "contraction of indices" of the tensor $\vec{V}$. This operation allowed us to move from a tensor of order two to a tensor of order zero. The tensor $\vec{V}$ has been amputated and of a covariance and a contravariance.

Let us also take the example of a tensor $\vec{U}$ whose mixed components are one time covariant and one two times contravariant u_k^{ij} (caution ... it is not a three-dimensional matrix but simply an indication that the components of this tensor are expressed from three other variables!!!). Let us consider some of its components such as $k=j$, that is the components u_j^{ij} and let us perform the addition of the latter. We then get:

$$v^i=u_1^{i1}+u_2^{i2}+\ldots+u_n^{in}=\delta_j^ku_k^{ij} \tag{6.7.222}$$

These new quantities v^i form the components of a tensor $\vec{V}$ of order one (thus a vector!) and constitute what we name then the "contracted components" of the tensor $\vec{U}$ and of course meet the basis relations change (on request we can prove it but you have to know that it is similar to the one we made for vectors). So we have indeed change form a tensor of order three to a tensor of order one!

So we can see that the underlying idea of the contraction is to allow us to facilitate the resolution of a purely mathematical problem and depending on the situation it may be good to raise or reduce the order of a tensor. This is often a choice that is made by trial and error based on a specific context or that naturally arises from a purely mathematical or mathematical-physical development (as we will see examples further below).

6.7.7.5.1 Raising and lowering indices

If we start with a contravariant or covariant components tensor , we can lower / raise one or more indices by multiplication (if repeated) by g_{ij} or g^{ij} (unitary diagonal and positive signature: of canonical type) to get mixed components on which we can then perform contraction operations.

Let us consider an Euclidean tensor $\vec{U}$ of contravariant components $u^{i_1 i_2 i_3 \ldots i_p}$.

If we want to perform a contraction on this tensor, we will first need to transform it into a mixed tensor. This transformation we be done using a fundamental tensor.

Let us write $\vec{U}$ in mixed components by lowering at the covariant position the index i_1 by example (it is therefore equivalent to express this in contravariant component in covariant component). So:

$$u_{j_1}^{i_2 i_3 \ldots i_p} = g_{i_1, j_1} u^{i_1 i_2 i_3 \ldots i_p} \tag{6.7.223}$$

We see well that in this case to take down a contravariant index in a tensor using a fundamental tensor, we must first go search in the covariants components of the fundamental tensor the one who is itself in contravariant position in the original tensor and replace its position (but this time in covariance) by the other index of the fundamental tensor (it is the same idea when it we desire to operate a contraction on a covariant tensor).

Indeed, let us recall that we have proved that:

$$x_j = g_{ij} x^i \tag{6.7.224}$$

Also remember that raising and then lowering the same index (or conversely) are inverse operations, which is reflected in the covariant and contravariant metric tensors being inverse to each other:

$$g^{ij} g_{jk} = g_{kj} g^{ji} = \delta_k^i \tag{6.7.225}$$

Now that we got a mixed tensor components, we can very well getting contract the indices. Let us choose for example the index i_2 and let us perform the contraction with the index j_1, let us put $i_2 = j_1 = k$ (we are then concerned only to some specific terms), then just writing the whole process from the beginning:

$$g_{i_1 j_1} u^{i_1 i_2 i_3 \ldots i_p} = u_{j_1}^{i_2 i_3 \ldots i_p} = u_k^{k i_3 \ldots i_p} = v^{i_3 \ldots i_p} \tag{6.7.226}$$

So we get after lowering the index and one contraction, a tensor of order $p-2$.

✍**Examples:**

E1. Let us see a first example of raising down and contracting the covariant 4-position first order tensor given by (see section Special Relativity page 5639):

$$X_\mu = (-ct, x, y, z) \tag{6.7.227}$$

in components:

$$X_0 = -ct \qquad X_j = x_j \tag{6.7.228}$$

(where x_j are the usual Cartesian coordinates) and the Minkowski metric tensor with signature $(-+++)$ given by (see section Special Relativity page 5705):

$$\eta_{\mu\nu} = \eta^{\mu\nu} = \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \tag{6.7.229}$$

in components:

$$\eta_{00} = -1 \qquad \eta_{i0} = \eta_{0i} = 0 \qquad \eta_{ij} = \delta_{ij} \tag{6.7.230}$$

To raise the index, multiply by the tensor and contract:

$$X^\lambda = \eta^{\lambda\mu} X_\mu = \eta^{\lambda 0} X_0 + \eta^{\lambda i} X_i \tag{6.7.231}$$

Then for $\lambda = 0$:

$$X^0 = \eta^{00} X_0 + \eta^{0i} X_i = -X_0 \tag{6.7.232}$$

and for $\lambda = j = 1, 2, 3$:

$$X^j = \eta^{j0} X_0 + \eta^{ji} X_i = \delta^{ji} X_i = X_j \tag{6.7.233}$$

So the index-raised contravariant 4-position is:

$$X^\mu = (ct, x, y, z) \tag{6.7.234}$$

E2. For a second order tensor example let us consider the contravariant electromagnetic tensor in the $(+---)$ signature is given by (see section Electrodynamics page 4121):

$$F^{\alpha\beta} = \begin{pmatrix} 0 & -E_x/c & -E_y/c & -E_z/c \\ E_x/c & 0 & -B_z & B_y \\ E_y/c & B_z & 0 & -B_x \\ E_z/c & -B_y & B_x & 0 \end{pmatrix} \tag{6.7.235}$$

in components:

$$F^{0i} = -F^{i0} = -E^i/c \qquad F^{ij} = -\varepsilon^{ijk} B_k \tag{6.7.236}$$

To get the covariant tensor $F_{\alpha\beta}$, we multiply by the metric tensor and contract:

$$\begin{aligned}F_{\alpha\beta}&=\eta_{\alpha\gamma}\eta_{\beta\delta}F^{\gamma\delta}\\&=\eta_{\alpha0}\eta_{\beta0}F^{00}+\eta_{\alpha i}\eta_{\beta0}F^{i0}+\eta_{\alpha0}\eta_{\beta i}F^{0i}+\eta_{\alpha i}\eta_{\beta j}F^{ij}\end{aligned}\qquad(6.7.237)$$

and since $F^{00}=0$ and $F^{0i}=-F^{i0}$, this reduces to:

$$F_{\alpha\beta}=(\eta_{\alpha i}\eta_{\beta0}-\eta_{\alpha0}\eta_{\beta i})F^{i0}+\eta_{\alpha i}\eta_{\beta j}F^{ij}\qquad(6.7.238)$$

Now for $\alpha=0,\beta=k=1,2,3$:

$$\begin{aligned}F_{0k}&=(\eta_{0i}\eta_{k0}-\eta_{00}\eta_{ki})F^{i0}+\eta_{0i}\eta_{kj}F^{ij}\\&=(0-(-\delta_{ki}))F^{i0}+0\\&=F^{k0}=-F^{0k}\end{aligned}\qquad(6.7.239)$$

and by antisymmetry, for $\alpha=k=1,2,3$, $\beta=0$:

$$F_{0k}=-F_{k0}\qquad(6.7.240)$$

then finally for $\alpha=k=1,2,3$, $\beta=\ell=1,2,3$:

$$\begin{aligned}F_{k\ell}&=(\eta_{ki}\eta_{\ell0}-\eta_{k0}\eta_{\ell i})F^{i0}+\eta_{ki}\eta_{\ell j}F^{ij}\\&=0+\delta_{ki}\delta_{\ell j}F^{ij}\\&=F^{k\ell}\end{aligned}\qquad(6.7.241)$$

The (covariant) lower indexed tensor is then:

$$F_{\alpha\beta}=\begin{pmatrix}0&E_x/c&E_y/c&E_z/c\\-E_x/c&0&-B_z&B_y\\-E_y/c&B_z&0&-B_x\\-E_z/c&-B_y&B_x&0\end{pmatrix}\qquad(6.7.242)$$

E3. We will also see further below an example where we contract a tensor of order 1 (one of the contravariant components of the vectors of the spherical base) having already a lowered index:

$$\left.\begin{aligned}\omega_3^3&=\frac{\mathrm{d}r}{r}+\cot(\theta)\mathrm{d}\theta\\g_{ij}&=\begin{bmatrix}1&0&0\\0&r^2&0\\0&0&r^2\sin^2(\theta)\end{bmatrix}\end{aligned}\right\}\Rightarrow\begin{aligned}\omega_{33}&=g_{33}\omega_3^3=r^2\sin^2(\theta)\left(\frac{\mathrm{d}r}{r}+\cot(\theta)\mathrm{d}\theta\right)\\&=r^2\sin^2(\theta)\mathrm{d}r+r^2\sin^2(\theta)\cos(\theta)\mathrm{d}r\mathrm{d}\theta\end{aligned}\qquad(6.7.243)$$

Remarks

R1. In the relation:

$$g_{i_1j_1}u^{i_1i_2i_3\ldots i_p}=u_{j_1}^{i_2i_3\ldots i_p}=u_k^{ki_3\ldots i_p}=v^{i_3\ldots i_p}\qquad(6.7.244)$$

the equality is an abusive notation that we can find in some books (because strictly speaking we should do the calculation in two steps).

R2. As a result of the symmetry of the quantities g_{ij} (the dot product is commutative), this latter tensor is identical to what we would get by lowering to the covariant position the index i_2, and then by doing the contraction of the index i_1 with the index j_2.

Let see this:

The symmetry $g_{ij} = g_{ji}$ takes the form (this may seem confusing but let us remember that the number of the component i indicates the place of this component):

$$g_{i_1 j_1} = g_{i_2 j_2} \tag{6.7.245}$$

Therefore it comes:

$$g_{j_2 i_2} u^{i_1 i_2 i_3 \ldots i_p} = u_{j_2}^{i_1 i_3 \ldots i_p} \tag{6.7.246}$$

and putting $i_1 = j_2 = k$:

$$v^{i_3 i_4 \ldots i_p} = u_k^{k i_3 \ldots i_p} \tag{6.7.247}$$

In general, the contraction of a tensor allows to form a tensor of order $p-2$ from a tensor of order p. We can of course repeat the operation of contraction. Thus, an even tensor, $2p$, will become a scalar after p contractions and an odd order tensor $2p+1$, will become a vector.

We can extend after this definition of the contraction of indices, the tensoriality criterion. We have seen until now two ways to recognize the character of a tensor of a sequence of quantities:

- The first is to show that these quantities are formed by the tensor product of component vectors or by a sum of tensor products;
- The second is to study how these quantities are converted during a basis change and to check the conformity of the relations of transformation;
- The third and new one that brings to put that for a set of n^{p+1} quantities, having p upper and q lower indexes to be a tensor, it is necessary and sufficient that their product fully contracted by the contravariant components of any p vectors and the covariates components of any q vectors, to be a quantity (the norm in fact...) that remains invariant under basis change.

6.7.8 Special Tensors

We may face in theoretical physics and engineering with tensors that have interesting properties. To avoid redundant work in each case, we will list here and proved the various existing properties used in this textbook in other sections and discuss their possible implications briefly (the detailed analysis being reserved for their application in the other same sections of the book).

6.7.8.1 Symmetric Tensor

Consider a tensor $\vec{T}$ of order two of contravariant components T^{ij}. Let us suppose that, following a base $(\vec{e}_i)$, all these components satisfy the relations:

$$T^{ij}=T^{ji} \tag{6.7.248}$$

On another base $(\vec{e}\,'_j)$, related to the previous by the known transformation relations, the new components of T'^{lm} satisfy the relation:

$$T'^{lm}=A'^{l}_{i}A'^{m}_{j}T^{ij}=A'^{m}_{j}A'^{l}_{i}T^{ji} \tag{6.7.249}$$

We see that the property $T^{ij}=T^{ji}$ is therefore an intrinsic characteristic of the tensor $\vec{T}$, independent of the base! We then say that the tensor is a "symmetric tensor" (we will come back again on this concept a little further below) also named "totally invariant tensor" (implicitly meaning: by base change).

The symmetry property is also true for the covariant components of a symmetric tensor since we have:

$$T_{lk}=g_{li}g_{kj}T^{ij}=g_{kj}g_{li}T^{ji}=T_{kl} \tag{6.7.250}$$

Conversely, the symmetry of the covariant components implies that of the contravariant components.

For higher order tensor, the symmetry may be partial, being valid only for two covariant indices or two contravariant indices. Thus, a fourth order tensor, of mixed components T_l^{ijk}, may also be symmetrical in i and j, for example, given:

$$T_l^{ijk}=T_l^{jik} \tag{6.7.251}$$

We check, as above, that such a property is intrinsic.

A tensor is said to be "completely symmetrical tensor" if any transposition of two indices with the same variance, changes the corresponding component into itself. For example, for a tensor of order three T^{ijk}, completely symmetric, we have the following components that are equal:

$$T^{ijk}=T^{jik}=T^{kji}=T^{ikj} \tag{6.7.252}$$

There are many examples of symmetric tensors. Some include:

- the metric tensor $g_{\mu\nu}$ (see section General Relativity page 5731)

- the Einstein tensor $G_{\mu\nu}$ (see further below)
- the Ricci tensor $R_{\mu\nu}$ (see also further below)
- the stress and strain tensor for fluids or solids σ_{ij} (see section Continuum Mechanics page 3815)
- the Lorentz boost tensor Γ_{ν}^{μ} (see section Special Relativity page 5638)
- ...

We can also (very interesting curiosity) obtain a geometric representation of the values of the components of a symmetric tensor of order two!!

For this let us, consider in the ordinary geometric space coordinates x^i, the following equation:

$$a_{ij}x^ix^j=1 \tag{6.7.253}$$

where, for recall, x^ix^j can be seen as a tensor with $i,j=1,2,3$ and where the a_{ij} are real given coefficients. Let us suppose that coefficients are such that:

$$a_{ij}=a_{ji} \tag{6.7.254}$$

The above equation is then:

$$a_{11}x_1^2+a_{22}x_2^2+a_{33}x_3^2+2a_{12}x_1x_2+2a_{23}x_2x_3+2a_{31}x_3x_1=1 \tag{6.7.255}$$

Here we fall back on the equation of a surface of the second degree of a quadratic similar to of the plan that we saw in the section of Analytical Geometry (see page 2765). We know by extension into three dimensions that these surfaces are ellipsoids or hyperboloids, depending to the values of the quantities a_{ij}.

Let us study how the quantities a_{ij} transform when we make a change of coordinates such as:

$$x'^k={A'}^k_ix^i \qquad \text{and} \qquad x^i=A^i_kx'^k \tag{6.7.256}$$

The equation of the quadric is written in this new coordinate system:

$$a_{ij}A^i_kA^j_mx'^kx'^m={a'}_{km}x'^kx'^m=1 \tag{6.7.257}$$

Hence the expression of the coefficients in the new system of axes:

$${a'}_{km}=A^i_kA^j_ma_{ij} \tag{6.7.258}$$

The coefficients a_{ij} therefore transform as the covariant components of a tensor of order two. Conversely, if the quantities a_{ij} are the components of a symmetric tensor, these components define the coefficients of a quadric!! There is therefore a certain equivalence between a symmetric tensor and the coefficients of a quadratic...!!! We say then that the equation of the quadric is the "quadric representation of a symmetric tensor" or "representation surface".

So the representation surface (or representation quadric) is a geometrical representation of a second rank symmetric tensor and is useful for giving us a visual image of the tensor as well as being useful for example in calculating magnitudes of material properties described by second rank symmetric tensors!!

We know from our study of quadrics in the section of Analytical Geometry (by extending it to the three-dimensional case) that we can always find a coordinate system relative to which the equation of a quadratic takes a simpler form:

$$b_1x_1^2+b_2x_2^2+b_3x_3^2=1 \tag{6.7.259}$$

In this case, the basis vectors are supported by the main axes of the quadric. In this coordinate system, the components of the tensor equation reduce to:

$$a_{11}=b_1 \qquad a_{22}=b_2 \qquad a_{33}=b_3 \tag{6.7.260}$$

and $a_{ij}=0$ for the other components. The quantity b_i equation are named the "principal values" of the tensor a_{ij}.

If the quantities b_1,b_2,b_3 are positive, the surface is an ellipsoid, if two quantities are strictly positive and the third strictly negative, we have a one sheet hyperboloid, if two quantities are strictly negative and the third positive, we have two sheets hyperboloid (see section Analytical Geometry page 2844).

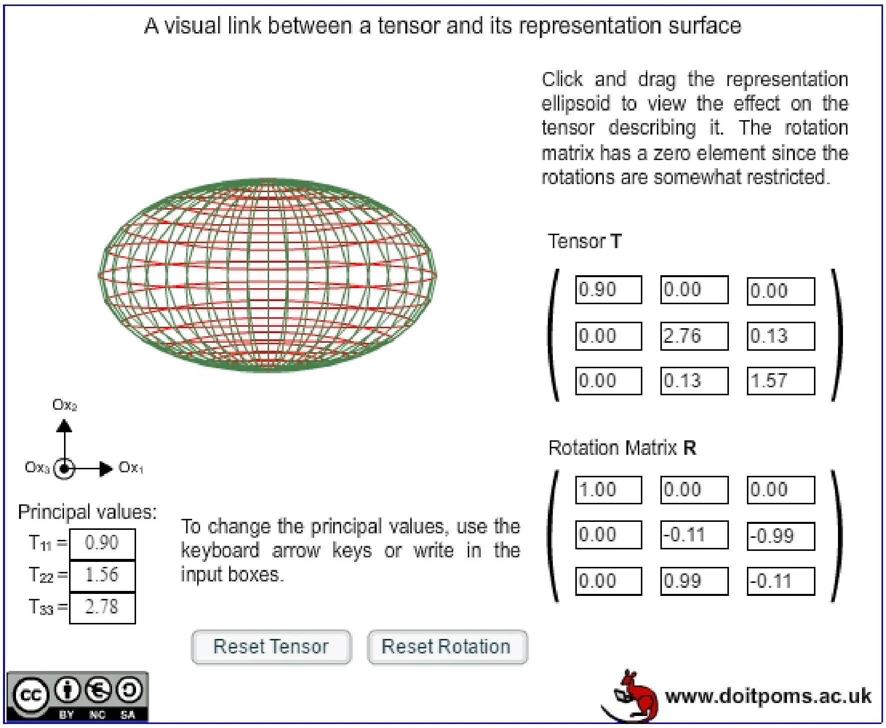
Comparing the expression of the quadric obtained previously with the classic equation:

$$\frac{x_1^2}{a^2}+\frac{x_2^2}{b^2}+\frac{x_3^2}{c^2}=1 \tag{6.7.261}$$

where a, b, c are the semi-axes of an ellipsoid shows that we have:

$$a=\frac{1}{\sqrt{b_1}} \qquad b=\frac{1}{\sqrt{b_2}} \qquad c=\frac{1}{\sqrt{b_b}} \tag{6.7.262}$$

Below we can see a screen shot of an interactive tool of Cambridge University to play with the ellipticity (only!) representation quadric of a rank two symmetric tensor:



A visual link between a tensor and its representation surface

Click and drag the representation ellipsoid to view the effect on the tensor describing it. The rotation matrix has a zero element since the rotations are somewhat restricted.

Tensor **T**

$$\begin{pmatrix} 0.90 & 0.00 & 0.00 \\ 0.00 & 2.76 & 0.13 \\ 0.00 & 0.13 & 1.57 \end{pmatrix}$$

Rotation Matrix **R**

$$\begin{pmatrix} 1.00 & 0.00 & 0.00 \\ 0.00 & -0.11 & -0.99 \\ 0.00 & 0.99 & -0.11 \end{pmatrix}$$

Principal values:

T_{11} = 0.90
T_{22} = 1.56
T_{33} = 2.78

To change the principal values, use the keyboard arrow keys or write in the input boxes.

Figure 6.158: **Visual link between a tensor and its representative surface (source: http://www.doitpoms.ac.uk)**

6.7.8.2 Antisymmetric Tensor

When the contravariant or covariant components of a tensor of order two, satisfy the property:

$$T^{ij} = -T^{ji} \tag{6.7.263}$$

we then say that the tensor is a "antisymmetric tensor" (the same applies if the components are covariant). In other words a tensor is antisymmetric on (or with respect to) an index subset if it alternates sign $(+/-)$ when any two indices of the subset are interchanged.

It is an intrinsic property of the tensor which is proved as for the symmetric tensors, to a given "-" sign. A contravariant tensor of order two, thus verifying the following relation, will be named a "symmetric tensor" (we have already mentioned it a bunch of times in the previous paragraphs).

It follows from this definition that an antisymmetric tensor must obviously satisfy the fact that its diagonal components are all zero, such as for example for a rank 2 tensor:

$$T^{11} = T^{22} = \ldots = T^{nn} = 0 \tag{6.7.264}$$

A well known antisymmetric tensor is the electromagnetic tensor $F_{\mu\nu}$ (see section Electrodynamics page 4121).

For example a covariant tensor of order three T_{ijk} will be say to be symmetric in i and k if for all values that can take the indices, we have:

$$T_{ijk} = T_{kji} \tag{6.7.265}$$

Or the fourth order covariant tensor T_{ijkl} will be said in antisymmetric on i and l if for all values that can take the indices, we have:

$$T_{ijkl} = -T_{ljki} \tag{6.7.266}$$

A tensor will "totally antisymmetric" if any transposition of index of same variance (covariant/contravariant) changes the corresponding component into its opposite.

A tensor T_{ij} can be put in the form of a sum of a symmetric tensor and an antisymmetric tensor. Indeed, we have:

$$\boxed{T_{ij} = \frac{1}{2}(T_{ij} + T_{ji}) + \frac{1}{2}(T_{ij} - T_{ji})} \tag{6.7.267}$$

The first term of the sum above is a symmetric tensor and the second, an antisymmetric tensor.

Proof 6.45.10. Consider first that T_{ij} is symmetric, then we have:

$$T_{ij} = \frac{1}{2}(T_{ij} + T_{ji}) + \frac{1}{2}\underbrace{(T_{ij} - T_{ji})}_{=0} = \frac{1}{2}(T_{ij} + T_{ji}) = \frac{1}{2}(T_{ij} + T_{ij}) = \frac{1}{2}T_{ij} = T_{ij} \tag{6.7.268}$$

So this proves that the left term is indeed symmetric for this special case.

Consider secondly that T_{ij} is symmetric, then we have:

$$T_{ij}=\frac{1}{2}\underbrace{(T_{ij}+T_{ji})}_{=0}+\frac{1}{2}(T_{ij}-T_{ji})=\frac{1}{2}(T_{ij}-T_{ji})=\frac{1}{2}2T_{ij}=T_{ij} \tag{6.7.269}$$

So this proves that the left term is indeed antisymmetric for this special case.

Now if T_{ij} is neither symmetric or antisymmetric we have:

$$T_{ij}=\frac{1}{2}(T_{ij}+T_{ji})+\frac{1}{2}(T_{ij}-T_{ji})=\frac{1}{2}T_{ij}+\frac{1}{2}T_{ji}+\frac{1}{2}T_{ij}-\frac{1}{2}T_{ji}=\frac{1}{2}2T_{ij}+\frac{1}{2}(T_{ji}-T_{ji})=\frac{1}{2}T_{ij} \tag{6.7.270}$$

■ Q.E.D.

A tensor T_l^{ijk} will be "partially antisymmetric if for example we have:

$$T_l^{ijk}=-T_l^{jik} \tag{6.7.271}$$

That is to say antisymmetric only for a subset of indices.

Let us now consider two vectors $\vec{x}=x^i\vec{e}_i$ and $\vec{y}=y^j\vec{e}_j$ of a vector space $\mathcal{E}^n$. Let us form the following antisymmetric quantities (we can see in it two tensor products):

$$T^{ij}=x^iy^j-x^jy^i \tag{6.7.272}$$

where we see immediately that the components T^{ij} are those of an antisymmetric tensor $\vec{T}$ by construction as:

$$x^iy^j-x^jy^i=-(x^jy^i-x^iy^j) \tag{6.7.273}$$

The decomposition of the vector $\vec{T}$ in the base $\vec{e}_i\vec{e}_j$ is:

$$\vec{T}=(\vec{x}\times\vec{y})=(x^iy^j-x^jy^i)\vec{e}_i\otimes\vec{e}_j=\vec{x}\otimes\vec{y}-\vec{y}\otimes\vec{x} \tag{6.7.274}$$

The tensor $\vec{x}\otimes\vec{y}$ (written as it in analogy to the vectors cross product for $n=3$) is named the "outer product" of the vectors $\vec{x}$ and $\vec{y}$. We say that this tensor is a "bivector".

The outer product is an antisymmetric tensor which satisfies the following properties:

P1. Anti-commutativity:

$$\vec{x}\times\vec{y}=-\vec{y}\times\vec{x} \tag{6.7.275}$$

the result is:

$$\vec{x}\times\vec{x}=\vec{0} \tag{6.7.276}$$

P2. Left and right distributivity for the vector addition:

$$\begin{aligned}\vec{x}\times(\vec{y}+\vec{z})&=\vec{x}\times\vec{y}+\vec{x}\times\vec{z}\\(\vec{x}+\vec{y})\times\vec{y}&=\vec{x}\times\vec{z}+\vec{y}\times\vec{z}\end{aligned} \tag{6.7.277}$$

P3. Associativity for the multiplication by a scalar:

$$\alpha\vec{x}\times\vec{y}=\vec{x}\times\alpha\vec{y}=\alpha(\vec{x}\times\vec{y}) \tag{6.7.278}$$

P4. Outer products:

$$\vec{e}_i\times\vec{e}_j=\vec{e}_i\otimes\vec{e}_j-\vec{e}_j\otimes\vec{e}_i \tag{6.7.279}$$

constitute a base for all bivectors.

Proof 6.45.11. An antisymmetric tensor $\vec{T}$ of order two, element of $\mathcal{E}^2_{(2)}$ can, as we have proved it earlier, be written as:

$$\vec{T}=T^{ij}\vec{e}_i\otimes\vec{e}_j=\sum_{i<j}T^{ij}\vec{e}_i\otimes\vec{e}_j+\sum_{i\geq j}\vec{e}_i\otimes\vec{e}_j \tag{6.7.280}$$

Exchanging, in the last sum of the above relation, the name of the indices and considering that $T^{ij}=-T^{ji}$, we get:

$$\vec{U}=\sum_{i<j}u^{ij}(\vec{e}_i\otimes\vec{e}_j-\vec{e}_j\otimes\vec{e}_i) \tag{6.7.281}$$

The elements:

$$\vec{e}_i\otimes\vec{e}_j-\vec{e}_j\otimes\vec{e}_i \tag{6.7.282}$$

are linearly independent vectors since the vectors $\vec{e}_i\otimes\vec{e}_j$ also are it. These elements constitute a base on which the antisymmetric tensor can be decomposed.

■ Q.E.D.

The number of distinguishable vectors $\vec{e}_i\otimes\vec{e}_j-\vec{e}_j\otimes\vec{e}_i$ is equal to the number of combinations of vectors taken two by two and distinguishable among n such that (see section Probabilities page 528):

$$C_2^n=\frac{n!}{2!(n-2)!}=\frac{n(n-1)}{2}<n^2 \tag{6.7.283}$$

Indeed among the n^2 components, n components are equal to zero and $n(n-1)$ other components have opposed values to two by two. So we can consider that half of the latter is sufficient to characterize the tensor.

In the context of the outer tensor product where we have:

$$T^{ij}=x^iy^j-x^jy^i \tag{6.7.284}$$

the number of distinguishable components is also equal to $n(n-1)/2$ and they are named "strict components".

We notice that for $n=3$, the strict number of components of the outer product of two vectors is also equal to three. This allows to form, with the components of the bivector, the components of a cross product $\vec{z}$.

Thus, a cross product therefore exists only for a subspace of bivectors whose number of dimensions is equal to 3 and the pre-images that are antisymmetric tensors.

If all these conditions are satisfied, we say that the vector $\vec{z}$ is the "adjoint tensor" of tensor $\vec{T}$.

6.7.8.3 Fundamental Tensor

We saw at the beginning of our study of Tensor Calculus the definition of the components of the fundamental covariant tensor g_{ij}, that is for recall:

$$g_{ij}=\vec{e}_i\circ\vec{e}_j \tag{6.7.285}$$

These quantities are involved, as we know it (see previous topics), in the expression of the dot product of two vectors $\vec{x}$ and $\vec{y}$ of contravariant components x^i and y^i, given by the relation (for recall):

$$\vec{x}\circ\vec{y}=g_{ij}x^iy^i \tag{6.7.286}$$

Let us use the general test of tensoriality to highlight the tensor character of the g_{ij}. The previous expression is a product fully contracted of the quantities g_{ij} with the contravariant components x^iy^i of an arbitrary tensor. As the dot product is an invariant quantity (in this case a scalar) with respect to the base changes, it follows that the n^2 quantities g_{ij} are the covariant components of a tensor.

This tensor is also symmetrical as a result of the symmetry property of the dot product of the basis vectors such that:

$$g_{ij}=g_{ji} \tag{6.7.287}$$

We have the same for the contravariant components of the fundamental tensor:

$$g^{ij}=g^{ji} \tag{6.7.288}$$

If we denote by g_j^i the mixed components of a fundamental tensor to himself:

$$g_j^i=g^{ik}g_{jk} \tag{6.7.289}$$

obviously with the canonical basis:

$$g_j^i=\delta_j^i \tag{6.7.290}$$

6.7.9 Curvilinear Coordinates

The conventional concepts of coordinate system can be generalized as we know to any specific n-dimensional punctual space (see section Principia page 3145). We name "coordinate system" in $\mathcal{E}^n$, any mode of definition of a point M in the considered system.

Definitions (#6.7.265):

D1. For a given coordinates system (Cartesian, spherical, cylindrical, polar ...) system we name "coordinate line" the "place" of the points M when a only single coordinate of M varies, the other being keep as constant.

D2. A "curvilinear coordinates" are a coordinate system for Euclidean space in which the coordinate lines may be curved. These coordinates may be derived from a set of Cartesian coordinates by using a transformation that is locally invertible (a one-to-one map) at each point (see section Vector Calculus page 1846).

This means that one can convert a point given in a Cartesian coordinate system to its curvilinear coordinates and back. The purpose as we already know is that depending on the application, a curvilinear coordinate system may be simpler to use than the Cartesian coordinate system. For instance, a physical problem with spherical symmetry defined (for example, motion of particles under the influence of central forces) is usually easier to solve in spherical polar coordinates than in Cartesian coordinates.

Well-known examples of curvilinear coordinate systems are as we know in three-dimensional Euclidean space the Cartesian, cylindrical and spherical polar coordinates.

Let us first study the generalization of a coordinate system relative to a fixed reference frame (we urge the reader to consult first the subsection about Coordinate Systems in the section of Vector Calculus and the subsection of Analytical Mechanics in the section Principia).

Let us consider a punctual space $\mathcal{E}^n$ and $(\vec{e}_i)$ a reference frame of that space. Given x_i the rectilinear coordinates of a point M of $\mathcal{E}^n$ relatively to this reference frame. Any curvilinear coordinate system u^k, with $k=1,2,\ldots,n$, is obtained by giving n arbitrary functions f^i of parameters u^k, such that:

$$x^i = f^i(u^1,u^2,\ldots,u^n) \tag{6.7.291}$$

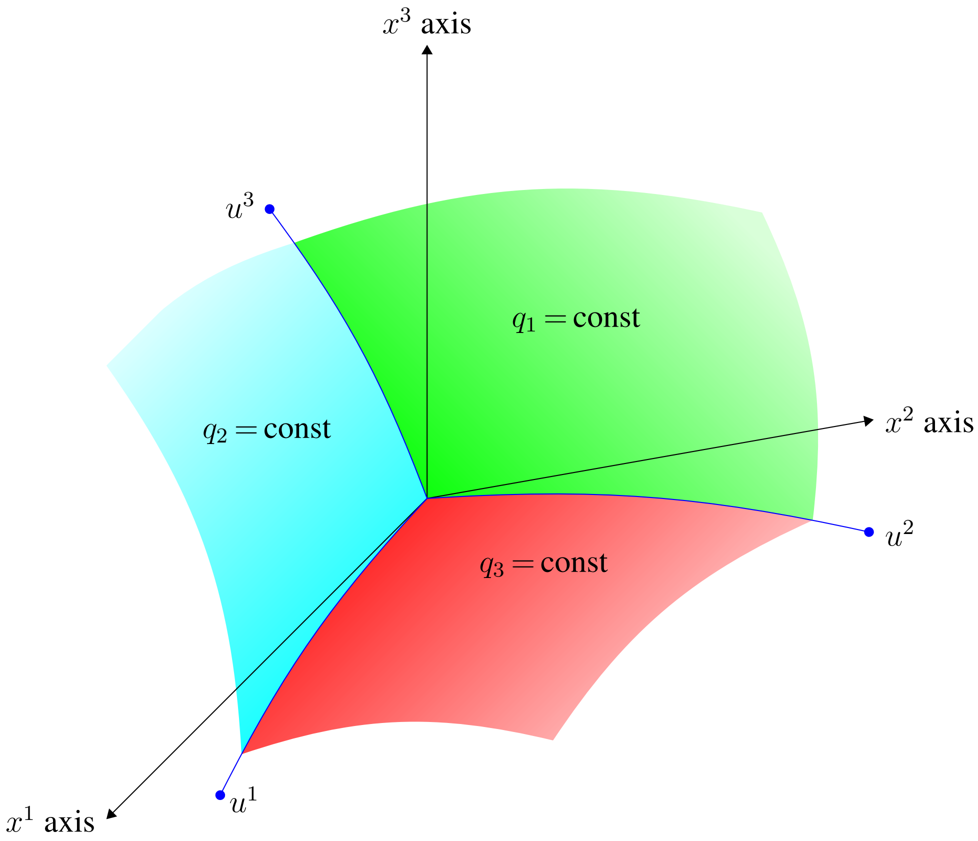


Figure 6.159: **Coordinate surfaces, coordinate lines and coordinate axes of general curvilinear coordinates (source: Wikipedia, author: Lyudmil Antonov)**

We will assume thereafter that these n functions satisfy the following three properties:

P1. They must be of class at least $\mathcal{C}^2$ (differentiable at least twice for the needs of physics: speed and acceleration). This assumption implies, that at any point where it is satisfied, that we have the permutation of derivations (with respect to the two partial derivatives as seen in the section of Differential and Integral Calculus):

$$\partial_{kl} f^i = \partial_{lk} f^i \tag{6.7.292}$$

where for reminder:

$$\frac{\partial f^a}{\partial x^b} = \lim_{h \to 0} \frac{V^a\left(\ldots, x^b + h, \ldots\right) - V^a\left(\ldots, x^b, \ldots\right)}{h} = \partial_b V^a \tag{6.7.293}$$

with $V^a = \vec{V} \cdot \vec{e}^a$.

P2. These functions are such that we can solve the system of n equations of coordinate system change relatively to the variables u^k and express them in function of the parameters x^i, thus:

$$u^k = g^k(x^1, x^2, \ldots, x^n) \tag{6.7.294}$$

still with $k = 1, 2, \ldots, n$.

P3. When the variables u^k vary in a domain Δ, the variables x^i vary in a domain Δ' (think to cartesian↔ spherical coordinates where in cartesian the variable range is infinite when in spherical both of them are limited a typical 2π width range).

P4. The Jacobian of the functions $x^i=f^i(u^1,u^2,\ldots,u^n)$, defined by (see section Differential and Integral Calculus page 1524):

$$\mathrm{D}(\partial_k x^i)=\begin{bmatrix}\partial_1 x^1 & \partial_1 x^2 & \ldots & \partial_1 x^n\\ \partial_2 x^1 & \partial_2 x^2 & \ldots & \partial_2 x^n\\ \ldots & \ldots & \ldots & \ddots\\ \partial_n x^1 & \partial_n x^2 & \ldots & \partial_n x^n\end{bmatrix} \tag{6.7.295}$$

will be assumed different from zero in the domain Δ (and also the Jacobian $\mathrm{D}(\partial_i u^k)$ of the functions $u^k=g^k(x^1,x^2,\ldots,x^n)$) and is the inverse of the Jacobian of $u^k=g^k(x^1,x^2,\ldots,x^n)$. If the jacobians exist, they are not zero as a result primarily of the second property above and implicitly the first.

As we have already mention if we fix $(n-1)$ parameters u^k by varying only one parameter, u^i for example, we get the coordinates $x^i_{(1)}$ of a set of points M that constitute a "coordinate line line". In general, the coordinate lines are not straight but curved as we know. These coordinates u^k are named for this reasons the "curvilinear coordinates". On a point M of $\mathcal{E}^n$ intersect elsewhere n coordinate lines.

We proved in the section of Analytical Mechanics, during our study of punctual spaces (see page 3145), that partial derivatives of a vector $\overrightarrow{\mathrm{O}M}$ of $\mathcal{E}^n$ are independent of the point O (origin) of a given reference frame. If $\mathcal{E}^n$ is assimilated to a system of curvilinear coordinate u^k, we write:

$$\boxed{\vec{e}_k=\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial u^k}=\partial_k\vec{M}} \tag{6.7.296}$$

✍**Example:**

A famous example of curvilinear coordinates u^k, where each u^k is a uniform function of the rectilinear coordinates x^k, the u^k being moreover continuous functions at the point M, is that of the spherical coordinates where we have (see section Vector Calculus page 1849):

$$u^1=r \qquad u^2=\theta \qquad u^3=\phi \tag{6.7.297}$$

and where for recall:

$$x_1=r\sin(\theta)\cos(\phi) \qquad x_2=r\sin(\theta)\sin(\phi) \qquad x_3=r\cos(\theta) \tag{6.7.298}$$

Let us also recall that during our study of the system of spherical coordinates in the section of Vector Calculus we obtained after normalization of the basis vector:

$$\mathrm{d}\vec{M}=\vec{e}_r\mathrm{d}r+\vec{e}_\theta r\mathrm{d}\theta+\vec{e}_\phi r\sin(\theta)\mathrm{d}\phi \tag{6.7.299}$$

Therefore:

$$\frac{\partial\vec{M}}{\partial r}=\vec{e}_r \qquad \frac{\partial\vec{M}}{\partial\theta}=\vec{e}_\theta r \qquad \frac{\partial\vec{M}}{\partial\phi}=\vec{e}_\phi r\sin(\theta) \tag{6.7.300}$$

with:

$$\left\|\frac{\partial\vec{M}}{\partial r}\right\|=1 \qquad \left\|\frac{\partial\vec{M}}{\partial\theta}\right\|=r \qquad \left\|\frac{\partial\vec{M}}{\partial\phi}\right\|=r\sin(\theta) \tag{6.7.301}$$

In a non-Euclidean space, we can not define a unique valid basis over the whole space. Thus, we construct a base at each point separately and for this purpose we use the curvilinear coordinates such that at each point M, the base vectors $\vec{e}_k$ are tangent to the corresponding coordinate line equation via the relation given above:

$$\vec{e}_k=\frac{\partial\overrightarrow{\text{O}M}}{\partial u^k}=\partial_k\vec{M} \tag{6.7.302}$$

Given now $u^1,u^2,\ldots,u^n$ the curvilinear coordinates of the point M with respect to a Cartesian basis $(\vec{e}_i^{\,0})$. In this reference frame, we obviously have:

$$\overrightarrow{\text{O}M}=x^i\vec{e}_i^{\,0} \tag{6.7.303}$$

where the Cartesian coordinates are functions $x^i=x^i(u^1,u^2,\ldots,u^n)$.

The vector $\vec{e}_k$ can therefore also be expressed by:

$$\vec{e}_k=\partial_k(x^i\vec{e}_i^{\,0})=(\partial_k x^i)\vec{e}_i^{\,0} \tag{6.7.304}$$

The reader can check with the example of spherical coordinates (by looking to the explicit version of the corresponding vectors in the section of Vector Calculus) that this relation is correct but at the condition that we work with the non-normalized version of the orthogonal vectors $\vec{e}_r$, $\vec{e}_\theta$, $\vec{e}_\phi$!

From the components $\partial_k x^i$ of the vector $\vec{e}_k$, we can form a determinant $\det(\partial_k x^i)$ which is precisely the Jacobian of the of the functions x^i we have defined previously. Since this determinant is different from zero (at least imposed as such), it follows that the n vectors $\vec{e}_k$ (as functions) are linearly independent (we have proved in the section of Differential and Integral Calculus that this Jacobian is in absolute value equal to $r^2\sin(\theta)$ for the spherical coordinates).

Remark

Let us recall that in the section of Differential and Integral Calculus we have proved that the determinant of the Jacobian appears when calculating the surface of a parallelogram in a non-euclidean space. Obviously is the determinant is zero, then the surface is zero as it means that the vector basis of the parallelogram are all collinear (linearly dependants). Hence the fact that if the determinant is not null then some of the vectors (or all) are independent!

These n vectors, defined by the relation:

$$\vec{e}_k=\partial_k\vec{M} \tag{6.7.305}$$

are named the "natural basis" at the point M of the vector space $\mathcal{E}^n$. They are collinear to the tangents of the n coordinated lines which intersect at the point M where they are defined.

We will not insist on the quite obvious fact that at each system of curvilinear coordinates there is an associated natural basis whose base is expressed by these same coordinates (see section Vector Calculus page 1846).

✍**Example:**

In spherical coordinates, the vectors of the natural basis are those that we obtained in our study of the spherical coordinate system in the section of Vector Calculus and that are orthogonal but not orthonormal.

Let us associate at the point M of $\mathcal{E}^n$ a reference frame formed by the point M and by the vectors of the natural basis[32]. This reference frame is named the "natural reference frame" on M of the coordinate system u^k. It will be denoted by:

$$(M,\vec{e}_k) \qquad \text{or} \qquad (M,\partial_k\vec{M}) \tag{6.7.306}$$

The differential of the vector $\overrightarrow{\mathrm{O}M}$ is then expressed as:

$$\mathrm{d}\vec{M}=\partial_k\vec{M}\mathrm{d}u^k=\vec{e}_k\mathrm{d}u^k \tag{6.7.307}$$

The quantities $\mathrm{d}u^k$ are (obviously) the contravariant components of the vector $\mathrm{d}\vec{M}$ in the natural reference frame $(M,\vec{e}_k)$ of the coordinate system u^k.

Let us now consider any two curvilinear coordinate systems u^i and u^k (think for example to the spherical and cylindrical coordinate systems), linked between them by the relations:

$$u^i=u^i\left(u'^1,u'^2,\ldots,u'^n\right) \qquad u'^k=u'^k\left(u^1,u^2,\ldots,u^n\right) \tag{6.7.308}$$

where the functions $u^i=u^i(u'^1,u'^2,\ldots,u'^n)$ are assumed as we already know to be several times continuously differentiable with respect to the u'^k and same for the functions $u'^k=u'^k(u^1,u^2,\ldots,u^n)$ with respect the coordinates u^i. When we move from one coordinate system to another, we say that we make a "change of curvilinear coordinates".

We saw that in the sections of Differential Geometry and General Relativity that the squared distance $\mathrm{d}s$ between two points M and M' infinitely close was given by the relation:

$$\boxed{\mathrm{d}s^2=g_{ij}\mathrm{d}x^i\mathrm{d}x^j} \tag{6.7.309}$$

where the $\mathrm{d}x^i$ are the components of the vector $\mathrm{d}\vec{M}=\overrightarrow{MM}$, assimilated to a fixed reference frame of a punctual space $\mathcal{E}^n$. When this space is assimilated to a system of curvilinear coordinates u^i, we have seen that the relation:

$$\mathrm{d}\vec{M}=\partial_k\vec{M}\mathrm{d}u^k=\vec{e}_k\mathrm{d}u^k \tag{6.7.310}$$

shows that the vector $\mathrm{d}\vec{M}$ has for curvilinear contravariant components the quantities $\mathrm{d}u^i$ with respect to the natural base $(M,\vec{e}_i$. The square of the distance $\mathrm{d}s^2$ (i.e. the "line-elements") is then written in the natural reference frame:

$$\mathrm{d}s^2=g_{ij}\mathrm{d}u^i\mathrm{d}u^j \tag{6.7.311}$$

---

[32] For recall that natural basis in an Euclidean space is the set of unit vectors pointing in the direction of the axes of a Cartesian coordinate system

Where the quantities $g_{ij}=\vec{e}_i\circ\vec{e}_j$ are the components of the "fundamental tensor" or of "metric tensor" defined using a natural base. The previous expression is named the "linear element of the point space" $\mathcal{E}^n$ or sometimes the "metric" of this space.

The vectors $\vec{e}_i$ of the natural reference frame generally vary from one point to another. This is the case, for example, of the spherical coordinates whose quantities g_{ij} (we show it afterwards with a detailed example) are variable since depending on the parameters r, θ or ϕ!

A curve Γ of $\mathcal{E}^n$ can be defined by the data of the curvilinear coordinates $u^i(\alpha)$ of the locus of the points $M(\alpha)$ as a function of a parameter α (see section Differential Geometry page 2850). The elementary distance $\mathrm{d}s$ on this curve Γ is then written:

$$\mathrm{d}s=\left[g_{ij}\frac{\partial u^i}{\partial\alpha}\frac{\partial u^j}{\partial\alpha}\right]^{1/2}\mathrm{d}\alpha \tag{6.7.312}$$

Let us consider a tangent vector $\vec{v}$ of Γ and denote its components v^i on a basis $\vec{e}_i$. On another basis $\vec{e}_i'$ we denote the components v'^i, so:

$$\vec{v}=v^i\vec{e}_i=v'^i\vec{e}_i' \tag{6.7.313}$$

in which:

$$v^i=\frac{\mathrm{d}x^i}{\mathrm{d}\alpha}\text{ and }v'^i=\frac{\mathrm{d}x^{ii}}{\mathrm{d}\lambda} \tag{6.7.314}$$

If we express the new components in terms of the old ones, then:

$$v'^i=\frac{\mathrm{d}x'^i}{\mathrm{d}\alpha}=\frac{\partial x'^i}{\partial x^j}\frac{\mathrm{d}x^j}{\mathrm{d}\alpha}=\frac{\partial x'^i}{\partial x^j}v^j \tag{6.7.315}$$

This is the explicit form of a transformation named the "contravariant transformation". In order to distinguish them such vectors from the covariant (tangent) vectors, the index is placed on top.

A famous example of a contravariant transformation is given by a differential form $\mathrm{d}f$. For f as a function of coordinates x^i, $\mathrm{d}f$ can be expressed in terms of $\mathrm{d}x^i$ (i.e. the total derivative). The differentials $\mathrm{d}x^i$ transform according to the contravariant rule since:

$$\boxed{\mathrm{d}x'^i=\frac{\partial x'^i}{\partial x^j}\mathrm{d}x^j} \tag{6.7.316}$$

6.7.9.1 Natural basis in spherical coordinates (curvilinear basis in spherical coordinates)

Let us determine the natural basis of the vector space E^3 associated with the point space $\mathcal{E}^3$ of ordinary geometry, in spherical coordinates. Let us write the expression of the vectors $\overrightarrow{\text{O}M}$ in a fixed cartesian basis $(\vec{e}_i^{\,0})$ which is by definition (see the section Vector Calculus for more details):

$$\overrightarrow{\text{O}M}=x^i\vec{e}_i^{\,0}=r\sin(\theta)\cos(\phi)\vec{e}_1^{\,0}+r\sin(\theta)\sin(\phi)\vec{e}_2^{\,0}+r\cos(\theta)\vec{e}_3^{\,0} \tag{6.7.317}$$

The vectors of the natural base are given by:

$$\vec{e}_k=\partial_k\vec{M}\Rightarrow\begin{cases}\vec{e}_1=\partial_1\vec{M}=\partial_r\vec{M}\\ \vec{e}_2=\partial_2\vec{M}=\partial_\theta\vec{M}\\ \vec{e}_3=\partial_3\vec{M}=\partial_\phi\vec{M}\end{cases}\tag{6.7.318}$$

Therefore we have:

$$\vec{e}_1=\partial_1\vec{M}=\sin(\theta)\cos(\phi)\vec{e}_1^{\,0}+\sin(\theta)\sin(\phi)\vec{e}_2^{\,0}+\cos(\theta)\vec{e}_3^{\,0}\tag{6.7.319}$$

The derivative of $\overrightarrow{\mathrm{O}M}$ with respect to θ gives the vector $\vec{e}_2$:

$$\vec{e}_2=\partial_2\vec{M}=r\cos(\theta)\cos(\phi)\vec{e}_1^{\,0}+r\cos(\theta)\sin(\phi)\vec{e}_2^{\,0}-r\sin(\theta)\vec{e}_3^{\,0}\tag{6.7.320}$$

The derivative with respect to φ gives the vector $\vec{e}_3$:

$$\vec{e}_3=\partial_3\vec{M}=-r\sin(\theta)\sin(\phi)\vec{e}_1^{\,0}+r\sin(\theta)\cos(\phi)\vec{e}_2^{\,0}\tag{6.7.321}$$

These three vectors are orthogonal to each other as we can easily verify it by performing the dot products $\vec{e}_i\circ\vec{e}_j$. When this is the case, we say that the coordinates are "orthogonal curvilinear coordinates" (see section Vector Calculus page 1849).

We thus find the same result as in the section of Vector Calculus! These vectors, however, are not all normalized (they're norm is not equal to 1) since we have:

$$g_{11}=\vec{e}_1\circ\vec{e}_1=1\quad g_{22}=\vec{e}_2\circ\vec{e}_2=r^2\quad g_{33}=\vec{e}_3\circ\vec{e}_3=r^2\sin^2(\theta)\tag{6.7.322}$$

The natural basis in spherical coordinates is thus formed by vectors that are variable in direction and in modulus at each point of M. The quantities g_{ij} constitute an example of a metric tensor attached to each of the points M of the space $\mathcal{E}^3$.

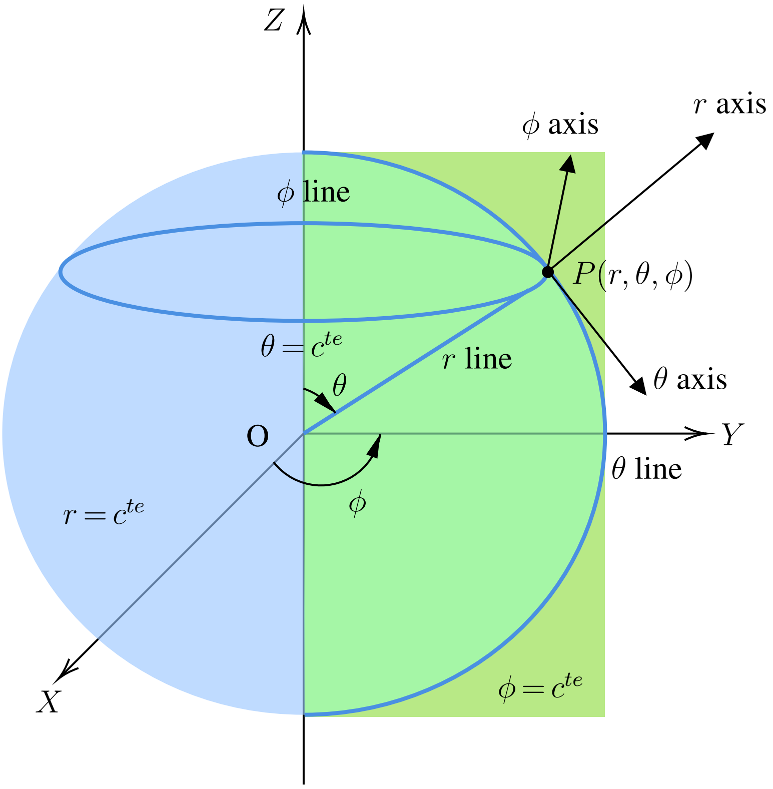

Figure 6.160: Coordinate surfaces, coordinate lines, and coordinate axes of spherical coordinates

The linear element of the surface is then given by (the details of the calculations can be found in the section of General Relativity):

$$\boxed{\mathrm{d}s^2 = \mathrm{d}r^2 + r^2\mathrm{d}\theta^2 + r^2\sin^2(\theta)\mathrm{d}\phi^2} \tag{6.7.323}$$

6.7.9.2 Natural basis in polar coordinates (curvilinear basis in polar coordinates)

Let us determine the natural basis of the vector space E^2 associated with the point space $\mathcal{E}^2$ of ordinary geometry, in polar coordinates. Let us write the expression of the vectors $\overrightarrow{\mathrm{O}M}$ in a fixed cartesian basis $(\vec{e}_i^{\,0})$ which is by definition (see the section Vector Calculus for more details):

$$\overrightarrow{OM} = x^i\vec{e}_i^{\,0} = r\cos(\phi)\vec{e}_1^{\,0} + r\sin(\phi)\vec{e}_2^{\,0} \tag{6.7.324}$$

The vectors of the natural basis are given by:

$$\vec{e}_k = \partial_k\vec{M} \Rightarrow \begin{cases} \vec{e}_1 = \partial_1\vec{M} = \partial_r\vec{M} \\ \vec{e}_2 = \partial_2\vec{M} = \partial_\phi\vec{M} \end{cases} \tag{6.7.325}$$

We have:

$$\vec{e}_1 = \partial_1\vec{M} = \cos(\phi)\vec{e}_1^{\,0} + \sin(\phi)\vec{e}_2^{\,0} \tag{6.7.326}$$

The derivative of $\overrightarrow{\mathrm{O}M}$ with respect to ϕ gives the vector $\vec{e}_2$:

$$\vec{e}_2 = \partial_2\vec{M} = -r\sin(\phi)\vec{e}_1^{\,0} + r\cos(\phi)\vec{e}_2^{\,0} \tag{6.7.327}$$

These two vectors are orthogonal to each other as we can easily verify by performing the dot products $\vec{e}_1 \circ \vec{e}_2$. We thus find the same result as in the section of Vector Calculus.

We then have:

$$g_{11} = \cos^2(\phi) + \sin^2(\phi) \quad g_{21} = g_{12} = 0 \quad g_{22} = r^2 \tag{6.7.328}$$

The linear element of the plane is then given by (the details of the calculations can be found in the section of General Relativity):

$$\boxed{\mathrm{d}s^2 = \mathrm{d}r^2 + r^2\mathrm{d}\phi^2} \tag{6.7.329}$$

6.7.9.3 Natural basis in cylindrical coordinates (cylindrical basis in polar coordinates)

Let us determine the natural basis of the vector space E^3 associated with the point space $\mathcal{E}^3$ of ordinary geometry, in cylindrical coordinates. Let us write the expression of the vectors $\overrightarrow{\mathrm{O}M}$ in a fixed cartesian basis $(\vec{e}_i^{\,0})$ which is by definition (see the section Vector Calculus for more details):

$$\overrightarrow{OM} = x^i\vec{e}_i^{\,0} = r\cos(\varphi)\vec{e}_1^{\,0} + r\sin(\varphi)\vec{e}_2^{\,0} + z\vec{e}_3^{\,0} \tag{6.7.330}$$

The vectors of the natural basis are given by:

$$\vec{e}_k=\partial_k\vec{M}\Rightarrow\begin{cases}\vec{e}_1=\partial_1\vec{M}=\partial_r\vec{M}\\ \vec{e}_2=\partial_2\vec{M}=\partial_\varphi\vec{M}\\ \vec{e}_3=\partial_3\vec{M}=\partial_z\vec{M}\end{cases}\qquad(6.7.331)$$

We have:

$$\vec{e}_1=\partial_1\vec{M}=\cos(\varphi)\vec{e}_1^{\,0}+\sin(\varphi)\vec{e}_2^{\,0}\qquad(6.7.332)$$

The derivative of $\overrightarrow{\mathrm{O}M}$ with respect to φ gives the vector $\vec{e}_2$:

$$\vec{e}_2=\partial_2\vec{M}=-r\sin(\phi)\vec{e}_1^{\,0}+r\cos(\phi)\vec{e}_2^{\,0}\qquad(6.7.333)$$

and finally:

$$\vec{e}_3=\partial_3\vec{M}=\vec{e}_3^{\,0}\qquad(6.7.334)$$

These three vectors are orthogonal to each other as we can easily verify by performing the dot products $\vec{e}_i\circ\vec{e}_j$. We thus find the same result as in the section of Vector Calculus.

We have:

$$g_{11}=1\quad g_{22}=r^2\quad g_{33}=1\qquad(6.7.335)$$

The linear element of the surface is then given by (the details of the calculations can be found in the section of General Relativity):

$$\boxed{\mathrm{d}s^2=\mathrm{d}r^2+r^2\mathrm{d}\phi^2+\mathrm{d}z^2}\qquad(6.7.336)$$

Notice now that:

$$(\mathrm{d}s)^2=g_{\mu\nu}\mathrm{d}x^\mu\mathrm{d}x^\nu\qquad(6.7.337)$$

expresses something about the intrinsic metrical relations of the space, but it does so in terms of a specific coordinate system. If we considered the metrical relations at the same point in terms of a different system of coordinates (such as changing from Cartesian to polar coordinates), the coefficients $g_{\mu\nu}$ would be different. Fortunately there is a simple way of converting the $g_{\mu\nu}$ from one system of coordinates to another, based on the fact that they describe a purely localistic relation among differential quantities. Suppose we are given the metrical coefficients $g_{\mu\nu}$ for the coordinates x^α, and we are also given another system of coordinates y^α that are defined in terms of the x^α by some arbitrary continuous functions:

$$\begin{matrix}y^0=f_0(x^0,x^1,x^2,x^3) & y^1=f_1(x^0,x^1,x^2,x^3)\\ y^2=f_2(x^0,x^1,x^2,x^3) & y^3=f_3(x^0,x^1,x^2,x^3)\end{matrix}\qquad(6.7.338)$$

Assuming the Jacobian of this transformation isn't zero, we know that it's invertible, and so we can just as well express the original coordinates as continuous functions (at this point) of the new coordinates:

$$\begin{matrix}x^0=F_0(y^0,y^1,y^2,y^3) & x^1=F_1(y^0,y^1,y^2,y^3)\\ x^2=F_2(y^0,y^1,y^2,y^3) & x^3=F_3(y^0,y^1,y^2,y^3)\end{matrix}\qquad(6.7.339)$$

Now we can evaluate the total derivatives of the original coordinates in terms of the new coordinates. For example, $\mathrm{d}x^0$ can be written as:

$$\mathrm{d}x^0=\frac{\partial x^0}{\partial y^0}\mathrm{d}y^0+\frac{\partial x^0}{\partial y^1}\mathrm{d}y^1+\frac{\partial x^0}{\partial y^2}\mathrm{d}y^2+\frac{\partial x^0}{\partial y^3}\mathrm{d}y^3 \tag{6.7.340}$$

and similarly for the $\mathrm{d}x^1, \mathrm{d}x^2$, and $\mathrm{d}x^3$. The product of any two of these differentials, $\mathrm{d}x^\mu$ and $\mathrm{d}x^\nu$, is of the form:

$$\mathrm{d}x^\mu \mathrm{d}x^\nu=\frac{\partial x^\mu}{\partial y^\alpha}\frac{\partial x^\nu}{\partial y^\beta}\mathrm{d}y^\alpha \mathrm{d}y^\beta \tag{6.7.341}$$

(remembering the summation convention giving 16 components). Substituting these expressions for the products of x differentials in the metric formula:

$$(\mathrm{d}s)^2=g_{\mu\nu}\mathrm{d}x^\mu \mathrm{d}x^\nu \tag{6.7.342}$$

gives:

$$(\mathrm{d}s)^2=g_{\mu\nu}\frac{\partial x^\mu}{\partial y^\alpha}\frac{\partial x^\nu}{\partial y^\beta}\mathrm{d}y^\alpha \mathrm{d}y^\beta \tag{6.7.343}$$

The first three factors on the right hand side obviously represent the coefficient of $\mathrm{d}y^\alpha \mathrm{d}y^\beta$ in the metric formula with respect to the y coordinates, so we've shown that the array of metric coefficients transforms from the x to the y coordinate system according to the relation:

$$\boxed{\left(g_{\alpha\beta}\right)_y=\frac{\partial x^\mu}{\partial y^\alpha}\frac{\partial x^\nu}{\partial y^\beta}\left(g_{\mu\nu}\right)_x} \tag{6.7.344}$$

Also often denoted:

$$g_{\alpha\beta}^{(y)}=\frac{\partial x^\mu}{\partial y^\alpha}\frac{\partial x^\nu}{\partial y^\beta}g_{\mu\nu}^{(x)} \tag{6.7.345}$$

and more rarely (sadly) denoted:

$$\boxed{\left(g_{\alpha\beta}\right)_y=\Lambda_\alpha^\mu\Lambda_\beta^\nu\left(g_{\mu\nu}\right)_x} \tag{6.7.346}$$

Notice that each component of the new metric array is a linear combination of the old metric components, and the coefficients are the partials of the old coordinates with respect to the new. Arrays that transform to each other in the way:

$$A_{\alpha\beta}=\frac{\partial x^\mu}{\partial y^\alpha}\frac{\partial x^\nu}{\partial y^\beta}A_{\mu\nu} \tag{6.7.347}$$

are named "(second order) covariant[33] tensors".

When we speak of an array being transformed from one system of coordinates to another, it's clear that the array must have a definite meaning independent of the system of coordinates. We could, for example, have an array of scalar quantities, whose values are the same at a given point, regardless of the coordinate system. However, the components of the array might still be required to change for different systems.

---

[33] Keep in mind that when a tensor expressed in terms of Cartesian coordinates, there is no distinction between covariant and contravariant components

Now we define arrays that transform to each other in the way:

$$A^{\mu\nu}=\frac{\partial x^{\mu}}{\partial y^{\alpha}}\frac{\partial x^{\nu}}{\partial y^{\beta}}A_{\alpha\beta} \tag{6.7.348}$$

as "(second order) contravariant tensors".

We will need this important result for our study of the Stress-Energy tensor in the section of General Relativity.

Now the reader must keep in mind that in General Relativity, we don't equip space-time (for a naive and technical definition of "space-time" see the section of Special Relativity at page 5708) itself with a vector space structure, which means that the "four-position" is not a four-vector! As a result, the object x_{μ} whose components are given by $x_{\mu}=g_{\mu\nu}x^{\nu}$ as proved earlier is not a covector! One can show this by its transformation properties.

If we change the coordinate systems from x to y, then:

$$\begin{gathered}g_{\mu\nu}^{(x)}\rightarrow g_{\mu\nu}^{(y)}=\frac{\partial x^{\alpha}}{\partial y^{\mu}}\frac{\partial x^{\beta}}{\partial y^{\nu}}g_{\alpha\beta}^{(x)}\\ x^{\nu}\rightarrow y^{\nu}\end{gathered} \tag{6.7.349}$$

and so:

$$x_{\mu}=g_{\mu\nu}^{(x)}x^{\nu}\rightarrow g_{\mu\nu}^{(y)}y^{\nu}=\frac{\partial x^{\alpha}}{\partial y^{\mu}}\frac{\partial x^{\beta}}{\partial y^{\nu}}g_{\alpha\beta}^{(x)}y^{\nu}=\frac{\partial x^{\alpha}}{\partial y^{\mu}}g_{\alpha\beta}^{(x)}\left(\frac{\partial x^{\beta}}{\partial y^{\nu}}y^{\nu}\right) \tag{6.7.350}$$

If this object was a covector, it would transform as proven earlier using the covariant transformation:

$$x_{\mu}\rightarrow y_{\mu}=\frac{\partial x^{\alpha}}{\partial y^{\mu}}x_{\alpha}=\frac{\partial x^{\alpha}}{\partial y^{\mu}}g_{\alpha\beta}^{(x)}x^{\beta} \tag{6.7.351}$$

Comparing this to what we found above, this is only true if:

$$\frac{\partial x^{\beta}}{\partial y^{\nu}}y^{\nu}=x^{\beta} \tag{6.7.352}$$

i.e. if the coordinate transformation is linear. Since coordinate transformations are, in general, not linear, then this equality does not hold, and x_{ν} are not the components of a covector.

Finally another obvious identity that you can also sometimes found in some rare textbooks is (I never see a practical application of that latter):

$$\frac{\partial x^{\lambda}}{\partial x^{\mu}}\frac{\partial x^{\mu}}{\partial x^{\nu}}=\delta_{\mu}^{\lambda}\delta_{\nu}^{\mu}=\delta_{\nu}^{\lambda}=g_{\nu}^{\lambda} \tag{6.7.353}$$

6.7.10 Christoffel symbols

The study of tensor fields constitutes, for the physicist, the essential element of the tensorial analysis. The generic tensor $\vec{U}$ of this field is a function of the point M and we will denote it simply by:

$$\vec{U}(M) \tag{6.7.354}$$

If the tensor $\vec{U}$ is a function only of M, the field considered is named a "fixed field". If $\vec{U}$ is moreover a function of one or more equation parameters other than the coordinates of M, then we say that this is a "variable field" and we note it:

$$\vec{U}(M,\alpha) \tag{6.7.355}$$

The different algebraic operations on the tensors $\vec{U}(M)$ associated with a same point M do not generates any particular difficulty. The derivative of $\vec{U}(M)$ with respect to a parameter α leads to the use of the classical results relating to the derivation of the vectors.

However, a difficulty appears when we try to calculate the derivative of a tensor $\vec{U}(M)$ with respect to the curvilinear coordinates. Indeed, the components of the tensor are defined at each point M with respect to a natural coordinate system which varies from one point to another.

Consequently, the calculation of the elementary variation, named "elementary transport":

$$\vec{U}(M')-\vec{U}(M) \tag{6.7.356}$$

When we pass from a point M to an infinitely neighbouring point M' this can be done in physics only if we use to the same basis. In order to compare the tensors $\vec{U}(M')$ and $\vec{U}(M)$ each other, we are led to study how a natural coordinate system for a given coordinate system varies when we pass from a point M to an infinitely close point M'.

For a system of curvilinear coordinates u^i given a punctual space $\mathcal{E}^n$, a fundamental problem of tensor analysis consists in determining, with respect to the natural reference point $(M,\vec{e}_k)$ at the point M, the natural reference point $(M',\vec{e}_k')$ at the infinitely close point M'. We then say that we are looking for an "affine connection".

On the one hand, the point M' will be perfectly defined with respect to M if we determine the vector $\mathrm{d}\vec{M}$ such as $\overrightarrow{MM'}=\mathrm{d}\vec{M}$. For curvilinear coordinates u^k, the decomposition of an elementary vector $\mathrm{d}\vec{M}$ is given by the relation that we have previously proved:

$$\mathrm{d}\vec{M}=\partial_k\vec{M}\mathrm{d}u^k=\vec{e}_k\mathrm{d}u^k \tag{6.7.357}$$

the quantities $\mathrm{d}u^k$ being for recall the contravariant components of the vector $\mathrm{d}\vec{M}$ on the natural basis $(\vec{e}_k)$.

And now to make things physically comparable, we must guarantee that vectors of the both basis are also parallel! So the idea is that the derivative we are looking for allows one to transport vectors of a manifold (surface) along curves so that they stay parallel with respect to the connection (derivative). Such an idea is named in physics "parallel transport".

Therefore, the idea is to determine the vector $\vec{e}'_k$ with elementary variations $\mathrm{d}\vec{e}_k$ of the vector $\vec{e}_k$ relatively to the natural reference frame $(M,\vec{e}_k)$, when we go from M to M'. We then have:

$$\mathrm{d}\vec{e}'_k=\vec{e}_k+\mathrm{d}\vec{e}_k \tag{6.7.358}$$

The computation of the vectors $\mathrm{d}\vec{e}_k$ then remains the main problem to solve. We will first consider an example of this type of calculation in spherical coordinates for pedagogical purposes as it can help to understand what will follows.

For this, let us return the expression of the vectors $\vec{e}_k$ of the natural base in spherical coordinates, that is:

$$\begin{aligned}\vec{e}_1&=\partial_1\vec{M}=\sin(\theta)\cos(\phi)\vec{\imath}+\sin(\theta)\sin(\phi)\vec{\jmath}+\cos(\theta)\vec{k}\\ \vec{e}_2&=\partial_2\vec{M}=r\cos(\theta)\cos(\phi)\vec{\imath}+r\cos(\theta)\sin(\phi)\vec{\jmath}-r\sin(\theta)\vec{k}\\ \vec{e}_3&=\partial_3\vec{M}=-r\sin(\theta)\sin(\phi)\vec{\imath}+r\sin(\theta)\cos(\phi)\vec{\jmath}\end{aligned} \tag{6.7.359}$$

Since the basis vectors $\vec{\imath},\vec{\jmath},\vec{k}$ of the fixed Cartesian reference being constant in modulus and in direction, the differential of the vector $\vec{e}_1$ is written:

$$\mathrm{d}\vec{e}_1=(\cos(\theta)\cos(\phi)\vec{\imath}+\cos(\theta)\sin(\phi)\vec{\jmath}-\sin(\theta)\vec{k})\mathrm{d}\theta+(-\sin(\theta)\sin(\phi)+\sin(\theta)\cos(\phi)\vec{\jmath})\mathrm{d}\phi \tag{6.7.360}$$

We notice that the terms in parentheses represent respectively the vectors $\vec{e}_2/r$ and $\vec{e}_3/r$, hence:

$$\mathrm{d}\vec{e}_1=\left(\frac{\mathrm{d}\theta}{r}\right)\vec{e}_2+\left(\frac{\mathrm{d}\phi}{r}\right)\vec{e}_3 \tag{6.7.361}$$

We also compute, by differentiating the vector $\vec{e}_2$:

$$\begin{aligned}\mathrm{d}\vec{e}_2=&\,\mathrm{d}r\cos(\theta)\cos(\phi)\vec{\imath}+\mathrm{d}r\cos(\theta)\sin(\phi)\vec{\jmath}-\mathrm{d}r\sin(\theta)\vec{k}\\ &-r\sin(\theta)\mathrm{d}\theta\cos(\phi)\vec{\imath}-r\sin(\theta)\mathrm{d}\theta\sin(\phi)\vec{\jmath}-r\cos(\theta)\mathrm{d}\theta\vec{k}\\ &-r\cos(\theta)\sin(\phi)\mathrm{d}\phi\vec{\imath}+r\cos(\theta)\cos(\phi)\mathrm{d}\phi\vec{\jmath}\\ &=(\cos(\theta)\cos(\phi)\vec{\imath}+\cos(\theta)\sin(\phi)\vec{\jmath}-\sin(\theta)\vec{k})\mathrm{d}r+(-r\sin(\theta)\cos(\phi)\vec{\imath}-r\sin(\theta)\sin(\phi)\vec{\jmath}-r\cos(\theta)\vec{k})\mathrm{d}\theta\\ &+(-r\cos(\theta)\sin(\phi)\vec{\imath}+r\cos(\theta)\cos(\phi)\vec{\jmath})\mathrm{d}\phi\\ &=\frac{\vec{e}_2}{r}\mathrm{d}r-r\vec{e}_1\mathrm{d}\theta+(-r\cos(\theta)\sin(\phi)\vec{\imath}+r\cos(\theta)\cos(\phi)\vec{\jmath})\mathrm{d}\phi\end{aligned} \tag{6.7.362}$$

with:

$$\cot(\theta)=\frac{\cos(\theta)}{\sin(\theta)} \tag{6.7.363}$$

we have:

$$\vec{e}_3\cot(\theta)=\vec{e}_3\frac{\cos(\theta)}{\sin(\theta)}=-r\cos(\theta)\sin(\phi)\vec{\imath}+r\cos(\theta)\cos(\phi)\vec{\jmath} \tag{6.7.364}$$

So finally:

$$\mathrm{d}\vec{e}_2=\frac{\vec{e}_2}{r}\mathrm{d}r-r\vec{e}_1\mathrm{d}\theta+\vec{e}_3\cot(\theta)\mathrm{d}\phi \tag{6.7.365}$$

And:

$$\begin{aligned}\mathrm{d}\vec{e}_3=&-\mathrm{d}r\sin(\theta)\sin(\phi)\vec{i}+\mathrm{d}r\sin(\theta)\cos(\phi)\vec{j}\\&-r\cos(\theta)\mathrm{d}\theta\sin(\phi)\vec{i}+r\cos(\theta)\mathrm{d}\theta\cos(\phi)\vec{j}\\&-r\sin(\theta)\cos(\phi)\mathrm{d}\phi\vec{i}-r\sin(\theta)\sin(\phi)\mathrm{d}\phi\vec{j}\end{aligned} \quad (6.7.366)$$

After a few elementary and very tricky algebraic operations (...), we get:

$$\mathrm{d}\vec{e}_3=(-r\sin^2(\theta)\mathrm{d}\phi)\vec{e}_1+(-\sin(\theta)\cos(\theta)\mathrm{d}\phi)\vec{e}_2+\left(\frac{\mathrm{d}r}{r}+\cot(\theta)\mathrm{d}\theta\right)\vec{e}_3 \quad (6.7.367)$$

The differentials $\mathrm{d}\vec{e}_k$ are thus decomposed on the natural basis $(\vec{e}_k)$. If we denote by ω_i^k the contravariant components of the vector $\mathrm{d}\vec{e}_1$, that latter is written:

$$\boxed{\mathrm{d}\vec{e}_i=\omega_i^k\vec{e}_k} \quad (6.7.368)$$

The components ω_i^k of the vector $\mathrm{d}\vec{e}_i$ are differential forms (linear combinations of differentials). We have, for example:

$$\omega_1^2=\frac{\mathrm{d}\theta}{r} \qquad \omega_3^3=\frac{\mathrm{d}r}{r}+\cot(\theta)\mathrm{d}\theta \quad (6.7.369)$$

If we denote in a general way by u^i the spherical coordinates, we have:

$$u^1=r \qquad u^2=\theta \qquad u^3=\phi \quad (6.7.370)$$

The coordinate differentials are then denoted:

$$\mathrm{d}u^1=\mathrm{d}r \qquad \mathrm{d}u^2=\mathrm{d}\theta \qquad \mathrm{d}u^3=\mathrm{d}\phi \quad (6.7.371)$$

and the components ω_i^j are then written in a general way:

$$\boxed{\omega_i^j=\Gamma_{ki}^j\mathrm{d}u^k} \quad (6.7.372)$$

Where the quantities Γ_{ki}^j are functions of r,θ,ϕ that will be explicitly obtained by identifying each component ω_i^j. For example, the component ω_3^3 is written with the notation of the previous relation:

$$\omega_3^3=\frac{\mathrm{d}r}{r}+\cot(\theta)\mathrm{d}\theta=\Gamma_{13}^3\mathrm{d}u^1+\Gamma_{23}^3\mathrm{d}u^2+\Gamma_{33}^3\mathrm{d}u^3 \quad (6.7.373)$$

Identifying the coefficients of the differentials, it comes:

$$\Gamma_{13}^3=\frac{1}{r} \qquad \Gamma_{23}^3=\cot(\theta) \qquad \Gamma_{33}^3=0 \quad (6.7.374)$$

By doing the same with the 9 components ω_i^j, we get the 27 (...) terms for which the detailed calculations for the $3\cdot 9=27$ are given much further below in the text. For any curvilinear coordinate system, these quantities Γ_{ki}^j are named "Christoffel symbols of the second kind" or "Euclidean functions of affine connection".

Thus, for a punctual space $\mathcal{E}^3$ and a system of any curvilinear coordinates u^j, the differential $\vec{e}_i=\omega_i^k\vec{e}_k$ of the vectors $\vec{e}_i$ of the natural basis is written on this basis:

$$\mathrm{d}\vec{e}_k=\omega_i^k\vec{e}_k=\Gamma_{ji}^k\mathrm{d}u^j\vec{e}_k \quad (6.7.375)$$

where Γ_{ji}^k in this context is often named "Levi-Civita connection".

Remark

Therefore this also means that given a vector $\vec{v}$ such that:

$$\vec{v}=v^i\vec{e}_i \tag{6.7.376}$$

Thus:

$$\mathrm{d}\vec{v}=\mathrm{d}v^k\vec{e}_k+v^k\mathrm{d}\vec{e}_k \tag{6.7.377}$$

But as:

$$\mathrm{d}\vec{e}_k=\Gamma_{ji}^k\mathrm{d}u^j\vec{e}_k \tag{6.7.378}$$

we have then:

$$\boxed{\mathrm{d}\vec{v}=\left(\mathrm{d}v^k+\Gamma_{ji}^k\mathrm{d}u^j\right)\vec{e}_k} \tag{6.7.379}$$

We have just seen, on the example of the spherical coordinates, that a direct calculation makes it possible, by identification, to obtain explicitly the quantities Γ_{ki}^j. We shall see that we can also obtain the expression of these quantities as a function of the components of g_{ij}.

The calculation of the quantities Γ_{ki}^j as a function of the g_{ij} will lead us to introduce other Christoffel symbols. For this, let us write the covariant components, denoted ω_{ji}, of the differentials $\mathrm{d}\vec{e}_i$, thus (it's kind a definition):

$$\omega_{ji}=\vec{e}_j\circ d\vec{e}_i \tag{6.7.380}$$

✍**Example:**

With our example above:

$$\vec{e}_3=\partial_3\vec{M}=-r\sin(\theta)\sin(\phi)\vec{i}+r\sin(\theta)\cos(\phi)\vec{j} \tag{6.7.381}$$

and:

$$\mathrm{d}\vec{e}_3=(-r\sin^2(\theta)\mathrm{d}\phi)\vec{e}_1+(-\sin(\theta)\cos(\theta)\mathrm{d}\phi)\vec{e}_2+\left(\frac{\mathrm{d}r}{r}+\cot(\theta)\mathrm{d}\theta\right)\vec{e}_3 \tag{6.7.382}$$

We get (most dot products are orthogonal vectors, therefore they vanish):

$$\begin{aligned}\omega_{33}=\vec{e}_3\circ d\vec{e}_3&=\vec{e}_3\circ\left((-r\sin^2(\theta)\mathrm{d}\phi)\vec{e}_1+(-\sin(\theta)\cos(\theta)\mathrm{d}\phi)\vec{e}_2+\left(\frac{\mathrm{d}r}{r}+\cot(\theta)\mathrm{d}\theta\right)\vec{e}_3\right)\\&=\left(\frac{\mathrm{d}r}{r}+\cot(\theta)\mathrm{d}\theta\right)\vec{e}_3\circ\vec{e}_3=\left(\frac{\mathrm{d}r}{r}+\cot(\theta)\mathrm{d}\theta\right)r^2\sin^2(\theta)=r\sin^2(\theta)\mathrm{d}r+r^2\cot(\theta)\mathrm{d}\theta\end{aligned} \tag{6.7.383}$$

The covariant components are also a linear combinations of the differentials $\mathrm{d}u^k$ that we can write in the form:

$$\omega_{ji}=\Gamma_{kji}du^k \tag{6.7.384}$$

The quantities Γ_{kji} are named the "Christoffel symbols of the first kind".

We see quite clearly by going through the definitions and examples of the Christoffel symbols above again that:

1. For the Christoffel symbols of the second kind, they are symmetrical with respect to their lower indices and therefore if the metric is symmetric, we have:

$$\Gamma_{ji}^{k}=\Gamma_{ij}^{k} \tag{6.7.385}$$

2. For the Christoffel symbols of the first kind, they are also symmetrical with respect to their extremal indices and therefore if the metric is symmetric, we have:

$$\Gamma_{kij}=\Gamma_{jik} \tag{6.7.386}$$

Indeed (following the request of a reader), since we have:

$$\mathrm{d}\vec{e}_k=\omega_i^k\vec{e}_k=\Gamma_{ji}^k\mathrm{d}u^j\vec{e}_k \tag{6.7.387}$$

it then comes:

$$\frac{\partial\vec{e}_k}{\partial u^j}=\vec{e}_k\Gamma_{ji}^k \tag{6.7.388}$$

and by swapping the indices i and j:

$$\frac{\partial\vec{e}_k}{\partial u^j}=\vec{e}_k\Gamma_{ij}^k \tag{6.7.389}$$

The term-to-term identification of the development on a concrete case of the last two relations will give (necessarily) the equality:

$$\Gamma_{ij}^k=\Gamma_{ji}^k \tag{6.7.390}$$

that we wanted to prove.

Since the covariant components are related to the contravariant components by the relations (contraction of indices):

$$\omega_{ji}=g_{jl}\omega_i^l=g_{jl}\Gamma_{ki}\mathrm{d}u^k \tag{6.7.391}$$

We get the expression linking the Christoffel symbols of each kind:

$$\boxed{\Gamma_{kji}=g_{jl}\Gamma_{ki}^l} \tag{6.7.392}$$

Conversely:

$$\boxed{\Gamma_{ki}^j=g^{jl}\Gamma_{kli}} \tag{6.7.393}$$

Remark

Various notations are used to represent the Christoffel symbols. The most common are:

- Christoffel symbol of the first kind:

$$\Gamma_{kji}=[ki,j] \tag{6.7.394}$$

- Christoffel symbol of the second kind:

$$\Gamma^{j}_{ki}=[k^j\, i] \tag{6.7.395}$$

Let us consider now a punctual space $\mathcal{E}^n$ and given a linear element $\mathrm{d}s^2$ of this space:

$$\mathrm{d}s^2=g_{ij}\mathrm{d}u^i\mathrm{d}u^j \tag{6.7.396}$$

Starting from:

$$g_{ij}=\vec{e}_i\circ\vec{e}_j \tag{6.7.397}$$

we get by differentiation:

$$\mathrm{d}g_{ij}=\vec{e}_i\circ\mathrm{d}\vec{e}_j+\vec{e}_j\circ\mathrm{d}\vec{e}_i \tag{6.7.398}$$

By injecting in it the expression of the differential $\mathrm{d}\vec{e}_j=\omega^l_j\vec{e}_l$ this gives us:

$$\mathrm{d}g_{ij}=(\vec{e}_i\circ\vec{e}_l)\omega^l_j+(\vec{e}_j\circ\vec{e}_l)\omega^l_i=g_{il}\omega^l_j+g_{jl}\omega^l_i \tag{6.7.399}$$

where the term represents ω^l_j represents the mixed component of the vector $\mathrm{d}\vec{e}_j$. We can make this component covariant by multiplying it by the metric tensor g_{il} so as to form an ω_{ij} quantity which can in turn be expressed by means of the Christoffel symbols as follows as we already know:

$$\omega_{ij}=g_{il}\omega^l_j=g_{il}\Gamma^l_{kj}\mathrm{d}u^k \tag{6.7.400}$$

Substituting the relation $\Gamma_{kji}=g_{jl}\Gamma^l_{ki}$ in the preceding expression (the indices used in this relation are not those of the expression in question, but mutatis mutandis it is equivalent), we then get:

$$\omega_{ij}=\Gamma_{kij}\mathrm{d}u^k \tag{6.7.401}$$

The differential $\mathrm{d}g_{ij}$ is then written:

$$\boxed{\mathrm{d}g_{ij}=\omega_{ij}+\omega_{ji}=\left(\Gamma_{kij}+\Gamma_{kji}\right)\mathrm{d}u^k} \tag{6.7.402}$$

On the other hand, the differential of the function g_{ij} is then written:

$$\boxed{\mathrm{d}g_{ij}=\frac{\partial g_{ij}}{\partial u^k}\mathrm{d}u^k=\partial_k g_{ij}\mathrm{d}u^k} \tag{6.7.403}$$

hence by identifying the coefficients of the differentials $\mathrm{d}u^k$ in these two last expressions (much further below in this section there is a detailed example of all the relations which will follow with several coordinate systems):

$$\Gamma_{kij}+\Gamma_{kji}=\partial_k g_{ij} \tag{6.7.404}$$

Relation that the reader can (if he doubt about its veracity) check with the detailed practical examples which are given much further below.

As we have (in the case of a symmetric metric):

$$\Gamma_{kij}=\Gamma_{kji} \tag{6.7.405}$$

where it is strongly recommended to the reader to remember that the permutation of the indices respecting this last relation generally only works on the extreme indices!

We can therefore write the prior-previous relation as:

$$\Gamma_{jik}+\Gamma_{kji}=\partial_k g_{ij} \tag{6.7.406}$$

and by performing a circular permutation on the indices (hence it is not a permutation of the extreme indices!), we get:

$$\Gamma_{kji}+\Gamma_{ikj}=\partial_i g_{jk}\Gamma_{ikj}+\Gamma_{jik}=\partial_j g_{kj} \tag{6.7.407}$$

By making the sum:

$$\begin{array}{cr} & \Gamma_{jik}+\Gamma_{kji}=\partial_k g_{ij}\\ & \Gamma_{kji}+\Gamma_{ikj}=\partial_i g_{jk}\\ \hline + & \Gamma_{jik}+\Gamma_{kji}+\Gamma_{kji}+\Gamma_{ikj}=\partial_k g_{ij}+\partial_i g_{jk} \end{array} \tag{6.7.408}$$

and by subtracting:

$$\begin{array}{cr} & \Gamma_{jik}+\Gamma_{kji}+\Gamma_{kji}+\Gamma_{ikj}=\partial_k g_{ij}+\partial_i g_{jk}\\ & \Gamma_{ikj}+\Gamma_{jik}=\partial_j g_{kj}\\ \hline - & \Gamma_{jik}+\Gamma_{kji}+\Gamma_{kji}+\Gamma_{ikj}-\Gamma_{ikj}-\Gamma_{jik}=\partial_k g_{ij}+\partial_i g_{jk}-\partial_j g_{ki} \end{array} \tag{6.7.409}$$

Simplifying it comes:

$$2\Gamma_{kji}=\partial_k g_{ij}+\partial_i g_{jk}-\partial_j g_{ki} \tag{6.7.410}$$

therefore:

$$\boxed{\Gamma_{kji}=\frac{1}{2}(\partial_k g_{ij}+\partial_i g_{jk}-\partial_j g_{ki})} \tag{6.7.411}$$

It is the expression of the Christoffel symbols of the first kind as a function of the partial derivatives of the components g_{ij} of the fundamental tensor named "first Christoffel identity". We thus understand why in a locally inertial frame (of the Minkowski type) the Christoffel symbols are all zero (given that the metric is constant).

We get those of the second kind from the following relation (by definition) named "fundamental theorem of Riemannian geometry" or "Levi-Civita connection" or "first Christoffel identity":

$$\boxed{\Gamma_{kj}^{i}=g^{il}\Gamma_{klj}=\frac{1}{2}g^{il}(\partial_k g_{lj}+\partial_j g_{kl}-\partial_l g_{kj})} \tag{6.7.412}$$

The last two expressions listed above allow the actual calculation of the Christoffel symbols for a given metric (hence an enormous gain in calculations). When the quantities g_{ij} are given a priori, we can study the properties of the punctual space defined by the data of this metric, which is the case of the Riemann spaces we will see later.

For our study of Cosmology we will need to calculate:

$$\Gamma_{ki}^{i}=g^{im}\Gamma_{mki}=\frac{1}{2}g^{im}(\partial_i g_{mk}+\partial_k g_{mi}-\partial_m g_{ki}) \tag{6.7.413}$$

For this purpose, notice that:

$$\begin{aligned} g^{im}\partial_i g_{mk} &= g^{im}\partial_i g_{km} && \text{(symmetry of } g\text{)}\\ &= g^{mi}\partial_m g_{ki} && \text{(relabeling dummy indices)}\\ &= g^{im}\partial_m g_{ki} && \text{(symmetry of } g\text{)} \end{aligned}$$

Therefore:

$$\Gamma_{ki}^{i}=\frac{1}{2}g^{im}(\partial_i g_{mk}+\partial_k g_{mi}-\partial_m g_{ki})=\frac{1}{2}g^{im}\partial_k g_{mi} \tag{6.7.414}$$

✍**Example:**

We propose to calculate the Christoffel symbols of the second kind Γ_{kj}^{i} corresponding to the polar coordinate system in the plane (it will be sufficiently long...) that we will write this time (at the opposite of the section of Vector Calculus) in index notation:

$$\begin{array}{ccc} x^1=y^1\cos\left(y^2\right) & & y^1=\sqrt{\left(x^1\right)^2+\left(x^2\right)^2} \\ & \text{with} & \\ x^2=y^1\sin\left(y^2\right) & & y^2=\arctan\left(\dfrac{x^2}{x^1}\right) \end{array} \tag{6.7.415}$$

We will calculate the Christoffel symbols of the second kind from our last relation:

$$\Gamma_{kj}^{i}=g^{il}\Gamma_{klj}=\frac{1}{2}g^{il}(\partial_j g_{kl}+\partial_k g_{lj}-\partial_l g_{kj}) \tag{6.7.416}$$

Let us determine the components of the metric. By the way, they are the same as those we had calculated for the cylindrical coordinates above with the obvious difference that g_{33} does not exist. Therefore, we have:

$$g_{11}=1 \qquad g_{12}=g_{21}=0 \qquad g_{22}=\left(y^1\right)^2 \tag{6.7.417}$$

Let us then calculate the g_{ji}. In this example it is rather trivial, it is enough to apply the relation demonstrated at the beginning of this section:

$$g_{ik}g^{kj}=\delta_i^j \tag{6.7.418}$$

Or by dealing as with standard matrices (see section Linear Algebra page 1981):

$$g^{ji}=(g_{ik})^{-1}=\frac{1}{g_{11}g_{22}-g_{12}g_{21}}\begin{bmatrix} g_{22} & -g_{12}\\ -g_{21} & g_{11}\end{bmatrix} \tag{6.7.419}$$

We then have immediately:

$$g^{11}=1 \qquad g^{12}=g^{21}=0 \qquad g^{22}=\frac{1}{\left(y^1\right)^2} \tag{6.7.420}$$

Now let us develop the Christoffel symbols writing for these coordinates:

$$\begin{aligned}
\Gamma_{11}^1&=\frac{1}{2}g^{1l}\left(\frac{\partial g_{1l}}{\partial y^1}+\frac{\partial g_{l1}}{\partial y^1}-\frac{\partial g_{11}}{\partial y^l}\right) \qquad l=1,2\\
&=\frac{1}{2}g^{11}\left(\frac{\partial g_{11}}{\partial y^1}+\frac{\partial g_{11}}{\partial y^1}-\frac{\partial g_{11}}{\partial y^1}\right)+\frac{1}{2}g^{12}\left(\frac{\partial g_{12}}{\partial y^1}+\frac{\partial g_{21}}{\partial y^1}-\frac{\partial g_{11}}{\partial y^2}\right)=0\\
\Gamma_{11}^2&=\frac{1}{2}g^{2l}\left(\frac{\partial g_{1l}}{\partial y^1}+\frac{\partial g_{l1}}{\partial y^1}-\frac{\partial g_{11}}{\partial y^l}\right) \qquad l=1,2\\
&=\frac{1}{2}g^{21}\left(\frac{\partial g_{11}}{\partial y^1}+\frac{\partial g_{11}}{\partial y^1}-\frac{\partial g_{11}}{\partial y^1}\right)+\frac{1}{2}g^{22}\left(\frac{\partial g_{12}}{\partial y^1}+\frac{\partial g_{21}}{\partial y^1}-\frac{\partial g_{11}}{\partial y^2}\right)=0\\
\Gamma_{12}^1&=\frac{1}{2}g^{1l}\left(\frac{\partial g_{1l}}{\partial y^2}+\frac{\partial g_{l2}}{\partial y^1}-\frac{\partial g_{21}}{\partial y^l}\right) \qquad l=1,2\\
&=\frac{1}{2}g^{11}\left(\frac{\partial g_{11}}{\partial y^2}+\frac{\partial g_{12}}{\partial y^1}-\frac{\partial g_{21}}{\partial y^1}\right)+\frac{1}{2}g^{12}\left(\frac{\partial g_{12}}{\partial y^2}+\frac{\partial g_{22}}{\partial y^1}-\frac{\partial g_{21}}{\partial y^2}\right)=0\\
\Gamma_{12}^2&=\frac{1}{2}g^{2l}\left(\frac{\partial g_{1l}}{\partial y^2}+\frac{\partial g_{l2}}{\partial y^1}-\frac{\partial g_{21}}{\partial y^l}\right) \qquad l=1,2\\
&=\frac{1}{2}g^{21}\left(\frac{\partial g_{11}}{\partial y^2}+\frac{\partial g_{12}}{\partial y^1}-\frac{\partial g_{11}}{\partial y^1}\right)+\frac{1}{2}g^{22}\left(\frac{\partial g_{12}}{\partial y^2}+\frac{\partial g_{22}}{\partial y^1}-\frac{\partial g_{21}}{\partial y^2}\right)\\
&=\frac{1}{2}g^{22}\frac{\partial g_{22}}{\partial y^1}=\frac{1}{2}\frac{1}{\left(y^1\right)^2}2y^1=\frac{1}{y^1}
\end{aligned} \tag{6.7.421}$$

Hence due to the properties of symmetry:

$$\begin{aligned}
\Gamma_{21}^1&=\Gamma_{12}^1=0\\
\Gamma_{21}^2&=\Gamma_{12}^2=\frac{1}{y^1}
\end{aligned} \tag{6.7.422}$$

In the same way:

$$\begin{aligned}
\Gamma_{22}^1&=\frac{1}{2}g^{1l}\left(\frac{\partial g_{2l}}{\partial y^2}+\frac{\partial g_{l2}}{\partial y^2}-\frac{\partial g_{22}}{\partial y^l}\right) \qquad l=1,2\\
&=\frac{1}{2}g^{11}\left(\frac{\partial g_{21}}{\partial y^2}+\frac{\partial g_{12}}{\partial y^2}-\frac{\partial g_{22}}{\partial y^1}\right)+\frac{1}{2}g^{12}\left(\frac{\partial g_{22}}{\partial y^2}+\frac{\partial g_{22}}{\partial y^2}-\frac{\partial g_{22}}{\partial y^2}\right)\\
&=-\frac{1}{2}g^{11}\frac{\partial g_{22}}{\partial y^1}=-\frac{1}{2}\cdot 1\cdot 2y^1=-y^1\\
\Gamma_{22}^2&=\frac{1}{2}g^{2l}\left(\frac{\partial g_{2l}}{\partial y^2}+\frac{\partial g_{l2}}{\partial y^2}-\frac{\partial g_{22}}{\partial y^l}\right) \qquad l=1,2\\
&=\frac{1}{2}g^{21}\left(\frac{\partial g_{21}}{\partial y^2}+\frac{\partial g_{12}}{\partial y^2}-\frac{\partial g_{22}}{\partial y^1}\right)+\frac{1}{2}g^{22}\left(\frac{\partial g_{22}}{\partial y^2}+\frac{\partial g_{22}}{\partial y^2}-\frac{\partial g_{22}}{\partial y^2}\right)\\
&=\frac{1}{2}g^{22}\frac{\partial g_{22}}{\partial y^2}=0
\end{aligned} \tag{6.7.423}$$

To sum up:

$$\begin{array}{cccc} \Gamma_{11}^{1}=0 & \Gamma_{12}^{1}=0 & \Gamma_{21}^{1}=0 & \Gamma_{22}^{1}=-y^{1} \\ \Gamma_{11}^{2}=0 & \Gamma_{12}^{2}=\dfrac{1}{y^{1}} & \Gamma_{21}^{2}=\dfrac{1}{y^{1}} & \Gamma_{22}^{2}=0 \end{array} \tag{6.7.424}$$

6.7.11 Ricci Theorem

Before reading what follows ... We want to remind the reader that the writing of this section is not finished (as most chapters in the book)! Thus, we still have to illustrate the abstract notions that will follow with concrete practical examples but that are examples outside of the special case of General Relativity!

This being said, we have seen in the section of General Relativity that geodesics are the shortest distances between two points in any type of space. What will interest us now is to study the variations of a vector during such a displacement. Let us first recall that the geodesics equation for any curvilinear coordinate system y^i of the punctual space $\mathcal{E}^n$ (see section Principles page 3145) is given by (see section General Relativity page 5747):

$$\frac{\mathrm{d}^2y^i}{\mathrm{d}s^2}+\Gamma_{kj}^{i}\frac{\mathrm{d}y^i}{\mathrm{d}s}\frac{\mathrm{d}y^k}{\mathrm{d}s}=0 \tag{6.7.425}$$

Let us consider now a vector $\vec{v}$ of $\mathcal{E}^n$ of covariant components v_i and let us form the dot product of the vector $\vec{v}$ and $\vec{n}=\mathrm{d}y/\mathrm{d}s$ (the latter vector, denoted here abusively with the indices, gives the components tangent to the geodesic on which the first vector flows), we then have the following quantity:

$$\vec{v}\circ\vec{n}=v_i\frac{\mathrm{d}y^i}{\mathrm{d}s} \tag{6.7.426}$$

When moving along the geodesic from a point M to an infinitely near point M', the scalar undergoes the variation:

$$\mathrm{d}\left(v_i\frac{\mathrm{d}y^i}{\mathrm{d}s}\right)=\mathrm{d}v_k\frac{\mathrm{d}y^k}{\mathrm{d}s}+v_i\mathrm{d}\left(\frac{\mathrm{d}y^i}{\mathrm{d}s}\right) \tag{6.7.427}$$

and as:

$$\frac{\mathrm{d}\left(\dfrac{\mathrm{d}y^i}{\mathrm{d}s}\right)}{\mathrm{d}s}=\frac{\mathrm{d}^2y^i}{\mathrm{d}s^2}\Rightarrow\mathrm{d}\left(\frac{\mathrm{d}y^i}{\mathrm{d}s}\right)=\frac{\mathrm{d}^2y^i}{\mathrm{d}s^2}\mathrm{d}s \tag{6.7.428}$$

Hence:

$$\mathrm{d}\left(v_i\frac{\mathrm{d}y^i}{\mathrm{d}s}\right)=\mathrm{d}v_k\frac{\mathrm{d}y^k}{\mathrm{d}s}+v_i\frac{\mathrm{d}^2y^i}{\mathrm{d}s^2}ds \tag{6.7.429}$$

Let us replace in this last expression, on the one hand, the differential of $\mathrm{d}v_K$ by its exact total differential that we rewrite a bit:

$$\mathrm{d}v_k=\frac{\partial v_k}{\partial y_j}\mathrm{d}y^i=\partial_j v_k\frac{\mathrm{d}s}{\mathrm{d}s}dy^i=\partial_j v_k\frac{\mathrm{d}y^i}{\mathrm{d}s}\mathrm{d}s \qquad (6.7.430)$$

and on the other hand, the second derivative $\mathrm{d}^2y^i/\mathrm{d}s$ by its expression taken from the equation of geodesics. We are getting:

$$\mathrm{d}\left(v_i\frac{\mathrm{d}y^i}{\mathrm{d}s}\right)=\partial_j v_k\frac{\mathrm{d}y^i}{\mathrm{d}s}\frac{\mathrm{d}y^k}{\mathrm{d}s}\mathrm{d}s-v_i\Gamma_{kj}^i\frac{\mathrm{d}y^j}{\mathrm{d}s}\frac{\mathrm{d}y^k}{\mathrm{d}s}\mathrm{d}s=(\partial_i v_k-v_i\Gamma_{kj}^i)\frac{\mathrm{d}y^j}{\mathrm{d}s}\frac{\mathrm{d}y^k}{\mathrm{d}s}\mathrm{d}s \qquad (6.7.431)$$

which can also be written:

$$\mathrm{d}(\vec{v}\circ\vec{n})=(\partial_i v_k-v_i\Gamma_{kj}^i)\mathrm{d}y^j\frac{\mathrm{d}y^k}{\mathrm{d}s}=Dv_k\frac{\mathrm{d}y^k}{\mathrm{d}s} \qquad (6.7.432)$$

Where we have put:

$$\mathrm{D}v_k=(\partial_j v_k-v_i\Gamma_{kj}^i)\mathrm{d}y^i \qquad (6.7.433)$$

which are by definition the absolute differentials of the covariant components of the vector $\vec{v}$. We also define the "covariant derivative for 1-forms" (also named "connection" or "affine connection") by the relation:

$$\boxed{\nabla_j v_k=\partial_j v_k-v_i\Gamma_{kj}^i} \qquad (6.7.434)$$

Remark

In ancient or American textbooks this is often written in the form (which we will not use in this textbook):

$$v_{k;j}=v_{k,j}-v_i\Gamma_{kj}^i \qquad (6.7.435)$$

making use of the ";" to denote the covariant derivative and the "," for the partial differential.

Since the derivative of the product of two functions is the sum of the partial derivatives, then we also have:

$$\begin{aligned}\nabla_a(t_br_c)&=r_c\nabla_a t_b+t_b\nabla_a r_c=r_c(\partial_a t_b-t_e\Gamma_{ab}^e)+t_b(\partial_a r_c-r_e\Gamma_{ac}^e)\\&=r_c\partial_a t_b-r_ct_e\Gamma_{ab}^e+t_b\partial_a r_c-t_br_e\Gamma_{ac}^e=r_c\partial_a t_b+t_b\partial_a r_c-r_ct_e\Gamma_{ab}^e-t_br_e\Gamma_{ac}^e\\&=\partial_a(t_br_c)-r_ct_e\Gamma_{ab}^e-t_br_e\Gamma_{ac}^e\end{aligned} \qquad (6.7.436)$$

If we put $t_br_c\equiv\nabla_j v_i$ then we have (result which we will use after having proved the Ricci theorem to further determine the Einstein tensor necessary in the section of General Relativity):

$$\boxed{\nabla_k(\nabla_j v_i)=\partial_k(\nabla_j v_i)-(\nabla_j v_r)\Gamma_{ik}^r-(\nabla_r v_i)\Gamma_{jk}^r} \qquad (6.7.437)$$

In curvilinear coordinates, in order for the differential of a vector to be a vector, the two vectors of which we take the difference must be in the same point of space. In other words, one of the two infinitely close vectors must be transported in one way or another to the point where the second is located, and only after making the difference between the two vectors which are now in one and only one point of the same punctual space. The "parallel transport" operation must be defined in such a way that in cartesian coordinates (for the small example...), the difference of the components coincides with the ordinary difference $\mathrm{d}v_k$.

Thus, we have indeed in Cartesian coordinates:

$$\mathrm{D}v_k=(\partial_j v_k-v_i\Gamma_{kj}^i)\mathrm{d}y^i=\mathrm{d}v_k \tag{6.7.438}$$

since in this system: $\Gamma_{kj}^i=0$.

Thus, in curvilinear coordinates, the difference of the components of the two vectors after the transport of one of them to the point where the other is denoted δv_k such that we have:

$$\mathrm{D}v_k=(\partial_i v_k-v_i\Gamma_{kj}^i)\mathrm{d}y^j=\mathrm{d}v_k-\delta v_k \tag{6.7.439}$$

This brings us by identification to write:

$$\delta v_k=v_i\Gamma_{kj}^i\mathrm{d}y^i \tag{6.7.440}$$

But also to write the principle of least action (variational principle) in the tensorial form:

$$\mathrm{D}v_k=dv_k-\delta v_k=0 \tag{6.7.441}$$

Let us consider now a tensor of order two, product of two tensors of order one such that (as we have seen in our study of tensor compositions):

$$\begin{aligned}\delta(A_iB_j)=\delta A_{ij}=A_i\delta B_j+B_j\delta A_i&=A_iB_k\Gamma_{jk}^k\mathrm{d}y^h+B_jA_k\Gamma_{ih}^k\mathrm{d}y^h\\&=(A_iB_k\Gamma_{jh}^k+B_jA_k\Gamma_{ih}^k)\mathrm{d}y^k=\delta A_{ij}=(A_{ik}\Gamma_{jh}^k+B_{jk}\Gamma_{ih}^k)\mathrm{d}y^h\end{aligned} \tag{6.7.442}$$

Therefore:

$$\frac{\delta v_{ij}}{\mathrm{d}y^k}=\partial_h v_{ij}=(v_{ik}\Gamma_{jh}^k+v_{jk}\Gamma_{ih}^k) \tag{6.7.443}$$

hence (we take out the last two equalities just for aesthetics!):

$$\partial_k v_{ij}=(v_{ik}\Gamma_{jh}^k+v_{jk}\Gamma_{ih}^k) \tag{6.7.444}$$

A parallel transport is therefore an operation that takes a tangent vector and moves it along a path in space without turning it (relative to the space) or changing its length. In flat space we can say that the transported vector is parallel to the original vector at every point along the path. In curved space we cannot say such a thing. Let's use the spherical surface of Earth to show this! We start at the equator at longitude 0° holding an arrow pointing north:

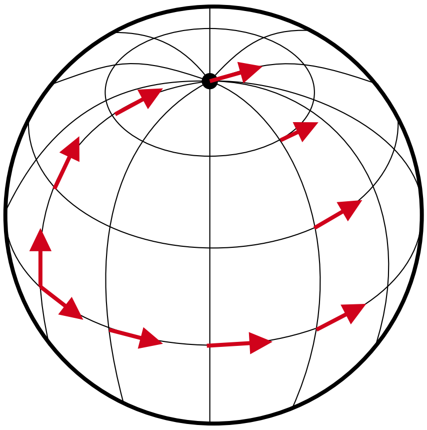

Figure 6.161: **Parallel transport illustration on a sphere**

We go along longitude 0° up to the North Pole, keeping our arrow parallel to the ground and pointing forward all the time. When we get to the North Pole our arrow is pointing in the direction of longitude 180°. Now we go South along longitude 90° East keeping our arrow perpendicular to our path as it was at the North Pole. When we get to the equator our arrow is pointing to the east. Finally, we go West along the equator until we get back to our starting point. We keep the arrow pointing backwards all the way. Though we did not turn the arrow all the way, we are now at the starting point with our arrow turned 90° relative to its original position. We surely can't say that it is now parallel to the original position. This means that the term "direction" cannot be defined globally in a curved space. We can only compare the direction of two vectors if they are at the same point.

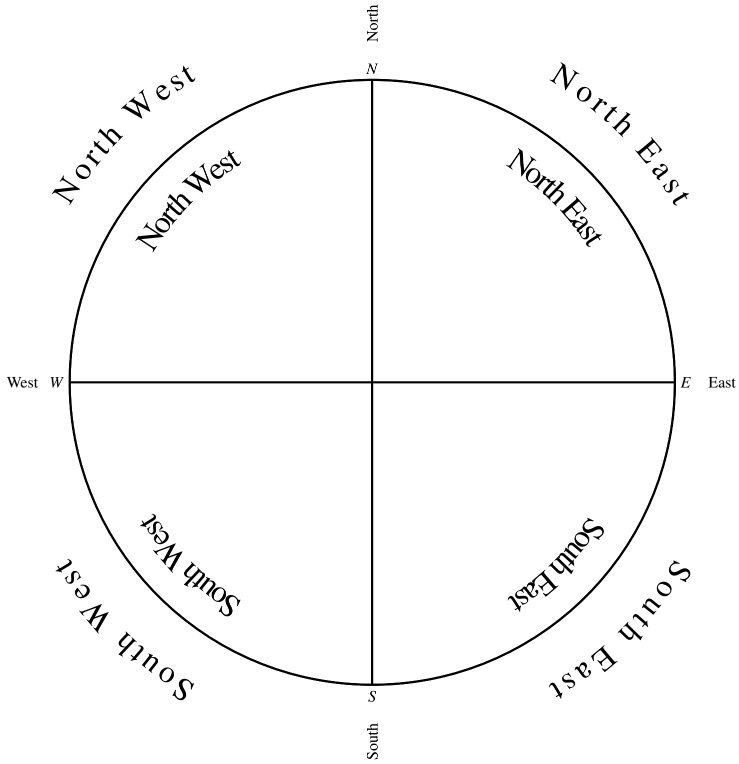

Figure 6.162: Reminder of cardinals names

Definitions (#6.7.266):

D1. "East" is one of the four cardinal directions or points of a compass. It is the opposite direction from West and is the direction from which the Sun rises on the Earth (at least at the day we write these lines...). The word "East" shouldn't be used in the field of geometry excepted when we deal with celestial objects that have a dipolar magnetic field or a sunrise and sunset however even some scientists sadly still associate the "East" with the concept of "Right"...

D2. "West" is one of the four cardinal directions or points of a compass. It is the opposite direction from East and is the direction from which the Sun set on the Earth (at least at the day we write these lines...). The word "West" shouldn't be used in the field of geometry excepted when we deal with celestial objects that have a dipolar magnetic field or a sunrise and sunset however even some scientists sadly still associated the "West" with the concept of "Left"...

D3. "North" is one of the four cardinal directions or points of a compass. It is the opposite of South and is perpendicular to East and West. The word "North" shouldn't be used in the field of geometry excepted when we deal with celestial objects that have a dipolar magnetic field however even some scientists sadly still associated the "North" with the concept of "Top/Up"...

D4. "South" is one of the four cardinal directions or points of a compass. It is the opposite of North and is perpendicular to East and West. The word "North" shouldn't be used in the field of geometry excepted when we deal with celestial objects that have a dipolar magnetic field however even some scientists sadly still associated the "South" with the concept of "Bottom/Down"... The South is differentiate from the North based on the physicist Ampere right hand rule (see section Magnetostatics 4010).

The fact that parallel transport along a closed loop changes the direction of a vector in a curved space but not in a flat space may lead to the idea of using it as a way to measure curvature. It turns out that if we choose a loop that is small enough around a point in a curved space, the amount of change in the direction of a vector that is parallel transported along it is proportional to the area enclosed by the loop. So, the ratio between the area of the loop and the amount of change in the direction of the vector (whatever way we chose to measure it) can be used as a measure to the curvature of the surface that includes the loop. Actually we define curvature by the value of this ratio.

The previous relation leads us to be able to write the metric in its variational form named "Ricci identity":

$$\boxed{\partial_h g_{ij}=g_{ik}\Gamma_{jh}^k+g_{jk}\Gamma_{ih}^k} \qquad (6.7.445)$$

But we also have since $g_{ij}=\vec{e}_i\circ\vec{e}_j$:

$$\mathrm{d}g_{ij}=\vec{e}_i\circ\mathrm{d}\vec{e}_j+\mathrm{d}\vec{e}_i\circ\vec{e}_j=\vec{e}_i\circ\omega_j^k\vec{e}_k+\omega_i^k\vec{e}_k\circ\vec{e}_j=\omega_j^k(\vec{e}_i\circ\vec{e}_k)+\omega_i^k(\vec{e}_k\circ\vec{e}_j) \qquad (6.7.446)$$

hence the identity:

$$\mathrm{d}g_{ij}=\omega_j^k g_{ik}+\omega_i^k g_{jk} \qquad (6.7.447)$$

With the both relations:

$$\mathrm{d}g_{ij}=\omega_j^k g_{ik}+\omega_i^k g_{jk} \qquad \text{and} \qquad \delta g_{ij}=(g_{ik}\Gamma_{jh}^k+g_{jk}\Gamma_{ih}^k)\mathrm{d}y^h \qquad (6.7.448)$$

and the absolute differential (which is simply generalized for a tensor of order two):

$$\mathrm{D}g_{ij}=\mathrm{d}g_{ij}-\delta g_{ij} \qquad (6.7.449)$$

we get:

$$\mathrm{D}g_{ij}=\omega_j^k g_{ik}+\omega_i^k g_{jk}-g_{ik}\Gamma_{jh}^k\mathrm{d}y^h-g_{jk}\Gamma_{ih}^k\mathrm{d}y^h \qquad (6.7.450)$$

Now, let us recall that we have by definition:

$$\omega_j^k=\Gamma_{jh}^k \mathrm{d}y^h \qquad \text{and} \qquad \omega_i^k=\Gamma_{ih}^k \mathrm{d}y^h \tag{6.7.451}$$

Hence finally:

$$\boxed{\mathrm{D}g_{ij}=0} \tag{6.7.452}$$

The absolute differential on a geodesic in the approximation of an infinitesimal transport of the fundamental tensor is therefore (as we could expect) zero. This is the "Ricci theorem". Some theoretical physicists then say that «*the covariant derivative kills the metric*» in the sense that the metric does not change on a space differential.

Finally, we also see that for a tensor of order two (the metric in particular) we have:

$$\mathrm{D}g_{ij}=\mathrm{d}g_{ij}-\delta g_{ij}=\mathrm{d}g_{ij}-g_{ik}\Gamma_{jh}^k \mathrm{d}y^h-g_{jk}\Gamma_{ih}^k \mathrm{d}y^h \tag{6.7.453}$$

We can therefore write the absolute differential which in this particular case is zero:

$$\mathrm{D}g_{ij}=(\partial_h g_{ij}-g_{ik}\Gamma_{jh}^k-g_{jk}\Gamma_{ih}^k)\mathrm{d}y^h=0 \tag{6.7.454}$$

And therefore the "covariant derivative of a $(0,2)$-form" of the metric is null:

$$\boxed{\frac{\mathrm{D}g_{ij}}{\mathrm{d}y^h}=\nabla_h g_{ij}=\partial_h g_{ij}-g_{ik}\Gamma_{jh}^k-g_{jk}\Gamma_{ih}^k=0} \tag{6.7.455}$$

Remark

The reader will have to remember for the definition of the Einstein tensor that:

$$\nabla_k g_{ij}=0 \qquad \text{and} \qquad \nabla_k g_{ij}=\partial_h g_{ij}-g_{ik}\Gamma_{jh}^k-g_{jk}\Gamma_{ih}^k=0 \tag{6.7.456}$$

and that this is another way of expressing that an infinitesimal variation on a geodesic according to the principle of least action kills the metric. We will therefore work from now on (as before) with non-linear differential equations that must be integrated to find the behaviour of matter in a given space.

In general, if T is an (r,s) tensor field (we will need that during our study of General Relativity), then ∇T is an $(r,s+1)$-tensor field given by:

$$(\nabla T)(\eta_1,\ldots,\eta_r,X,Y_1,\ldots,Y_s)=(\nabla_X T)(\eta_1,\ldots,\eta_r,Y_1,\ldots,Y_s) \tag{6.7.457}$$

where the latter expression is intrinsically defined by the equation:

$$\begin{aligned}\nabla_X(T(\eta_1,\ldots,\eta_r,Y_1,\ldots,Y_s))=&(\nabla_X T)(\eta_1,\ldots,\eta_r,Y_1,\ldots,Y_s)\\&+\sum_{i=1}^{r}T(\eta_1,\ldots,\eta_{i-1},\nabla_X\eta_i,\eta_{i+1},\ldots,\eta_r,Y_1,\ldots,Y_s)\\&+\sum_{j=1}^{s}T(\eta_1,\ldots,\eta_r,Y_1,\ldots,Y_{j-1},\nabla_X Y_j,Y_{j+1},\ldots,Y_s)\end{aligned} \tag{6.7.458}$$

In particular, if T is a $(1,1)$-tensor, then $(\nabla_X T)(\eta, Y)$ is intrinsically defined by the equation:

$$\nabla_X(T(\eta,Y)) = (\nabla_X T)(\eta,Y) + T(\nabla_X \eta, Y) + T(\eta, \nabla_X Y) \tag{6.7.459}$$

and therefore the correct expression for $(\nabla_X T)(\eta, Y)$ is:

$$(\nabla_X T)(\eta,Y) := \nabla_X(T(\eta,Y)) - T(\nabla_X \eta, Y) - T(\eta, \nabla_X Y) \tag{6.7.460}$$

This will help us to derive a special case of:

$$\begin{aligned} T^{\mu_1 \ldots \mu_r}{}_{\nu_1 \ldots \nu_s;\rho} = T^{\mu_1 \ldots \mu_r}{}_{\nu_1 \ldots \nu_s,\rho} &+ \Gamma^{\mu_1}_{\sigma\rho} T^{\sigma \ldots \mu_r}{}_{\nu_1 \ldots \nu_s} + \ldots + \Gamma^{\mu_r}_{\sigma\rho} T^{\mu_1 \ldots \sigma}{}_{\nu_1 \ldots \nu_s} \\ &- \Gamma^{\sigma}_{\nu_1\rho} T^{\mu_1 \ldots \mu_r}{}_{\sigma \ldots \nu_s} - \ldots - \Gamma^{\sigma}_{\nu_s\rho} T^{\mu_1 \ldots \mu_r}{}_{\nu_1 \ldots \sigma} \end{aligned} \tag{6.7.461}$$

for the case of a $(1,1)$-tensor (as we will have during our Study of General Relativity).

So, by the definition above in the case of a $(1,1)$-tensor we have $T^{\mu}{}_{\nu;\rho} := \nabla_{e_\rho} T(f^\mu, e_\nu)$, where we are using f^μ and e_v for $\mathrm{d}x^\mu$ and $\partial / \partial x^\nu$.

Hence we have (it's very not obvious so maybe in the future we will detail the process more or found another approach):

$$\nabla_{e_\rho} T(f^\mu, e_\nu) := \nabla_{e_\rho}(T(f^\mu, e_\nu)) - T(\nabla_{e_\rho} f^\mu, e_\nu) - T(f^\mu, \nabla_{e_\rho} e_\nu) \tag{6.7.462}$$

The first and third terms are easily evaluated:

$$\nabla_{e_\rho}(T(f^\mu, e_\nu)) = e_\rho(T(f^\mu, e_\nu)) = e_\rho(T^\mu{}_\nu) = T^\mu{}_{\nu,\rho} \tag{6.7.463}$$

$$T(f^\mu, \nabla_{e_\rho} e_\nu) = T(f^\mu, \Gamma^\sigma_{\nu\rho} e_\sigma) = \Gamma^\sigma_{\nu\rho} T(f^\mu, e_\sigma) = \Gamma^\sigma_{\nu\rho} T^\mu{}_\sigma \tag{6.7.464}$$

For the second term, since f^μ is a $(0,1)$-tensor field, ∇f^μ is a $(0,2)$-tensor field and hence $\nabla_{e_\rho} f^\mu$, for fixed e_ρ, is a $(0,1)$-tensor field. We evaluate:

$$\begin{aligned} (\nabla_{e_\rho} f^\mu)_\lambda = \nabla_{e_\rho} f^\mu(e_\lambda) &:= \nabla_{e_\rho}(f^\mu(e_\lambda)) - f^\mu(\nabla_{e_\rho} e_\lambda) \\ &= e_\rho(\delta^\mu_\lambda) - f^\mu(\Gamma^\sigma_{\lambda\rho} e_\sigma) = 0 - \Gamma^\sigma_{\lambda\rho} f^\mu(e_\sigma) = -\Gamma^\sigma_{\lambda\rho}\delta^\mu_\sigma = -\Gamma^\mu_{\lambda\rho} = -\Gamma^\mu_{\sigma\rho}\delta^\sigma_\lambda \\ &= -\Gamma^\mu_{\sigma\rho} f^\sigma(e_\lambda) \end{aligned} \tag{6.7.465}$$

Therefore $\nabla_{e_\rho} f^\mu = -\Gamma^\mu_{\sigma\rho} f^\sigma$ and hence:

$$T(\nabla_{e_\rho} f^\mu, e_\nu) = T(-\Gamma^\mu_{\sigma\rho} f^\sigma, e_\nu) = -\Gamma^\mu_{\sigma\rho} T(f^\sigma, e_\nu) = -\Gamma^\mu_{\sigma\rho} T^\sigma{}_\nu \tag{6.7.466}$$

Thus, we have:

$$T^\mu{}_{\nu;\rho} = T^\mu{}_{\nu,\rho} + \Gamma^\mu_{\sigma\rho} T^\sigma{}_\nu - \Gamma^\sigma_{\nu\rho} T^\mu{}_\sigma \tag{6.7.467}$$

Sometimes denoted in some textbooks as:

$$D_a T^b_c = \partial_a T^b_c + \Gamma^b_{fa} T^f_c - \Gamma^h_{ca} T^b_h \tag{6.7.468}$$

✍**Example:**

Let's try to verify this by calculating one component of the covariant differentiation in the spherical coordinates.

Let us recall first that the diagonal metric of the 2-sphere surface $\mathcal{S}^2$ expression is (see section Differential Geometry 2884):

$$\begin{gathered}g_{ij}=\begin{bmatrix}g_{\theta\theta} & g_{\theta\phi}\\ g_{\phi\theta} & g_{\phi\phi}\end{bmatrix}=\begin{bmatrix}R^2 & 0\\ 0 & R^2\sin^2(\theta)\end{bmatrix}\\ g^{ij}=\begin{bmatrix}g^{\theta\theta} & g^{\theta\phi}\\ g^{\phi\theta} & g^{\phi\phi}\end{bmatrix}=\begin{bmatrix}\frac{1}{R^2} & 0\\ 0 & \frac{1}{R^2\sin^2(\theta)}\end{bmatrix}\end{gathered}\tag{6.7.469}$$

If we were to calculate the component $g_{\phi\phi;\theta}$, we should then write:

$$\nabla_\theta g_{\phi\phi}=\frac{\partial g_{\phi\phi}}{\partial\theta}-g_{\alpha\phi}\Gamma_{\phi\theta}^{\alpha}-g_{\phi\alpha}\Gamma_{\phi\theta}^{\alpha}\tag{6.7.470}$$

But $g_{ij}\neq 0$ only if $i=j$, based on the above expressions, so we can simplify this relation:

$$\nabla_\theta g_{\phi\phi}=\frac{\partial g_{\phi\phi}}{\partial\theta}-g_{\phi\phi}\Gamma_{\phi\theta}^{\phi}-g_{\phi\phi}\Gamma_{\phi\theta}^{\phi}=\frac{\partial g_{\phi\phi}}{\partial\theta}-2g_{\phi\phi}\Gamma_{\phi\theta}^{\phi}\tag{6.7.471}$$

As (see section Differential and Integral Calculus page 1475):

$$\frac{\partial g_{\phi\phi}}{\partial\theta}=\frac{\partial R^2\sin^2(\theta)}{\partial\theta}=2R^2\sin(\theta)\cos(\theta)\tag{6.7.472}$$

Further below (see page 2137) we will prove that for $\mathcal{S}^2$ we have:

$$\Gamma_{ij}^{\theta}=\begin{bmatrix}0 & 0\\ 0 & -\sin(\theta)\cos(\theta)\end{bmatrix}\qquad\Gamma_{ij}^{\phi}=\begin{bmatrix}0 & \cot(\theta)\\ \cot(\theta) & 0\end{bmatrix}=\begin{bmatrix}0 & \frac{\cos(\theta)}{\sin(\theta)}\\ \frac{\cos(\theta)}{\sin(\theta)} & 0\end{bmatrix}\tag{6.7.473}$$

So that:

$$g_{\phi\phi}\Gamma_{\phi\theta}^{\phi}=R^2\sin^2(\theta)\frac{\cos(\theta)}{\sin(\theta)}=R^2\sin(\theta)\cos(\theta)\tag{6.7.474}$$

Finally, we confirm that this component of the covariant derivative with respect to θ equals also zero in a polar coordinates system, as expected:

$$\nabla_\theta g_{\phi\phi}=\frac{\partial g_{\phi\phi}}{\partial\theta}-2g_{\phi\phi}\Gamma_{\theta\phi}^{\phi}=2R^2\sin(\theta)\cos(\theta)-2R^2\sin(\theta)\cos(\theta)=0\tag{6.7.475}$$

Let us now determine an expression which will be very useful in General Relativity when we will determine the Einstein field equations (another way of expressing that the covariant derivative of the metric is null)!

First let us compute (we switch the notation so that reader can take the habit to see the different common one):

$$D_a g_{bc} = \partial_a g_{bc} - \Gamma_{ba}^{f} g_{fc} - \Gamma_{ca}^{h} g_{hc} \tag{6.7.476}$$

As we have:

$$g_{bc} = \vec{e}_b \circ \vec{e}_c \Rightarrow \partial_a g_{bc} = \frac{\partial \vec{e}_b}{\partial x^a} \circ \vec{e}_c + \vec{e}_b \circ \frac{\partial \vec{e}_c}{\partial x^a} \tag{6.7.477}$$

Therefore:

$$\partial_a g_{bc} = \Gamma_{ba}^{f} \underbrace{\vec{e}_f \circ \vec{e}_c}_{g_{fc}} - \Gamma_{ca}^{h} \underbrace{\vec{e}_h \circ \vec{e}_c}_{g_{hc}} \tag{6.7.478}$$

Hence:

$$D_a g_{bc} = \partial_a g_{bc} - \Gamma_{ba}^{f} g_{fc} - \Gamma_{ca}^{h} g_{hc} = 0 \tag{6.7.479}$$

Let us perform now the contracted multiplication of:

$$\nabla_k g_{ij} = \partial_h g_{ij} - g_{ik} \Gamma_{jh}^{k} - g_{jk} \Gamma_{ih}^{k} = 0 \tag{6.7.480}$$

by g^{ij}, it then comes by using the relation $g^{ij} g_{jl} = \delta_i^l$ (which we had proved much earlier above) that:

$$g^{ij} \partial_h g_{ij} - g^{ij} g_{ik} \Gamma_{jh}^{k} - g^{ij} g_{jk} \Gamma_{ih}^{k} = g^{ij} \partial_h g_{ij} - \delta_j^k \Gamma_{jh}^{k} - \delta_i^k \Gamma_{ih}^{k} = 0 \tag{6.7.481}$$

hence the relation:

$$g^{ij} \partial_h g_{ij} - \Gamma_{jh}^{j} - \Gamma_{ih}^{i} = 0 \tag{6.7.482}$$

The quantities Γ_{jh}^{j} and Γ_{ih}^{h} representing the same sums, we then have:

$$g^{ij} \partial_h g_{ij} = 2\Gamma_{ih}^{i} \tag{6.7.483}$$

Theorem 6.46. Let us consider now the determinant g of the quantities g_{ij}. The derivation of the determinant gives us:

$$\partial_h g = g g_{ij} \partial_h g_{ij} \Leftrightarrow \partial_h g_{ij} = \frac{\partial_k g}{g g^{ij}} \tag{6.7.484}$$

Proof 6.46.1. Given any variable that we choose here as being the time t only to simplify the notations of the calculations that will follow. When the main part of the development is completed, the result can be adapted to any other variable! We will write for what will follow g_j the elements of the j-th column of g_{ij}.

For the following developments, we define the notations:

$$g = \det(g_1, g_2, \ldots, g_n) \qquad \dot{g} = d_t g \qquad \dot{g}_j = \mathrm{d}_t g_j \qquad \dot{g}_{ij} = \mathrm{d}_t g_{ij} \tag{6.7.485}$$

The rule of derivation of a functional determinant is given for recall (see section Linear Algebra page 1974) by:

$$\dot{g} = \det(\dot{g}_1, g_2, \ldots, g_n) + \det(g_1, \dot{g}_2, \ldots, g_n) + \ldots + \det(g_1, g_2, \ldots, \dot{g}_n) \tag{6.7.486}$$

By considering the first determinant, by using the minors (see section Linear Algebra page 1974) for the development of its first column:

$$\alpha_{i1}\dot{g}_{i1} \tag{6.7.487}$$

For the j-th determinant, it comes:

$$\alpha_{ij}\dot{g}_{ij} \tag{6.7.488}$$

Thus:

$$\dot{g} = \alpha_{ij}\dot{g}_{ij} \qquad \text{or} \qquad \dot{g} = \alpha_{ij}g_{ij} \tag{6.7.489}$$

Now, we have demonstrated much earlier that the metric tensor is its own inverse. Therefore:

$$g^{ij} = g_{ij}^{-1} \tag{6.7.490}$$

This allows us to write:

$$gg^{ij} = \alpha_{ij} \tag{6.7.491}$$

and therefore:

$$\dot{g} = g\dot{g}_{ij}g^{ij} \tag{6.7.492}$$

what is also written (following the conventions defined at the beginning of the proof):

$$\mathrm{d}_t g = g\mathrm{d}_t g_{ij}g^{ij} \tag{6.7.493}$$

where the reader must therefore be careful not to read badly, typically thinking that the derivative d_t in the right-hand term derives everything $(g_{ij}g^{ij})$... while it only derives g_{ij}.

However, we can adopt another variable. Let h be this other variable:

$$\partial_h g = gg^{ij}\partial_h g_{ij} \tag{6.7.494}$$

Either by rearranging:

$$\boxed{\partial_h g_{ij} = \left(gg^{ij}\right)^{-1}\partial_h g = \frac{1}{g}\left(g^{ij}\right)^{-1}\partial_h g} \tag{6.7.495}$$

This is what we wanted to prove.

■ Q.E.D.

Now by combining:

$$\Gamma^i_{ih} = \frac{1}{2}g^{ij}\partial_h g_{ij} \tag{6.7.496}$$

Demonstrated earlier above and the result we have just proved:

$$\partial_h g_{ij} = \frac{1}{g}\left(g^{ij}\right)^{-1}\partial_h g \tag{6.7.497}$$

it comes:

$$\Gamma^i_{ih}=\frac{1}{2}g^{ij}\partial_h g_{ij}=\frac{1}{2}g^{ij}\left(\frac{1}{g}(g_{ij})^{-1}\partial_h g\right)=\frac{1}{2g}\partial_h g \qquad (6.7.498)$$

Therefore we have:

$$g^{ij}\partial_h g_{ij}=\frac{\partial_h g}{g}=2\Gamma^i_{ih} \qquad (6.7.499)$$

Let us prove that it is possible to derive this last relation from the following important equality:

$$\boxed{\Gamma^i_{ih}=\frac{1}{\sqrt{g}}\partial_h\sqrt{g}} \qquad (6.7.500)$$

Indeed:

$$\Gamma^i_{ih}=\frac{1}{\sqrt{g}}\partial_h\sqrt{g}=\frac{1}{\sqrt{g}}\left(\frac{1}{2\sqrt{g}}\partial_h g\right)=\frac{1}{2g}\partial_h g \qquad (6.7.501)$$

This relation does not mean much until we will make a more explicit use of it in our study of General Relativity (see section General Relativity page 5720).

Let us now determine the second covariant derivative of the metric tensor. Let us remember before we go further (because it is important) that we had obtained:

$$\nabla_h g_{ij}=\partial_h g_{ij}-g_{ik}\Gamma^k_{jh}-g_{jk}\Gamma^k_{ih} \qquad (6.7.502)$$

6.7.12 Riemann-Christoffel symbols

Before reading what follows ... We want to remind the reader again that the writing of this section is not finished (as most chapters in the book)! Thus, we still have to illustrate the abstract notions that will follow with concrete practical examples but that are example outside of the special case of General Relativity!

Let us recall that we have demonstrated earlier above that:

$$\nabla_k(\nabla_j v_i)=\partial_k(\nabla_j v_i)-(\nabla_j v_r)\Gamma^r_{ik}-(\nabla_r v_i)\Gamma^r_{jk} \qquad (6.7.503)$$

This relation means, exception of an interpretation error from the writer of those linear as sometimes interpreting Tensor Calculus result is a pain in the a.., that the covariant derivative of a tensor of order two - such as the metric - on a geodesic path in two perpendicular directions (the second covariant derivative making it possible to the "perpendicular geodesic" between the two geodesics infinitely close to the first covariant derivative). We know already that such a shift is "parallel transport".

By substituting in it:

$$\nabla_j v_i=\partial_j v_i-\Gamma^l_{ji}v_l \qquad (6.7.504)$$

We then have:

$$\begin{aligned}\nabla_k(\nabla_j v_i)&=\partial_k(\partial_j v_i-\Gamma^l_{ji}v_l)-(\partial_j v_r-\Gamma^l_{jr}v_l)\Gamma^r_{ik}-(\partial_r v_i-\Gamma^l_{ri}v_l)\Gamma^r_{jk}\\&=\partial_{kj}v_i-(\partial_k\Gamma^l_{ji})v_l-\Gamma^l_{ji}(\partial_k v_l)-\Gamma^r_{ik}\partial_j v_r+\Gamma^l_{jr}\Gamma^r_{ik}v_l-\Gamma^r_{jk}\partial_r v_i+\Gamma^r_{jk}\Gamma^l_{ri}v_l\end{aligned}\tag{6.7.505}$$

Let us now switch the indices j and k in the previous expression to have a differential with respect to another path:

$$\nabla_j(\nabla_k v_i)=\partial_{jk}v_i-(\partial_j\Gamma^l_{ki})v_l-\Gamma^l_{ki}(\partial_j v_l)-\Gamma^r_{ij}\partial_k v_r+\Gamma^l_{kr}\Gamma^r_{ij}v_l-\Gamma^r_{kj}\partial_r v_i+\Gamma^r_{kj}\Gamma^l_{ri}v_l\tag{6.7.506}$$

Assuming that the components satisfy the classical properties $\partial_{kj}v_i=\partial_{jk}v_i$, we get by subtraction of the two previous expressions:

$$\begin{array}{rl}&\nabla_k(\nabla_j v_i)=\partial_{kj}v_i-(\partial_k\Gamma^l_{ji})v_l-\Gamma^l_{ji}(\partial_k v_l)-\Gamma^r_{ik}\partial_j v_r+\Gamma^l_{jr}\Gamma^r_{ik}v_l-\Gamma^r_{jk}\partial_r v_i+\Gamma^r_{jk}\Gamma^l_{ri}v_l\\-&\nabla_j(\nabla_k v_i)=\partial_{jk}v_i-(\partial_j\Gamma^l_{ki})v_l-\Gamma^l_{ki}(\partial_j v_l)-\Gamma^r_{ij}\partial_k v_r+\Gamma^l_{kr}\Gamma^r_{ij}v_l-\Gamma^r_{kj}\partial_r v_i+\Gamma^r_{kj}\Gamma^l_{ri}v_l\\\hline&\nabla_k(\nabla_j v_i)-\nabla_j(\nabla_k v_i)=\underbrace{(\partial_{kj}v_i-\partial_{jk}v_i)}_{=0}+(\partial_j\Gamma^l_{ki}-\partial_k\Gamma^l_{ji})v_l+(\Gamma^l_{ki}\partial_j-\Gamma^l_{ji}\partial_k)v_l\\&\qquad+(\Gamma^r_{ij}\partial_k-\Gamma^r_{ik}\partial_j)v_r+(\Gamma^l_{jr}\Gamma^r_{ik}-\Gamma^l_{kr}\Gamma^r_{ij})v_l+(\Gamma^r_{kj}-\Gamma^r_{jk})\partial_r v_i+(\Gamma^r_{jk}\Gamma^l_{ri}-\Gamma^r_{kj}\Gamma^l_{ri})v_l\end{array}\tag{6.7.507}$$

And since we have proved that in the case of a symmetric metric we have:

$$\Gamma^r_{jk}=\Gamma^r_{kj}\tag{6.7.508}$$

We have therefore:

$$\begin{aligned}\nabla_k(\nabla_j v_i)-\nabla_j(\nabla_k v_i)=&(\partial_j\Gamma^l_{ki}-\partial_k\Gamma^l_{ji})v_l+(\Gamma^l_{ki}\partial_j-\Gamma^l_{ji}\partial_k)v_l\\&+(\Gamma^r_{ij}\partial_k-\Gamma^r_{ik}\partial_j)v_r+(\Gamma^l_{jr}\Gamma^r_{ik}-\Gamma^l_{kr}\Gamma^r_{ij})v_l+\underbrace{(\Gamma^r_{kj}-\Gamma^r_{jk})}_{=0}\partial_r v_i+\underbrace{(\Gamma^r_{jk}\Gamma^l_{ri}-\Gamma^r_{kj}\Gamma^l_{ri})}_{=0}v_l\end{aligned}\tag{6.7.509}$$

Remark

The fact of having in the case of a symmetric metric $\Gamma^r_{jk}=\Gamma^r_{kj}$ and which vanishes in the preceding relation, leads many practitioners to define what we name the "torsion tensor" or "torsor" (but in reality it is a particular case of a more general relation which belongs to the domain of differential geometry). Thus, we define the torsion tensor as:

$$T^k_{ih}=\Gamma^k_{ij}-\Gamma^k_{ji}\tag{6.7.510}$$

and in the case of a symmetric metric (Euclidean space), the torsion is zero by extension as we have already seen it! In fact, the Einstein field equations which we shall prove later implicitly implies a symmetric metric with zero torsion. However, it is possible to proved that a non-symmetric tensor can always be decomposed into a symmetric and non-symmetric tensor (this is trivial because it is like separating a complete matrix in the sum of a matrix having a diagonal of non-zero component that are and another matrix having the diagonal zero).

It then remains:

$$\begin{aligned}\nabla_k(\nabla_j v_i)-\nabla_j(\nabla_k v_i)=&(\partial_j\Gamma^l_{ki}-\partial_k\Gamma^l_{ji})v_l+(\Gamma^l_{ki}\partial_j-\Gamma^l_{ji}\partial_k)v_l\\&+(\Gamma^r_{ij}\partial_k-\Gamma^r_{ik}\partial_j)v_r+(\Gamma^l_{jr}\Gamma^r_{ik}-\Gamma^l_{kr}\Gamma^r_{ij})v_l\end{aligned}\tag{6.7.511}$$

Since parallel transport takes place on infinitely close geodesic paths, we take the limit:

$$\partial_j v_l, \partial_k v_l, \partial_k v_r, \partial_j v_r \longrightarrow 0 \tag{6.7.512}$$

Which mainly underlies the fact that the velocity field is almost equal in two infinitely close parallel points.

It then remains:

$$\boxed{\nabla_k(\nabla_j v_i) - \nabla_j(\nabla_k v_i) \cong (\partial_j \Gamma_{ki}^l - \partial_k \Gamma_{ji}^l + \Gamma_{jr}^l \Gamma_{ik}^r - \Gamma_{kr}^l \Gamma_{ij}^r) v_l} \tag{6.7.513}$$

This relation expresses the fact that, like gravity, the curvature of space-time causes a mutual acceleration between the geodesics! Moreover, it is easy to see that the mutual acceleration between the geodesics is zero if the Riemann-Christoffel tensors are null (typically in Cartesian coordinates, in extenso it means for a flat time-space). This is exactly what we expect of gravity: if we do not observe any acceleration, the curvature (we shall now define what it is) is zero and if the curvature is zero, we observe no acceleration. Morale of the story: the gravity is curvature and the curvature is gravity !!

We see that the quantity in parentheses is a tensor of order four that we will write on this site as following (because there are several traditions in the way to write it...):

$$\boxed{R_{i,jk}^l = \partial_j \Gamma_{ik}^l - \partial_k \Gamma_{ij}^l + \Gamma_{ik}^r \Gamma_{jr}^l - \Gamma_{ij}^r \Gamma_{kr}^l} \tag{6.7.514}$$

and which summarizes itself the parallel transport and the fact that gravity and geometry of space are linked together. Obviously, if the metric is of Minkowski type (or tends to a metric of Minkowski under certain conditions), then $R_{i,jk}^l$ is zero! Very rare authors write this last equality in the (unhappy ....) form:

$$R_{i,jk}^l = 2\Gamma_{i[k,j]}^l + 2\Gamma_{i[k}^r \Gamma_{j]r}^l \tag{6.7.515}$$

The tensor $R_{i,jk}^l$ is named the "Riemann-Christoffel tensor" or "Riemannian space tensor". The curvature of a Riemannian space can also be characterized using this tensor.

A fourth-rank tensor has $4^4 = 256$ components as we know. However, because of that fact that in many situations the metric is symmetric, the number of algebraically independent components of Riemann-Christoffel tensor is only 20.

If we multiply the tensor $R_{i,rs}^k$ by g_{jk}, then we have the covariant components of this tensor such that:

$$\boxed{R_{ij,rs} = g_{jk} R_{i,rs}^k} \tag{6.7.516}$$

and given the following relations that we proved earlier above:

$$g_{jk} \Gamma_{rl}^k = \Gamma_{rjl} \qquad g_{jk} \Gamma_{sl}^k = \Gamma_{sjl} \tag{6.7.517}$$

Therefore we get:

$$\begin{aligned} g_{jk} R_{i,rs}^k &= g_{jk} \partial_r \Gamma_{is}^k - g_{jk} \partial_s \Gamma_{ir}^k + g_{jk} \Gamma_{is}^l \Gamma_{rl}^k - g_{jk} \Gamma_{ir}^l \Gamma_{sl}^k \\ &= g_{jk} \partial_r \Gamma_{is}^k - g_{jk} \partial_s \Gamma_{ir}^k + \Gamma_{is}^l \Gamma_{rjl} - \Gamma_{ir}^l \Gamma_{sjl} \end{aligned} \tag{6.7.518}$$

and let us replace the quantities $g_{jk}\partial_r\Gamma^k_{is}$ by $\partial_r\left(g_{jk}\Gamma^k_{is}\right)-\Gamma^k_{is}\partial_r g_{jk}$. We then get:

$$\begin{aligned}g_{jk}R^k_{i,rs}&=(\partial_r(g_{jk}\Gamma^k_{is})-\Gamma^k_{is}\partial_r g_{jk})-(\partial_s(g_{jk}\Gamma^k_{ir})-\Gamma^k_{ir}\partial_s g_{jk})+\Gamma^l_{is}\Gamma_{rjl}-\Gamma^l_{ir}\Gamma_{sjl}\\&=\partial_r(g_{jk}\Gamma^k_{is})-\partial_s(g_{jk}\Gamma^k_{ir})+(\Gamma^l_{is}\Gamma_{rjl}-\Gamma^k_{is}\partial_r g_{jk})-(\Gamma^l_{ir}\Gamma_{sjl}-\Gamma^k_{ir}\partial_s g_{jk})\\&=\partial_r(g_{jk}\Gamma^k_{is})-\partial_s(g_{jk}\Gamma^k_{ir})+(\Gamma^l_{is}\Gamma_{rjl}-\Gamma^l_{is}\partial_r g_{jl})-(\Gamma^l_{ir}\Gamma_{sjl}-\Gamma^l_{ir}\partial_s g_{jl})\\&=\partial_r(g_{jk}\Gamma^k_{is})-\partial_s(g_{jk}\Gamma^k_{ir})+\Gamma^l_{is}(\Gamma_{rjl}-\partial_r g_{jl})-\Gamma^l_{ir}(\Gamma_{sjl}-\partial_s g_{jl})\end{aligned}\tag{6.7.519}$$

We also proved earlier before that:

$$\partial_k g_{ij}=\Gamma_{kji}+\Gamma_{kij}\Rightarrow\Gamma_{kij}-\partial_k g_{ij}=-\Gamma_{kji}\tag{6.7.520}$$

Hence:

$$g_{jk}R^k_{i,rs}=\partial_r(g_{jk}\Gamma^k_{is})-\partial_s(g_{jk}\Gamma^k_{ir})-\Gamma^l_{is}\Gamma_{rlj}+\Gamma^l_{ir}\Gamma_{slj}\tag{6.7.521}$$

and as:

$$g_{jk}\Gamma^k_{is}=\Gamma_{ijs}\qquad\qquad g_{jk}\Gamma^k_{ir}=\Gamma_{ijr}\tag{6.7.522}$$

we get:

$$g_{jk}R^k_{i,rs}=\partial_r\Gamma_{ijs}-\partial_s\Gamma_{ijr}-\Gamma^l_{is}\Gamma_{rlj}+\Gamma^l_{ir}\Gamma_{slj}\tag{6.7.523}$$

and we also proved that:

$$\Gamma_{kji}=\frac{1}{2}\left(\partial_k g_{ij}+\partial_i g_{jk}-\partial_j g_{ki}\right)\tag{6.7.524}$$

Hence:

$$\partial_r\Gamma_{ijs}=\frac{1}{2}\left(\partial_{ri}g_{sj}+\partial_{rs}g_{ji}-\partial_{rj}g_{is}\right)\tag{6.7.525}$$

And by reporting them into the prior-previous relation, we get:

$$\begin{aligned}R_{ij,rs}=g_{jk}R^k_{i,rs}&=\frac{1}{2}\left(\partial_{ri}g_{sj}+\cancel{\partial_{rs}g_{ji}}-\partial_{rj}g_{is}\right)-\frac{1}{2}\left(\partial_{si}g_{rj}+\cancel{\partial_{sr}g_{ji}}-\partial_{sj}g_{ir}\right)\\-\Gamma^l_{is}\Gamma_{rlj}+\Gamma^l_{ir}\Gamma_{slj}&=\frac{1}{2}\left(\partial_{ri}g_{sj}+\partial_{sj}g_{ir}-\partial_{rj}g_{is}-\partial_{si}g_{rj}\right)-\Gamma^l_{is}\Gamma_{rlj}+\Gamma^l_{ir}\Gamma_{slj}\end{aligned}\tag{6.7.526}$$

Finally, we get for the covariant expression of the Riemann-Christoffel tensor:

$$\boxed{R_{ij,rs}=\frac{1}{2}\left(\partial_{ri}g_{sj}+\partial_{sj}g_{ir}-\partial_{rj}g_{is}-\partial_{si}g_{rj}\right)-\Gamma^l_{is}\Gamma_{rlj}+\Gamma^l_{ir}\Gamma_{slj}}\tag{6.7.527}$$

It should be noticed that the Riemann-Christoffel tensor is therefore antisymmetric:

$$\boxed{R_{ij,rs}=-R_{ij,sr}}\tag{6.7.528}$$

and that in the parenthesis of the prior-previous relation we have only double partial derivatives, while outside of the parenthesis the Christoffel symbols contain only simple partial derivatives!

Finally, the permutation of the indices ij and rs as a block gives us as a consequence of the symmetry of the g_{ij} and by inverting their derivation order:

$$\boxed{R_{ij,rs}=R_{rs,ij}} \tag{6.7.529}$$

Let us now perform a circular permutation on the indices j, r, s in the expression (obtained just above)

$$R_{ij,rs}=\frac{1}{2}\left(\partial_{ri}g_{sj}+\partial_{sj}g_{ir}-\partial_{rj}g_{is}-\partial_{si}g_{rj}\right)-\Gamma_{is}^{l}\Gamma_{rlj}+\Gamma_{ir}^{l}\Gamma_{slj} \tag{6.7.530}$$

then we get:

$$\begin{aligned}R_{ir,sj}&=\frac{1}{2}\left(\partial_{jr}g_{is}+\partial_{is}g_{jr}-\partial_{rs}g_{ij}-\partial_{ij}g_{rs}\right)-\Gamma_{ij}^{l}\Gamma_{slr}+\Gamma_{is}^{l}\Gamma_{jlr}\\R_{is,jr}&=\frac{1}{2}\left(\partial_{rs}g_{ij}+\partial_{ij}g_{rs}-\partial_{js}g_{ir}-\partial_{ir}g_{js}\right)-\Gamma_{ir}^{l}\Gamma_{jls}+\Gamma_{ij}^{l}\Gamma_{rls}\end{aligned} \tag{6.7.531}$$

and we get (it is very simple to control by summing the three lines above):

$$\boxed{R_{ij,rs}+R_{ir,sj}+R_{is,jr}=0} \tag{6.7.532}$$

The previous identity is named the "first Bianchi identity" or also "Bianchi algebraic identity" and it highlights the cyclicity property of the Riemann-Christoffel tensor. In reality, we should not use the word "identity" since it is verified only (at least to my knowledge) in the case of a symmetric metric tensor (otherwise, the torsion is not zero for recall!).

The reader will observe that it is immediate that this last relation is satisfied in the case of the Minkowski metric, since if at all points the partial derivative of the metric is zero we have:

$$\partial_{\sigma}g_{\mu\nu}=0\Rightarrow\Gamma_{\mu\nu}^{\rho}=0\Rightarrow R_{\sigma\mu,\nu}^{\rho}=0 \tag{6.7.533}$$

And we will see in the section of General Relativity that this first identity will serve as a basis for the construction of the Schwarzschild metric.

If the metric is of the Minkowski type (we change the notations of the indices to be more in conformity with the usual writings in general relativity) then it is immediate that we also have:

$$\boxed{\partial_{\lambda}R_{\alpha\beta,\mu\nu}+\partial_{\nu}R_{\alpha\beta,\lambda\mu}+\partial_{\mu}R_{\alpha\beta,\nu\lambda}=0} \tag{6.7.534}$$

But in the case where the metric is not of the Minkowski type, this latter relation can be satisfied and has an interest only if and only if the chosen metric is decomposable in Taylor series whose first partial derivatives are zero at 0 (see the section of Differential Geometry for such Taylor series!).

This relation is valid only in the case of a "locally inertial frame (LIF)" in which all Christoffel symbols cancel each other but not their derivatives.

By extension:

$$\boxed{\nabla_{\lambda}R_{\alpha\beta,\mu\nu}+\nabla_{\nu}R_{\alpha\beta,\lambda\mu}+\nabla_{\mu}R_{\alpha\beta,\nu\lambda}=0} \tag{6.7.535}$$

Let us recall that implicitly, this relation, named "Bianchi second identity" or "Bianchi differential identity", always expresses simply (if one may say ...) the fact that gravity and geometry of space are linked together.

Following a reader request let us detail much more how to derivative this identity!

The identity is easiest to derive at the origin of a locally inertial frame (LIF) as already mention, where the first derivatives of the metric tensor, and thus the Christoffel symbols, are all zero. At this point, we have:

$$R_{nj\ell m}=\frac{1}{2}\left(\partial_\ell\partial_j g_{mn}+\partial_m\partial_n g_{j\ell}-\partial_\ell\partial_n g_{jm}-\partial_m\partial_j g_{\ell n}\right) \tag{6.7.536}$$

If the Christoffel symbols are all zero, then the covariant derivative becomes the ordinary derivative:

$$\nabla_j A^k\equiv\partial_j A^k+A^i\Gamma_{ij}^k=\partial_j A^k \tag{6.7.537}$$

Therefore, we get, at the origin of a LIF:

$$\begin{aligned}\nabla_k R_{nj\ell m}&=\partial_k R_{nj\ell m}\\&=\frac{1}{2}\left(\partial_k\partial_\ell\partial_j g_{mn}+\partial_k\partial_m\partial_n g_{j\ell}-\partial_k\partial_\ell\partial_n g_{jm}-\partial_k\partial_m\partial_j g_{\ell n}\right)\end{aligned} \tag{6.7.538}$$

By cyclically permuting the index of the derivative with the last two indices of the tensor, we get:

$$\begin{aligned}\nabla_\ell R_{njmk}&=\partial_\ell R_{njmk}\\&=\frac{1}{2}\left(\partial_\ell\partial_m\partial_j g_{kn}+\partial_\ell\partial_k\partial_n g_{jm}-\partial_\ell\partial_m\partial_n g_{jk}-\partial_\ell\partial_k\partial_j g_{mn}\right)\\\nabla_m R_{njk\ell}&=\partial_m R_{njk\ell}\\&=\frac{1}{2}\left(\partial_m\partial_k\partial_j g_{\ell n}+\partial_m\partial_\ell\partial_n g_{jk}-\partial_m\partial_k\partial_n g_{j\ell}-\partial_m\partial_\ell\partial_j g_{kn}\right)\end{aligned} \tag{6.7.539}$$

By adding up all terms with the covariant derivative and using the commutativity of partial derivatives, we see that all terms cancel in pairs, so we get:

$$\nabla_k R_{nj\ell m}+\nabla_\ell R_{njmk}+\nabla_m R_{njk\ell}=0 \tag{6.7.540}$$

As usual we can use the argument that since we can set up a LIF with its origin at any non-singular point in space-time, this equation is true everywhere and since the covariant derivative is a tensor, this is a tensor equation and is thus valid in all coordinate systems.

6.7.13 Ricci curvature (Ricci tensor)

Before we can see the consequences of second Bianchi's identity, we need to define the "Ricci tensor":

$$R_{\alpha\beta}=R_{\alpha\mu\beta}^{\mu} \tag{6.7.541}$$

which is therefore simply the contraction of the first and third indices of the Riemann-Christoffel tensor which we have given above:

$$R^l_{i,jk}=\partial_j\Gamma^l_{ik}-\partial_k\Gamma^l_{ij}+\Gamma^r_{ik}\Gamma^l_{jr}-\Gamma^r_{ij}\Gamma^l_{kr} \tag{6.7.542}$$

in other words it is just a more condensed notation ... and then the letters for the upper or lower indices as well as the presence of the comma are at the free choice of the writer (according to the mood and especially if the context makes it possible to avoid any confusion).

For example with the Riemann-Christoffel tensor we have just given, the Ricci tensor could be written in the following two ways (we keep the indices with latin letters):

$$\begin{gathered}R_{ik}=R^l_{i,jk}\\R_{ik}=R^l_{ijk}\end{gathered} \tag{6.7.543}$$

The Ricci tensor can be taken as the trace of the Riemann tensor, hence it is of lower rank, and has fewer components. If you have a small geodesic ball in free fall, then (ignoring shear and vorticity) the Ricci tensor tells you the rate at which the volume of that ball begins to change, whereas the Riemann tensor contains information not only about its volume, but also about its shape.

Other contractions of other indices may also be possible but because $R_{\alpha\beta,\mu\nu}$ is antisymmetric on α,β and μ,ν then the contraction on these indices are equivalent to have $\pm R_{\alpha\beta}$.

Remark

There is no widely accepted convention for the sign of the Riemann curvature tensor, or the Ricci tensor, so check the sign conventions of whatever book you are reading!

Similarly, we define the "Ricci scalar" (also sometimes named "Riemann scalar") by the relation:

$$\boxed{R=g^{\alpha\beta}R_{\alpha\beta}=g^{\alpha\beta}g^{\mu\upsilon}R_{\mu\alpha\upsilon\beta}} \tag{6.7.544}$$

which has the following properties:

- If the space is flat, the Ricci scalar is zero
- If space is curved like a sphere, the Ricci scalar is positive
- If the space is curved like a horse saddle, the Ricci scalar is negative

Remark

It is not necessarily obvious at first sight without computing the Ricci scalar to know whether a given metric is curved of flat. We can take a perfectly flat space-time and express it in some bizarre coordinate system, in which the metric has non-constant off-diagonal terms!

Either explicitly (by changing the notation for the indices in order to insist on the fact that it has no impact!):

$$\begin{aligned} R=g^{ij}R_{ij}=g^{ij}R^{\mu}_{i,\mu j}&=g^{ij}\left(\partial_\mu\Gamma^{\mu}_{ij}-\partial_j\Gamma^{\mu}_{i\mu}+\Gamma^{r}_{ij}\Gamma^{\mu}_{\mu\sigma}-\Gamma^{r}_{i\mu}\Gamma^{\mu}_{jr}\right)\\ &=g^{ij}\begin{pmatrix}\partial_\mu\left(\dfrac{1}{2}g^{\mu l}(\partial_i g_{lj}+\partial_j g_{il}-\partial_l g_{ij})\right)-\partial_j\left(\dfrac{1}{2}g^{\mu l}(\partial_i g_{l\mu}+\partial_\mu g_{il}-\partial_l g_{i\mu})\right)\\ +\left(\dfrac{1}{2}g^{rl}(\partial_i g_{lj}+\partial_j g_{il}-\partial_l g_{ij})\right)\left(\dfrac{1}{2}g^{\mu l}(\partial_\mu g_{lr}+\partial_r g_{\mu l}-\partial_l g_{\mu r})\right)\\ -\left(\dfrac{1}{2}g^{rl}(\partial_i g_{l\mu}+\partial_\mu g_{il}-\partial_l g_{i\mu})\right)\left(\dfrac{1}{2}g^{\mu l}(\partial_j g_{lr}+\partial_r g_{jl}-\partial_l g_{jr})\right)\end{pmatrix}\end{aligned} \tag{6.7.545}$$

The Ricci scalar is the trace of the Ricci tensor, and it is a measure of scalar curvature. It can be taken as a way to quantify how the volume of a small geodesic ball (or alternatively its surface area) is different from that of a reference ball in flat space.

We will have concrete practical examples in the section of General Relativity for the first two cases, but let us look at simplified examples for the first two cases (we will not, however, prove the reciprocal).

✍**Examples:**

E1. Let us start with the metric of flat space (without the temporal component). We have (see section General Relativity page 5731):

$$g_{ij}=\begin{bmatrix}1&0&0\\0&1&0\\0&0&1\end{bmatrix} \tag{6.7.546}$$

By taking the definition of Ricci's scalar in explicit form:

$$R=g^{ij}\begin{pmatrix}\partial_\mu\left(\dfrac{1}{2}g^{\mu l}(\partial_i g_{lj}+\partial_j g_{il}-\partial_l g_{ij})\right)-\partial_j\left(\dfrac{1}{2}g^{\mu l}(\partial_i g_{l\mu}+\partial_\mu g_{il}-\partial_l g_{i\mu})\right)\\ +\left(\dfrac{1}{2}g^{rl}(\partial_i g_{lj}+\partial_j g_{il}-\partial_l g_{ij})\right)\left(\dfrac{1}{2}g^{\mu l}(\partial_\mu g_{lr}+\partial_r g_{\mu l}-\partial_l g_{\mu r})\right)\\ -\left(\dfrac{1}{2}g^{rl}(\partial_i g_{l\mu}+\partial_\mu g_{il}-\partial_l g_{i\mu})\right)\left(\dfrac{1}{2}g^{\mu l}(\partial_j g_{lr}+\partial_r g_{jl}-\partial_l g_{jr})\right)\end{pmatrix} \tag{6.7.547}$$

It is immediate that R is zero since the partial derivatives will all be zero. So a flat space has a null Ricci scalar.

E2. Let us now look at the metric of the plane expressed in spherical coordinates (without the temporal component). We have (see section General Relativity page 5732):

$$g_{ij}=\begin{bmatrix}1&0&0\\0&r^2&0\\0&0&r^2\sin^2(\theta)\end{bmatrix} \tag{6.7.548}$$

and:

$$g^{ij}=\begin{bmatrix}1 & 0 & 0\\ 0 & \dfrac{1}{r^2} & 0\\ 0 & 0 & \dfrac{r^2}{\sin^2(\theta)}\end{bmatrix} \tag{6.7.549}$$

with:

$$\mathrm{d}s^2=\mathrm{d}r^2+r^2\mathrm{d}\theta^2+r^2\sin^2(\theta)\mathrm{d}\phi^2 \tag{6.7.550}$$

We know that to compute the Ricci scalar (or Ricci curvature), we must therefore compute the contraction of the Riemann-Christoffel tensor (that is, the Ricci tensor) which itself depends on the Christoffel symbols of the second kind which themselves depend on the symbols of Christoffel of the first kind (argh!). We should therefore begin with the lowest level, that is to say by determining all the Christoffel symbols of the first kind given for recall by:

$$\Gamma_{kji}=\frac{1}{2}(\partial_k g_{ij}+\partial_i g_{jk}-\partial_j g_{ki}) \tag{6.7.551}$$

So we have 3^3 that is 27 possible Christoffel symbols of the first kind! Even if some symbols are equal (we have proved it!), We will still calculate everything.

Let's start with joy and good humour...:

$$\begin{aligned}
\Gamma_{111} &= \frac{1}{2}\left(\partial_1 g_{11} + \partial_1 g_{11} - \partial_1 g_{11}\right) = \frac{1}{2}\partial_1 g_{11} = 0\\
\Gamma_{112} &= \frac{1}{2}\left(\partial_1 g_{21} + \partial_2 g_{11} - \partial_1 g_{12}\right) = \frac{1}{2}\partial_2 g_{11} = 0\\
\Gamma_{113} &= \frac{1}{2}\left(\partial_1 g_{31} + \partial_3 g_{11} - \partial_1 g_{13}\right) = \frac{1}{2}\partial_3 g_{11} = 0\\[1em]
\Gamma_{121} &= \frac{1}{2}\left(\partial_1 g_{12} + \partial_1 g_{21} - \partial_2 g_{11}\right) = -\frac{1}{2}\partial_2 g_{11} = 0\\
\Gamma_{122} &= \frac{1}{2}\left(\partial_1 g_{22} + \partial_2 g_{21} - \partial_2 g_{12}\right) = \frac{1}{2}\partial_1 g_{22} = r\\
\Gamma_{123} &= \frac{1}{2}\left(\partial_1 g_{32} + \partial_3 g_{21} - \partial_2 g_{13}\right) = 0\\[1em]
\Gamma_{131} &= \frac{1}{2}\left(\partial_1 g_{13} + \partial_1 g_{31} - \partial_3 g_{11}\right) = -\frac{1}{2}\partial_3 g_{11} = 0\\
\Gamma_{132} &= \frac{1}{2}\left(\partial_1 g_{23} + \partial_2 g_{31} - \partial_3 g_{12}\right) = 0\\
\Gamma_{133} &= \frac{1}{2}\left(\partial_1 g_{33} + \partial_3 g_{31} - \partial_3 g_{13}\right) = \frac{1}{2}\partial_1 g_{33} = r\sin^2(\theta)\\[1em]
\Gamma_{211} &= \frac{1}{2}\left(\partial_2 g_{11} + \partial_1 g_{12} - \partial_1 g_{21}\right) = \frac{1}{2}\partial_2 g_{11} = 0\\
\Gamma_{212} &= \frac{1}{2}\left(\partial_2 g_{21} + \partial_2 g_{12} - \partial_1 g_{22}\right) = -\frac{1}{2}\partial_1 g_{22} = -r\\
\Gamma_{213} &= \frac{1}{2}\left(\partial_2 g_{13} + \partial_3 g_{12} - \partial_1 g_{23}\right) = 0\\[1em]
\Gamma_{221} &= \frac{1}{2}\left(\partial_2 g_{12} + \partial_1 g_{22} - \partial_2 g_{21}\right) = \frac{1}{2}\partial_1 g_{22} = r\\
\Gamma_{222} &= \frac{1}{2}\left(\partial_2 g_{22} + \partial_2 g_{22} - \partial_2 g_{22}\right) = \frac{1}{2}\partial_2 g_{22} = 0\\
\Gamma_{223} &= \frac{1}{2}\left(\partial_2 g_{32} + \partial_3 g_{22} - \partial_2 g_{23}\right) = \frac{1}{2}\partial_3 g_{22} = 0\\[1em]
\Gamma_{231} &= \frac{1}{2}\left(\partial_2 g_{13} + \partial_1 g_{32} - \partial_3 g_{21}\right) = 0\\
\Gamma_{232} &= \frac{1}{2}\left(\partial_2 g_{23} + \partial_2 g_{32} - \partial_3 g_{22}\right) = -\frac{1}{2}\partial_3 g_{22} = 0\\
\Gamma_{233} &= \frac{1}{2}\left(\partial_2 g_{33} + \partial_3 g_{32} - \partial_3 g_{23}\right) = \frac{1}{2}\partial_2 g_{33} = r^2\sin(\theta)\cos(\theta)
\end{aligned}\tag{6.7.552}$$

$$\begin{aligned}
\Gamma_{311} &= \frac{1}{2}\left(\partial_3 g_{11}+\partial_1 g_{13}-\partial_1 g_{31}\right)=\frac{1}{2}\partial_3 g_{11}=0\\
\Gamma_{312} &= \frac{1}{2}\left(\partial_3 g_{21}+\partial_2 g_{13}-\partial_1 g_{32}\right)=0\\
\Gamma_{313} &= \frac{1}{2}\left(\partial_3 g_{31}+\partial_3 g_{13}-\partial_1 g_{33}\right)=-\frac{1}{2}\partial_1 g_{33}=-r\sin^2(\theta)\\
\\
\Gamma_{321} &= \frac{1}{2}\left(\partial_3 g_{12}+\partial_1 g_{23}-\partial_2 g_{31}\right)=0\\
\Gamma_{322} &= \frac{1}{2}\left(\partial_3 g_{22}+\partial_2 g_{23}-\partial_2 g_{32}\right)=\frac{1}{2}\partial_3 g_{22}=0\\
\Gamma_{323} &= \frac{1}{2}\left(\partial_3 g_{32}+\partial_3 g_{23}-\partial_2 g_{33}\right)=-\frac{1}{2}\partial_2 g_{33}=-r^2\sin(\theta)\cos(\theta)\\
\\
\Gamma_{331} &= \frac{1}{2}\left(\partial_3 g_{13}+\partial_1 g_{33}-\partial_3 g_{31}\right)=\frac{1}{2}\partial_1 g_{33}=r\sin^2(\theta)\\
\Gamma_{332} &= \frac{1}{2}\left(\partial_3 g_{23}+\partial_2 g_{33}-\partial_3 g_{32}\right)=\frac{1}{2}\partial_2 g_{33}=r^2\sin(\theta)\cos(\theta)\\
\Gamma_{333} &= \frac{1}{2}\left(\partial_3 g_{33}+\partial_3 g_{33}-\partial_3 g_{33}\right)=\frac{1}{2}\partial_3 g_{33}=0
\end{aligned} \tag{6.7.553}$$

Let us now calculate all the symbols of Christoffel symbols of the second in the details:

$$\Gamma_{kj}^{i}=g^{il}\Gamma_{klj}=\frac{1}{2}g^{il}\left(\partial_k g_{lj}+\partial_j g_{kl}-\partial_l g_{kj}\right) \tag{6.7.554}$$

Again, as the metric tensor is diagonal, this will simplify the calculations!

We have then:

$$\begin{aligned}
\Gamma_{12}^{2} &= g^{22}\Gamma_{122}=\frac{1}{r^2}\cdot r=\frac{1}{r}\\
\Gamma_{13}^{3} &= g^{33}\Gamma_{133}=\frac{1}{r^2\sin^2(\theta)}\cdot r\sin^2(\theta)=\frac{1}{r}\\
\Gamma_{22}^{1} &= g^{11}\Gamma_{212}=1\cdot(-r)=-r\\
\Gamma_{21}^{2} &= g^{22}\Gamma_{221}=\frac{1}{r^2}\cdot r=\frac{1}{r}\\
\Gamma_{23}^{3} &= g^{33}\Gamma_{233}=\frac{1}{r^2\sin^2(\theta)}\cdot r^2\sin(\theta)\cos(\theta)=\frac{\cos(\theta)}{\sin(\theta)}=\frac{1}{\tan(\theta)}=\cot(\theta)\\
\Gamma_{33}^{1} &= g^{11}\Gamma_{313}=1\cdot(-r\sin^2(\theta))=-r\sin^2(\theta)\\
\Gamma_{33}^{2} &= g^{22}\Gamma_{323}=\frac{1}{r^2}\cdot(-r^2\sin(\theta)\cos(\theta))=-\sin(\theta)\cos(\theta)\\
\Gamma_{31}^{3} &= g^{33}\Gamma_{331}=\frac{1}{r^2\sin^2(\theta)}\cdot r\sin^2(\theta)=\frac{1}{r}\\
\Gamma_{32}^{3} &= g^{33}\Gamma_{332}=\frac{1}{r^2\sin^2(\theta)}\cdot r^2\sin(\theta)\cos(\theta)=\frac{\cos(\theta)}{\sin(\theta)}=\frac{1}{\tan(\theta)}=\cot(\theta)
\end{aligned} \tag{6.7.555}$$

Let us now calculate the 9 components of the Ricci tensor in details according to:

$$R_{\alpha\beta}=R_{\alpha\mu\beta}^{\mu}=\partial_\mu\Gamma_{\alpha\beta}^{\mu}-\partial_\beta\Gamma_{\alpha\beta}^{\mu}+\Gamma_{\alpha\beta}^{r}\Gamma_{\mu\sigma}^{\mu}-\Gamma_{\alpha\mu}^{r}\Gamma_{\beta r}^{\mu} \tag{6.7.556}$$

We then have (we calculate them all, even if we know that subsequently those which do not have $\alpha=\beta$ will be useless by the fact that the metric is diagonal):

$$\begin{aligned}
R_{11}=R^{\mu}_{1\mu 1}&=\partial_{\mu}\Gamma^{\mu}_{11}-\partial_1\Gamma^{\mu}_{1\mu}+\Gamma^{r}_{11}\Gamma^{\mu}_{\mu\sigma}-\Gamma^{r}_{1\mu}\Gamma^{\mu}_{1r}=-\partial_1\Gamma^{\mu}_{1\mu}-\Gamma^{r}_{1\mu}\Gamma^{\mu}_{1r}\\
&=-\left(\partial_1\Gamma^{1}_{11}+\partial_1\Gamma^{2}_{12}+\partial_1\Gamma^{3}_{13}\right)-\left(\Gamma^{r}_{11}\Gamma^{1}_{1r}+\Gamma^{r}_{12}\Gamma^{2}_{1r}+\Gamma^{r}_{13}\Gamma^{3}_{1r}\right)\\
&=-\left(\partial_1\Gamma^{2}_{12}+\partial_1\Gamma^{3}_{13}\right)-\left(\Gamma^{r}_{12}\Gamma^{2}_{1r}+\Gamma^{r}_{13}\Gamma^{3}_{1r}\right)\\
&=-\left(\partial_1\Gamma^{2}_{12}+\partial_1\Gamma^{3}_{13}\right)-\left((\Gamma^{1}_{12}\Gamma^{2}_{11}+\Gamma^{2}_{12}\Gamma^{2}_{12}+\Gamma^{3}_{12}\Gamma^{2}_{13})+\Gamma^{r}_{13}\Gamma^{3}_{1r}\right)\\
&=-\left(\partial_1\Gamma^{2}_{12}+\partial_1\Gamma^{3}_{13}\right)-\left((\Gamma^{2}_{12}\Gamma^{2}_{12})+\Gamma^{r}_{13}\Gamma^{3}_{1r}\right)\\
&=-\left(\partial_1\Gamma^{2}_{12}+\partial_1\Gamma^{3}_{13}\right)-\left(\Gamma^{2}_{12}\Gamma^{2}_{12}+(\Gamma^{1}_{13}\Gamma^{3}_{11}+\Gamma^{2}_{13}\Gamma^{3}_{12}+\Gamma^{3}_{13}\Gamma^{3}_{13})\right)\\
&=-\left(\partial_1\Gamma^{2}_{12}+\partial_1\Gamma^{3}_{13}\right)-\left(\Gamma^{2}_{12}\Gamma^{2}_{12}+\Gamma^{3}_{13}\Gamma^{3}_{13}\right)=-\left(\partial_r\frac{1}{r}+\partial_r\frac{1}{r}\right)-\left(\frac{1}{r}\frac{1}{r}+\frac{1}{r}\frac{1}{r}\right)\\
&=-\left(-\frac{1}{r^2}-\frac{1}{r^2}\right)-\frac{2}{r^2}=\frac{2}{r^2}-\frac{2}{r^2}=0
\end{aligned}$$

$$\begin{aligned}
R_{12}=R^{\mu}_{1\mu 2}&=\partial_{\mu}\Gamma^{\mu}_{12}-\partial_2\Gamma^{\mu}_{1\mu}+\Gamma^{r}_{12}\Gamma^{\mu}_{\mu r}-\Gamma^{r}_{1\mu}\Gamma^{\mu}_{2r}\\
&=\left(\partial_1\Gamma^{1}_{12}-\partial_2\Gamma^{1}_{11}+\Gamma^{r}_{12}\Gamma^{1}_{1r}-\Gamma^{r}_{11}\Gamma^{1}_{2r}\right)+\left(\partial_2\Gamma^{2}_{12}-\partial_2\Gamma^{2}_{12}+\Gamma^{r}_{12}\Gamma^{2}_{2r}-\Gamma^{r}_{12}\Gamma^{2}_{2r}\right)\\
&+\left(\partial_3\Gamma^{3}_{12}-\partial_2\Gamma^{3}_{13}+\Gamma^{r}_{12}\Gamma^{3}_{3r}-\Gamma^{r}_{13}\Gamma^{3}_{2r}\right)=\left(-\partial_2\Gamma^{3}_{13}+\Gamma^{r}_{12}\Gamma^{3}_{3r}-\Gamma^{r}_{13}\Gamma^{3}_{2r}\right)\\
&=\left(-\partial_2\Gamma^{3}_{13}+\left(\Gamma^{1}_{12}\Gamma^{3}_{31}+\Gamma^{2}_{12}\Gamma^{3}_{32}+\Gamma^{3}_{12}\Gamma^{3}_{33}\right)-\Gamma^{r}_{13}\Gamma^{3}_{2r}\right)\\
&=\left(-\partial_2\Gamma^{3}_{13}+\left(\Gamma^{2}_{12}\Gamma^{3}_{32}\right)-\Gamma^{r}_{13}\Gamma^{3}_{2r}\right)=\left(-\partial_2\Gamma^{3}_{13}+\left(\Gamma^{2}_{12}\Gamma^{3}_{32}\right)-\left(\Gamma^{1}_{13}\Gamma^{3}_{21}+\Gamma^{2}_{13}\Gamma^{3}_{22}+\Gamma^{3}_{13}\Gamma^{3}_{23}\right)\right)\\
&=\left(-\partial_2\Gamma^{3}_{13}+\left(\Gamma^{2}_{12}\Gamma^{3}_{32}\right)-\left(\Gamma^{3}_{13}\Gamma^{3}_{23}\right)\right)=-\partial_2\Gamma^{3}_{13}+\Gamma^{2}_{12}\Gamma^{3}_{32}-\Gamma^{3}_{13}\Gamma^{3}_{23}\\
&=-\partial_{\theta}\frac{1}{r}+\frac{1}{r}\cot(\theta)-\frac{1}{r}\cot(\theta)=0
\end{aligned}\qquad(6.7.557)$$

$$\begin{aligned}
R_{13} &= R^{\mu}_{1\mu 3} = \partial_{\mu}\Gamma^{\mu}_{13} - \partial_3\Gamma^{\mu}_{1\mu} + \Gamma^{r}_{13}\Gamma^{\mu}_{\mu r} - \Gamma^{r}_{1\mu}\Gamma^{\mu}_{3r}\\
&= \left(\partial_1\Gamma^{1}_{13} - \partial_3\Gamma^{1}_{11} + \Gamma^{r}_{13}\Gamma^{1}_{1r} - \Gamma^{r}_{11}\Gamma^{1}_{3r}\right) + \left(\partial_2\Gamma^{2}_{13} - \partial_3\Gamma^{2}_{12} + \Gamma^{r}_{13}\Gamma^{2}_{2r} - \Gamma^{r}_{12}\Gamma^{2}_{3r}\right)\\

&=-\left(-\sin^2(\theta)+\cos^2(\theta)\right)-\sin^2(\theta)+\frac{\cos(\theta)}{\sin(\theta)}\sin(\theta)\cos(\theta)\\
&=\left(\sin^2(\theta)-\cos^2(\theta)\right)-\sin^2(\theta)+\cos^2(\theta)=0
\end{aligned}
\tag{6.7.561}
$$

Let us now calculate the Ricci scalar:

$$R=g^{\alpha\beta}R_{\alpha\beta}\tag{6.7.562}$$

we then have:

$$
\begin{aligned}
R=g^{\alpha\beta}R_{\alpha\beta}&=g^{11}R_{11}+g^{22}R_{22}+g^{33}R_{33}\\
&=1\cdot R_{11}+\frac{1}{r^2}R_{22}+\frac{1}{r^2\sin^2(\theta)}R_{33}\\
&=1\cdot 0+\frac{1}{r^2}\cdot 0+\frac{1}{r^2\sin^2(\theta)}\cdot 0=0
\end{aligned}
\tag{6.7.563}
$$

The Ricci scalar is therefore also zero. This result may be surprising, but in reality it is logical since we have only calculated the scalar curvature of a flat space expressed in spherical coordinates.

E3. Let us now impose ourselves the diagonal metric of the 2-sphere surface $\mathcal{S}^2$ (without the temporal component). We have then in agreement with what we have seen in the section of Differential Geometry page 2884:

$$g_{ij}=\begin{bmatrix} r^2 & 0\\ 0 & r^2\sin^2(\theta)\end{bmatrix}\tag{6.7.564}$$

and:

$$g^{ij}=\begin{bmatrix}\dfrac{1}{r^2} & 0\\ 0 & \dfrac{1}{r^2\sin^2(\theta)}\end{bmatrix} \tag{6.7.565}$$

Therefore (see section Differential Geometry page 2884):

$$\mathrm{d}s^2=r^2\mathrm{d}\theta^2+r^2\sin^2(\theta)\mathrm{d}\phi^2 \tag{6.7.566}$$

often written as:

$$\mathrm{d}s^2=r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right)=r^2\mathrm{d}\Omega^2 \tag{6.7.567}$$

where r is a constant!

We shall therefore begin with the lowest level, that is, by determining all the Christoffel symbols of the first kind given for recall by:

$$\Gamma_{kji}=\frac{1}{2}\left(\partial_k g_{ij}+\partial_i g_{jk}-\partial_j g_{ki}\right) \tag{6.7.568}$$

We have therefore 2^3, that is, 8 possible Christoffel symbols of the first kind! Even if some symbols are equal (we have already proved it!), we will still calculate everything:

$$\begin{aligned}
\Gamma_{111}&=\frac{1}{2}\left(\partial_1 g_{11}+\partial_1 g_{11}-\partial_1 g_{11}\right)=\frac{1}{2}\partial_1 g_{11}=0\\
\Gamma_{112}&=\frac{1}{2}\left(\partial_1 g_{21}+\partial_2 g_{11}-\partial_1 g_{12}\right)=\frac{1}{2}\partial_2 g_{11}=0\\
\\
\Gamma_{121}&=\frac{1}{2}\left(\partial_1 g_{12}+\partial_1 g_{21}-\partial_2 g_{11}\right)=-\frac{1}{2}\partial_2 g_{11}=0\\
\Gamma_{122}&=\frac{1}{2}\left(\partial_1 g_{22}+\partial_2 g_{21}-\partial_2 g_{12}\right)=\frac{1}{2}\partial_1 g_{22}=r^2\sin(\theta)\cos(\theta)\\
\\
\Gamma_{211}&=\frac{1}{2}\left(\partial_2 g_{11}+\partial_1 g_{12}-\partial_1 g_{21}\right)=\frac{1}{2}\partial_2 g_{11}=0\\
\Gamma_{212}&=\frac{1}{2}\left(\partial_2 g_{21}+\partial_2 g_{12}-\partial_1 g_{22}\right)=-\frac{1}{2}\partial_1 g_{22}=-r^2\sin(\theta)\cos(\theta)
\end{aligned} \tag{6.7.569}$$

$$\begin{aligned}
\Gamma_{221}&=\frac{1}{2}\left(\partial_2 g_{12}+\partial_1 g_{22}-\partial_2 g_{21}\right)=\frac{1}{2}\partial_1 g_{22}=r^2\sin(\theta)\cos(\theta)\\
\Gamma_{222}&=\frac{1}{2}\left(\partial_2 g_{22}+\partial_2 g_{22}-\partial_2 g_{22}\right)=\frac{1}{2}\partial_2 g_{22}=0
\end{aligned} \tag{6.7.570}$$

Let us now calculate all the Christoffel symbols of the second kind in the details:

$$\Gamma_{kj}^{i}=g^{il}\Gamma_{klj}=\frac{1}{2}g^{il}\left(\partial_k g_{lj}+\partial_j g_{kl}-\partial_l g_{kj}\right) \tag{6.7.571}$$

Again, as the metric tensor is diagonal, this will simplify the calculations!

We have then:

$$\begin{aligned}\Gamma_{12}^{2}&=g^{22}\Gamma_{122}=\frac{1}{r^2\sin^2(\theta)}\cdot r^2\sin(\theta)\cos(\theta)=\cot(\theta)\\ \Gamma_{22}^{1}&=g^{11}\Gamma_{212}=\frac{1}{r^2}\cdot\left(-r^2\sin(\theta)\cos(\theta)\right)=-\sin(\theta)\cos(\theta)\\ \Gamma_{21}^{2}&=g^{22}\Gamma_{221}=\frac{1}{r^2\sin^2(\theta)}\cdot r^2\sin(\theta)\cos(\theta)=\cot(\theta)\end{aligned}\tag{6.7.572}$$

Let us now calculate the 4 components of the Ricci tensor in the details according to:

$$R_{\alpha\beta}=R_{\alpha\mu\beta}^{\mu}=\partial_\mu\Gamma_{\alpha\beta}^{\mu}-\partial_\beta\Gamma_{\alpha\mu}^{\mu}+\Gamma_{\alpha\beta}^{r}\Gamma_{\mu r}^{\mu}-\Gamma_{\alpha\mu}^{r}\Gamma_{\beta r}^{\mu}\tag{6.7.573}$$

We then have (we calculate them all, even if we know that subsequently those which do not have $\alpha=\beta$ will be useless by the fact that the metric is diagonal):

$$\begin{aligned}R_{11}&=R_{1\mu 1}^{\mu}=\partial_\mu\Gamma_{11}^{\mu}-\partial_1\Gamma_{1\mu}^{\mu}+\Gamma_{11}^{r}\Gamma_{\mu r}^{\mu}-\Gamma_{1\mu}^{r}\Gamma_{1r}^{\mu}\\ &=\left(\partial_1\Gamma_{11}^{1}-\partial_1\Gamma_{11}^{1}+\Gamma_{11}^{r}\Gamma_{1r}^{1}-\Gamma_{11}^{r}\Gamma_{1r}^{1}\right)+\left(\partial_2\Gamma_{11}^{2}-\partial_1\Gamma_{12}^{2}+\Gamma_{11}^{r}\Gamma_{2r}^{2}-\Gamma_{12}^{r}\Gamma_{1r}^{2}\right)\\ &=\left(\partial_2\Gamma_{11}^{2}-\partial_1\Gamma_{12}^{2}+\Gamma_{11}^{r}\Gamma_{2r}^{2}-\Gamma_{12}^{r}\Gamma_{1r}^{2}\right)=\left(-\partial_1\Gamma_{12}^{2}-\Gamma_{12}^{r}\Gamma_{1r}^{2}\right)\\ &=\left(-\partial_1\Gamma_{12}^{2}-\Gamma_{12}^{1}\Gamma_{11}^{2}-\Gamma_{12}^{2}\Gamma_{12}^{2}\right)=\left(-\partial_1\Gamma_{12}^{2}-\Gamma_{12}^{2}\Gamma_{12}^{2}\right)\\ &=\left(-\left(-1-\cot^2(\theta)\right)\right)-\cot^2(\theta)=1\\ \\ R_{12}&=R_{1\mu 2}^{\mu}=\partial_\mu\Gamma_{12}^{\mu}-\partial_2\Gamma_{1\mu}^{\mu}+\Gamma_{12}^{r}\Gamma_{\mu r}^{\mu}-\Gamma_{1\mu}^{r}\Gamma_{2r}^{\mu}\\ &=\left(\partial_1\Gamma_{12}^{1}-\partial_2\Gamma_{11}^{1}+\Gamma_{12}^{r}\Gamma_{1r}^{1}-\Gamma_{11}^{r}\Gamma_{2r}^{1}\right)+\left(\partial_2\Gamma_{12}^{2}-\partial_2\Gamma_{12}^{2}+\Gamma_{12}^{r}\Gamma_{2r}^{2}-\Gamma_{12}^{r}\Gamma_{2r}^{2}\right)\\ &=\left(\partial_1\Gamma_{12}^{1}-\partial_2\Gamma_{11}^{1}+\Gamma_{12}^{r}\Gamma_{1r}^{1}-\Gamma_{11}^{r}\Gamma_{2r}^{1}\right)=\Gamma_{12}^{r}\Gamma_{1r}^{1}=\Gamma_{12}^{1}\Gamma_{11}^{1}+\Gamma_{12}^{2}\Gamma_{12}^{1}=0\end{aligned}\tag{6.7.574}$$

$$\begin{aligned}
R_{21}&=R^{\mu}_{2\mu 1}=\partial_{\mu}\Gamma^{\mu}_{21}-\partial_1\Gamma^{\mu}_{2\mu}+\Gamma^{r}_{21}\Gamma^{\mu}_{\mu r}-\Gamma^{r}_{2\mu}\Gamma^{\mu}_{1r}\\
&=\left(\partial_1\Gamma^1_{21}-\partial_1\Gamma^1_{21}+\Gamma^r_{21}\Gamma^1_{1r}-\Gamma^r_{21}\Gamma^1_{1r}\right)+\left(\partial_2\Gamma^2_{21}-\partial_1\Gamma^2_{22}+\Gamma^r_{21}\Gamma^2_{2r}-\Gamma^r_{22}\Gamma^2_{1r}\right)\\
&=\partial_2\Gamma^2_{21}-\partial_1\Gamma^2_{22}+\Gamma^r_{21}\Gamma^2_{2r}-\Gamma^r_{22}\Gamma^2_{1r}=\Gamma^r_{21}\Gamma^2_{2r}-\Gamma^r_{22}\Gamma^2_{1r}\\
&=\left(\Gamma^1_{21}\Gamma^2_{21}+\Gamma^2_{21}\Gamma^2_{22}\right)-\left(\Gamma^1_{22}\Gamma^2_{11}+\Gamma^1_{22}\Gamma^2_{12}\right)=0\\
\\
R_{22}&=R^{\mu}_{2\mu 2}=\partial_{\mu}\Gamma^{\mu}_{22}-\partial_2\Gamma^{\mu}_{2\mu}+\Gamma^{r}_{22}\Gamma^{\mu}_{\mu r}-\Gamma^{r}_{2\mu}\Gamma^{\mu}_{2r}\\
&=\left(\partial_1\Gamma^1_{22}-\partial_2\Gamma^1_{21}+\Gamma^r_{22}\Gamma^1_{1r}-\Gamma^r_{21}\Gamma^1_{2r}\right)+\left(\partial_2\Gamma^2_{22}-\partial_2\Gamma^2_{22}+\Gamma^r_{22}\Gamma^2_{2r}-\Gamma^r_{22}\Gamma^2_{2r}\right)\\
&=\left(\partial_1\Gamma^1_{22}-\partial_2\Gamma^1_{21}+\Gamma^r_{22}\Gamma^1_{1r}-\Gamma^r_{21}\Gamma^1_{2r}\right)\\
&=\left(\partial_1\Gamma^1_{22}+\Gamma^r_{22}\Gamma^1_{1r}-\Gamma^r_{21}\Gamma^1_{2r}\right)=\left(\partial_1\Gamma^1_{22}+\Gamma^1_{22}\Gamma^1_{11}+\Gamma^2_{22}\Gamma^1_{12}-\Gamma^1_{21}\Gamma^1_{21}-\Gamma^2_{21}\Gamma^1_{22}\right)\\
&=\left(\partial_1\Gamma^1_{22}-\Gamma^2_{21}\Gamma^1_{22}\right)=\left(\sin^2(\theta)-\cos^2(\theta)\right)-\cot(\theta)\cdot\left(-\sin(\theta)\cos(\theta)\right)\\
&=\sin^2(\theta)-\cos^2(\theta)+\cot(\theta)\sin(\theta)\cos(\theta)=\sin^2(\theta)-\cos^2(\theta)+\cos(\theta)\cos(\theta)=\sin^2(\theta)
\end{aligned}\tag{6.7.575}$$

Let us now calculate the Ricci scalar:

$$R=g^{\alpha\beta}R_{\alpha\beta}\tag{6.7.576}$$

Remark

Notice that $R_{\alpha\beta}=1/r^2g^{\alpha\beta}$ and for information we can also prove that (its aesthetics but so far it has no practical application in this textbook):

$$R^{\alpha}_{\mu\beta\nu}=\frac{\delta^{\alpha}_{\beta}g_{\mu\nu}-\delta^{\alpha}_{\nu}g_{\mu\beta}}{r^2}\tag{6.7.577}$$

We then have:

$$\begin{aligned}
R&=g^{\alpha\beta}R_{\alpha\beta}=g^{11}R_{11}+g^{22}R_{22}=\frac{1}{r^2}\cdot R_{11}+\frac{1}{r^2\sin^2(\theta)}R_{22}\\
&=\frac{1}{r^2}\cdot 1+\frac{1}{r^2\sin^2(\theta)}\cdot\sin^2(\theta)=\frac{1}{r^2}+\frac{1}{r^2}=\frac{2}{r^2}
\end{aligned}\tag{6.7.578}$$

We notice that:

1. The Ricci scalar is a constant. This means that the hyper-surface has a constant curvature at all points of the surface (we know that the sphere by symmetry has a constant curvature at all points). It thus possesses a form of symmetry, with respect to its curvature. We are then dealing with a "maximally symmetrical variety".

2. This scalar is positive which describes a domed space (ball, sphere) and if $r\rightarrow+\infty$ the curvature is zero!

Remark

Be careful not to confuse the value of the Ricci curvature with that of the Gauss curvature!!!

6.7.14 Einstein Tensor

Let us apply a contraction to the second Bianchi identity (valid for recall with the "+" only if the metric is positive):

$$g^{\alpha\beta}\left(\nabla_\lambda R_{\alpha\beta,\mu\nu}+\nabla_\nu R_{\alpha\beta,\lambda\mu}+\nabla_\mu R_{\alpha\beta,\nu\lambda}\right)=0 \tag{6.7.579}$$

Let us recall that $\nabla_\lambda g_{\alpha\mu}=0$ and similarly by extension that $\Delta_\lambda g^{\alpha\mu}=0$. So finally this leads us to write by the property of the derivatives (product in sum):

$$\nabla_\lambda g^{\alpha\mu}R_{\alpha\beta,\mu\nu}+\nabla_\nu g^{\alpha\mu}R_{\alpha\beta,\lambda\mu}+\nabla_\mu g^{\alpha\beta}R_{\alpha\mu,\nu\lambda}=0 \tag{6.7.580}$$

and therefore to get:

$$\nabla_\lambda R^{\mu}_{\beta,\mu\nu}+\nabla_\nu R^{\mu}_{\beta,\lambda\mu}+\nabla_\mu R^{\mu}_{\beta,\nu\lambda}=0 \tag{6.7.581}$$

Using the antisymmetry property of the Riemann-Christoffel tensor we write:

$$\nabla_\lambda R^{\mu}_{\beta,\mu\nu}-\nabla_\nu R^{\mu}_{\beta,\mu\lambda}+\nabla_\mu R^{\mu}_{\beta,\nu\lambda}=\nabla_\lambda R_{\beta\nu}-\nabla_\nu R^{\mu}_{\beta,\mu\lambda}+\nabla_\mu R^{\mu}_{\beta,\nu\lambda}=0 \tag{6.7.582}$$

What ultimately brings us to write from the definition of Ricci's tensor:

$$\nabla_\lambda R_{\beta\nu}-\nabla_\nu R_{\beta\lambda}+\nabla_\mu R^{\mu}_{\beta,\nu\lambda}=0 \tag{6.7.583}$$

This last relationship being named "contracted Bianchi identity".

Let us contract this relation once more:

$$\begin{aligned}g^{\beta\nu}\left(\nabla_\lambda R_{\beta\nu}-\nabla_\nu R_{\beta\lambda}+\nabla_\mu R^{\mu}_{\beta,\nu\lambda}\right)&=\nabla_\lambda R^{\nu}_{\nu}-\nabla_\nu R^{\nu}_{\lambda}+\nabla_\mu R^{\mu\nu}_{\nu\lambda}=\nabla_\lambda R^{\nu}_{\nu}-\nabla_\nu R^{\nu}_{\lambda}-\nabla_\mu R^{\mu\nu}_{\lambda\nu}\\&=\nabla_\lambda R-\nabla_\nu R^{\nu}_{\lambda}-\nabla_\mu R^{\mu}_{\lambda}=0\end{aligned} \tag{6.7.584}$$

That which is identical to write using the properties of the Einstein summation (which allows to freely change the indices):

$$\nabla_\lambda R-\nabla_\mu R^{\mu}_{\lambda}-\nabla_\mu R^{\mu}_{\lambda}=\nabla_\lambda R-2\nabla_\mu R^{\mu}_{\lambda}=0 \tag{6.7.585}$$

Which is equivalent to:

$$\nabla_\mu R^{\mu}_{\lambda}-\frac{1}{2}\nabla_\lambda R=0 \tag{6.7.586}$$

As $\nabla_\lambda=g^{\mu}_{\lambda}\nabla_\mu R$, we have:

$$\nabla_\mu\left(R^{\mu}_{\lambda}-\frac{1}{2}g^{\mu}_{\lambda}R\right)=0 \tag{6.7.587}$$

By raising the index λ by multiplication with $g^{\nu\mu}$, we get the "Einstein's identity":

$$\nabla_{\mu}\left(R^{\mu\nu}-\frac{1}{2}g^{\mu\nu}R\right)=0 \tag{6.7.588}$$

The "Einstein tensor" (tensor of order two and contravariant in the present case) which is therefore a constant in a given Riemannian space is therefore defined by:

$$\boxed{G^{\mu\nu}=R^{\mu\nu}-\frac{1}{2}g^{\mu\nu}R} \tag{6.7.589}$$

And expresses in the shortest possible way, parallel transport under all assumptions seen so far.

Identically, we can get the covariant form:

$$\boxed{G_{\mu\nu}=R_{\mu\nu}-\frac{1}{2}g_{\mu\nu}R} \tag{6.7.590}$$

The tensor is therefore constructed for a Riemannian metric only (which nevertheless makes a lot of possible spaces ...), and is automatically non-divergent:

$$\nabla_{\mu}G_{\mu\nu}=0 \tag{6.7.591}$$

It must be remembered, however, that a large part of the latest developments consider a symmetrical metric. This is why some speak of "symmetrical gravitational theory" when we deal with General Relativity.

We shall find this tensor naturally in the section of General Relativity when, by making use of the variational principle, we decompose the action into two terms:

- the action of mass in the gravitational field
- the action of the gravitational field in the absence of mass

By expressing the whole in a Riemannian space we will then get the no less famous Einstein field equations (without further explanations in this section):

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}=\frac{8\pi G}{c^4}T_{\mu\nu} \tag{6.7.592}$$

the details being given in the section of General Relativity.

Remark

As we see, we can very well add a constant term to the expression of Einstein's tensor, without changing the nullity of its divergence. This fact, used in Astrophysics, makes it possible to construct models of particular Universes that we will deal with in the section of Cosmology.

✍**Example:**

Let us calculate the order 2 covariant Einstein tensor:

$$G_{\mu\nu}=R_{\mu\nu}-\frac{1}{2}g_{\mu\nu}R \tag{6.7.593}$$

based on the diagonal metric surface of the 2-sphere $\mathcal{S}^2$ (without the temporal component):

$$g_{\mu\nu}=\begin{bmatrix} r^2 & 0 \\ 0 & r^2\sin^2(\theta) \end{bmatrix} \tag{6.7.594}$$

Since the metric is diagonal, we have proved earlier above and in detail by the example that:

$$R_{12}=R_{21}=0 \tag{6.7.595}$$

And as in the present case, we also have:

$$g_{12}=g_{21}=0 \tag{6.7.596}$$

It comes:

$$G_{12}=G_{21}=0 \tag{6.7.597}$$

So we have to focus only on two components:

$$\begin{aligned} G_{11}&=R_{11}-\frac{1}{2}g_{11}R=1-\frac{1}{2}r^2\frac{2}{r^2}=1-\frac{1}{2}r^2\frac{2}{r^2}=0 \\ G_{22}&=R_{22}-\frac{1}{2}g_{22}\frac{2}{r^2}=\sin^2(\theta)-\frac{1}{2}r^2\sin^2(\theta)\frac{2}{r^2}=0 \end{aligned} \tag{6.7.598}$$

which confirms what we have said earlier above.

The complexity of the Einstein Tensor expression can be shown using the formula for the Ricci tensor in terms of Christoffel symbols:

$$\begin{aligned} G_{\alpha\beta}&=R_{\alpha\beta}-\frac{1}{2}g_{\alpha\beta}R \\ &=R_{\alpha\beta}-\frac{1}{2}g_{\alpha\beta}g^{\gamma\zeta}R_{\gamma\zeta} \\ &=(\delta_\alpha^\gamma\delta_\beta^\zeta-\frac{1}{2}g_{\alpha\beta}g^{\gamma\zeta})R_{\gamma\zeta} \\ &=(\delta_\alpha^\gamma\delta_\beta^\zeta-\frac{1}{2}g_{\alpha\beta}g^{\gamma\zeta})(\Gamma^{\varepsilon}_{\gamma\zeta,\varepsilon}-\Gamma^{\varepsilon}_{\gamma\varepsilon,\zeta}+\Gamma^{\varepsilon}_{\varepsilon\sigma}\Gamma^{\sigma}_{\gamma\zeta}-\Gamma^{\varepsilon}_{\zeta\sigma}\Gamma^{\sigma}_{\varepsilon\gamma}), \end{aligned} \tag{6.7.599}$$

where δ_β^α is the Kronecker tensor and the Christoffel symbol ${\Gamma^\alpha}_{\beta\gamma}$ is given for recall by:

$${\Gamma^\alpha}_{\beta\gamma}=\frac{1}{2}g^{\alpha\varepsilon}(g_{\beta\varepsilon,\gamma}+g_{\gamma\varepsilon,\beta}-g_{\beta\gamma,\varepsilon}) \tag{6.7.600}$$

Before cancellations, this formula results in $2\times(6+6+9+9)=60$ individual terms. Cancellations bring this number down somewhat.

6.8. Spinor Calculus

As we will see first in relativistic quantum physics, spinors play a major role in quantum theory, and therefore in all contemporary physics (quantum field theory, standard model, string theory, etc.). The actual purpose of this section on the spinors is only to give the tools to the reader that are necessary to a deep understanding of what will be done in the chapter about Atomistic.

It was starting 11927 (holocene calendar) that the physicists Pauli, and after Dirac introduced spinors for the representation of the wave functions (see section Relativistic Quantum Physics page 4932). However, in their mathematical form, spinors were discovered by Elie Cartan in 11913 (holocene calendar) during his research on the representations of the groups following the general theory of Clifford spaces (introduced by the mathematician W.K. Clifford in 11876 according to holocene calendar). He showed, as we will see it, that in spinors provide in fact a linear representation of the group of rotations of a space with any number of dimensions. Thus, spinors are closely related to geometry but they are often introduce in an abstract way without intuitive geometric meaning. Thus, we will try (as always on this textbook) in this section to introduce this tool in the most simple and intuitive possible way with a maximum of details.

The spinor formalism is not interest only of interest for quantum physics and its related developments, among others, Roger Penrose showed that the spinor theory was an extremely fruitful approach to the theory of General Relativity. Even if the most commonly used tool for the treatment of General Relativity is the tensor calculus, Penrose seems to have shown that in the specific case of the four-dimensional space and in the metric Lorentz the formalism of two components spinors was more appropriate.

The theory of spinors named, "spinor calculus" or sometimes "spin geometry" is extremely broad but as we know this textbook aims to address the physicists and engineers therefore we will limit ourselves to spinors properties useful in quantum physics (at least actually).

Remark

We strongly recommend the reader to have previously read the subsubsection on quaternions (see section Numbers page 261), the subsubsection on rotations in space (see section Euclidean Geometry page 2647) and finally, if possible, for a physical practical example, the section on Relativistic Quantum Physics page 4919.

6.8.1 Unit Spinor

We will give here a first simplified and special definition (or example) of spinors. Thus, we will show that it is possible from such a tool to represent a vector equation of a space E^3 of three components using a two-component spinor. The method is extremely simple and the reader who has already read the part of the section on Quantum Wave Physics dealing with the Dirac equation and the section on Quantum Computing will see a rather beautiful analogy.

Consider to start the sphere of radius of the following equation (see section Analytical Geometry page 2964):

$$x^2+y^2+z^2=1 \tag{6.8.1}$$

And consider the following figure:

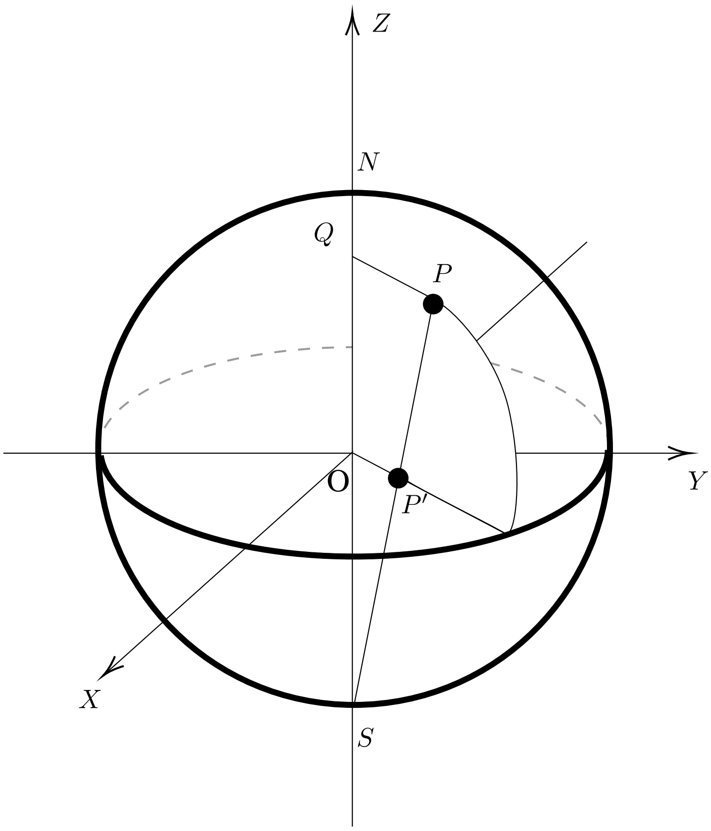

Figure 6.163: **Unit Sphere**

Let us put on this sphere of center on O and unit radius a point P of coordinates (x,y,z) and denote by N (north) and S (south) the points of the sphere intersecting with the Z axis.

The point S will have by convention for coordinates:

$$S=\begin{pmatrix}x\\y\\z\end{pmatrix}=\begin{pmatrix}0\\0\\-1\end{pmatrix} \tag{6.8.2}$$

We obtain a projection so-named "stereographic projection " P' of the point P by tracing the straight line $\overline{SP}$ that passes through the complex equatorial plane $x\text{O}y$ (yes! we chose $\mathbb{C}$ as plane!) at point P' of coordinates (x',y',z').

The similar triangles $SP'\text{O}$ and SPQ (with Q being the orthogonal projection onto the Z-axis of the point P) gives us the following relations by simply applying Thales' theorem (see section Euclidean Geometry page 2610):

$$\triangle SP'\text{O} \sim \triangle SPQ \Leftrightarrow \frac{SP}{SP'} = \frac{x}{x'} = \frac{y}{y'} = \frac{1}{1+z} = \frac{x'+\mathrm{i}y'}{x+\mathrm{i}y} = \frac{x'-\mathrm{i}y}{x-\mathrm{i}y} \tag{6.8.3}$$

Remark

The last two relation (ratios) are obtained by simply applying Thales' theorem (see section Euclidean Geometry) in the complex equatorial plane.

Let us write now to simplify the notations:

$$\xi = x' + \mathrm{i}y' \qquad \bar{\xi} = x' - \mathrm{i}y' \tag{6.8.4}$$

We have from the prior-previous relation that:

$$\frac{1}{1+z} = \frac{x'+\mathrm{i}y'}{x+\mathrm{i}y} \tag{6.8.5}$$

Taking the squared modulus (see the study of complex numbers in the section on Numbers):

$$\frac{1}{|1+z|^2} = \frac{1}{(1+z)^2} = \frac{|x'+\mathrm{i}y'|^2}{|x+\mathrm{i}y|^2} = \frac{\xi\bar{\xi}}{x^2+y^2} \tag{6.8.6}$$

and from the equation of the sphere it follows:

$$x^2+y^2 = 1-z^2 = (1+z)(1-z) \tag{6.8.7}$$

we finally get:

$$\frac{1}{(1+z)^2} = \frac{\xi\bar{\xi}}{x^2+y^2} = \frac{\xi\bar{\xi}}{(1+z)(1-z)} \tag{6.8.8}$$

Let us write now the complex number ξ under the form:

$$\xi = x' + \mathrm{i}y' = \frac{\phi}{\psi} \tag{6.8.9}$$

where ϕ, ψ are two complex numbers that we can always impose verify the following condition of unitarity (nothing prevents us to do that but for theoretical physics purpose this choice suit us well...):

$$\phi\bar{\phi} + \psi\bar{\psi} = 1 \tag{6.8.10}$$

Remark

The following complex numbers satisfy for example (hazard!!??) the above condition:

$$\psi = e^{\mathrm{i}\beta}\cos(\alpha) \qquad \phi = e^{\mathrm{i}\gamma}\sin(\alpha) \tag{6.8.11}$$

Remember before continuing that we have proved in our study of complex numbers (see section Numbers page 247) that:

$$\xi=\frac{\phi}{\psi},\bar{\xi}=\overline{\left(\frac{\phi}{\psi}\right)}=\frac{\bar{\phi}}{\bar{\psi}} \tag{6.8.12}$$

Therefore it comes by injecting the last two relations in the equation given above:

$$\frac{1}{(1+z)^2}=\frac{\dfrac{\phi}{\psi}\dfrac{\bar{\phi}}{\bar{\psi}}}{(1+z)(1-z)} \tag{6.8.13}$$

So we get:

$$\psi\bar{\psi}=\phi\bar{\phi}\frac{1+z}{1-z} \tag{6.8.14}$$

Rearranged:

$$\psi\bar{\psi}(1-z)=\phi\bar{\phi}(1+z) \tag{6.8.15}$$

Therefore:

$$\psi\bar{\psi}-z\psi\bar{\psi}=\phi\bar{\phi}+z\psi\bar{\psi}\Leftrightarrow\psi\bar{\psi}-\phi\bar{\phi}=z\left(\psi\bar{\psi}+\phi\bar{\phi}\right) \tag{6.8.16}$$

Finally we have a simple expression for the z coordinate of the point P because in the last equality above you must remember that $\psi\bar{\psi}+\phi\bar{\phi}=1$ then:

$$z=\psi\bar{\psi}-\phi\bar{\phi} \tag{6.8.17}$$

As we have:

$$x+\mathrm{i}y=\xi(1+z)\quad\text{and}\qquad x-\mathrm{i}y=\bar{\xi}(1+z) \tag{6.8.18}$$

Then by summing and respectively by substracting the two above relations and using previous results we get:

$$\begin{aligned}x&=\frac{1}{2}\left(\xi+\bar{\xi}\right)(1+z)=\frac{1}{2}\left(\frac{\phi}{\psi}+\frac{\bar{\phi}}{\bar{\psi}}\right)((\psi\bar{\psi}+\phi\bar{\phi})+(\psi\bar{\psi}-\phi\bar{\phi}))=\psi\bar{\phi}+\bar{\psi}\phi\\y&=-\frac{\mathrm{i}}{2}\left(\xi-\bar{\xi}\right)(1+z)=\frac{\mathrm{i}}{2}\left(\frac{\phi}{\psi}-\frac{\bar{\phi}}{\bar{\psi}}\right)((\psi\bar{\psi}+\phi\bar{\phi})+(\psi\bar{\psi}-\phi\bar{\phi}))=\mathrm{i}\left(\psi\bar{\phi}-\bar{\psi}\phi\right)\end{aligned} \tag{6.8.19}$$

To resume for the point P we have with our choices:

$$\begin{aligned}x&=\psi\bar{\phi}+\bar{\psi}\phi\\y&=\mathrm{i}\left(\psi\bar{\phi}-\bar{\psi}\phi\right)\\z&=\psi\bar{\psi}-\phi\bar{\phi}\end{aligned} \tag{6.8.20}$$

Thus, for any point P on the sphere of radius unity, we can match a pair of complex numbers satisfying the imposed unitary identity!

Therefore in complete and explicit form we finally have using what we know about complex numbers (see section Numbers page 243) and remarkable trigonometric functions (see section Trigonometry page 2519):

$$\begin{aligned}
\overrightarrow{\mathrm{O}P}=\begin{pmatrix}x\\ y\\ z\end{pmatrix}&=\begin{pmatrix}\psi\bar{\phi}+\bar{\psi}\phi\\ \mathrm{i}\left(\psi\bar{\phi}-\bar{\psi}\phi\right)\\ \psi\bar{\psi}-\phi\bar{\phi}\end{pmatrix}=\begin{pmatrix}e^{\mathrm{i}(\beta-\gamma)}\cos(\alpha)\sin(\alpha)+e^{\mathrm{i}(\gamma-\beta)}\cos(\alpha)\sin(\alpha)\\ \mathrm{i}\left(e^{\mathrm{i}(\beta-\gamma)}\cos(\alpha)\sin(\alpha)-e^{\mathrm{i}(\gamma-\beta)}\cos(\alpha)\sin(\alpha)\right)\\ \cos^2(\alpha)-\sin^2(\alpha)\end{pmatrix}\\
&=\begin{pmatrix}\left(e^{\mathrm{i}(\beta-\gamma)}+e^{-\mathrm{i}(\beta-\gamma)}\right)\cos(\alpha)\sin(\alpha)\\ \mathrm{i}\left(e^{\mathrm{i}(\beta-\gamma)}-e^{-\mathrm{i}(\beta-\gamma)}\right)\cos(\alpha)\sin(\alpha)\\ \cos^2(\alpha)-\sin^2(\alpha)\end{pmatrix}\\
&=\begin{pmatrix}(\cos(\beta-\gamma)+\mathrm{i}\sin(\beta-\gamma)+\cos(-(\beta-\gamma))+\mathrm{i}\sin(-(\beta-\gamma)))\cos(\alpha)\sin(\alpha)\\ \mathrm{i}(\cos(\beta-\gamma)+\mathrm{i}\sin(\beta-\gamma)-\cos(-(\beta-\gamma))-\mathrm{i}\sin(-(\beta-\gamma)))\cos(\alpha)\sin(\alpha)\\ \cos^2(\alpha)-\sin^2(\alpha)\end{pmatrix}\\
&=\begin{pmatrix}(2\cos(\beta-\gamma)+\mathrm{i}\sin(\beta-\gamma)-\mathrm{i}\sin(\beta-\gamma))\cos(\alpha)\sin(\alpha)\\ \mathrm{i}(\mathrm{i}\sin(\beta-\gamma)+\mathrm{i}\sin(\beta-\gamma))\cos(\alpha)\sin(\alpha)\\ \cos^2(\alpha)-\sin^2(\alpha)\end{pmatrix}\\
&=\begin{pmatrix}2\cos(\beta-\gamma)\cos(\alpha)\sin(\alpha)\\ -2\sin(\beta-\gamma)\cos(\alpha)\sin(\alpha)\\ \cos^2(\alpha)-\sin^2(\alpha)\end{pmatrix}=\begin{pmatrix}2\cos(\beta-\gamma)\dfrac{1}{2}\sin(2\alpha)\\ -2\sin(\beta-\gamma)\dfrac{1}{2}\sin(2\alpha)\\ \cos^2(\alpha)-\sin^2(\alpha)\end{pmatrix}\\
&=\begin{pmatrix}\cos(\beta-\gamma)\sin(2\alpha)\\ -\sin(\beta-\gamma)\sin(2\alpha)\\ \cos(2\alpha)\end{pmatrix}=\begin{pmatrix}\cos(\beta-\gamma)\sin(2\alpha)\\ \sin(\gamma-\beta)\sin(2\alpha)\\ \cos(2\alpha)\end{pmatrix}=\begin{pmatrix}\cos(\beta-\gamma)\sin(2\alpha)\\ -\sin(\beta-\gamma)\sin(2\alpha)\\ \cos(2\alpha)\end{pmatrix}
\end{aligned}\tag{6.8.21}$$

We notice easily that the norm of this vector is equal to 1.

This last relation also indicates us that 2α is the angle between $\mathrm{O}z$ and $\overrightarrow{\mathrm{O}P}$ (since the hypotenuse of vector's angle has a unit norm) and therefore by deduction $\gamma-\beta$ represents the angle between $\mathrm{O}x$ and the plane $(\mathrm{O}z,\overrightarrow{\mathrm{O}P})$:

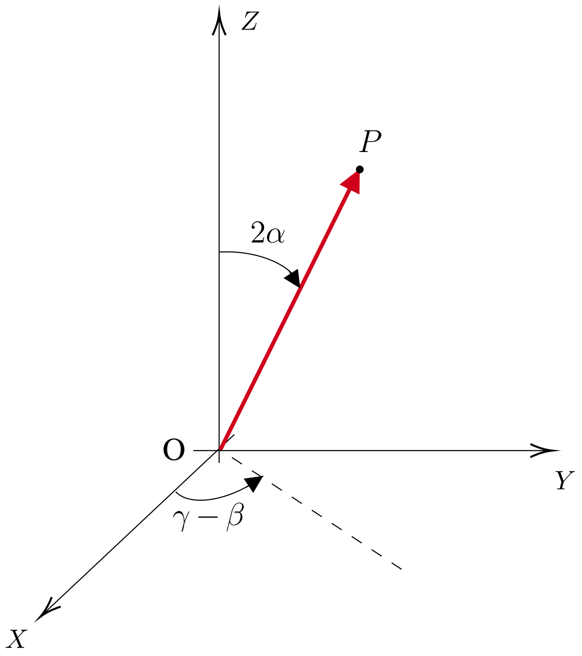

Figure 6.164: **Representation of the rotation**

The pair of complex numbers:

$$x=\psi\bar{\phi}+\bar{\psi}\phi \qquad y=\mathrm{i}\left(\psi\bar{\phi}-\bar{\psi}\phi\right) \tag{6.8.22}$$

is by definition a "unitary spinor" (it contains also all the information about z). Thus, as we have seen, a unitary spinor can also be expressed in the form:

$$\psi=e^{\mathrm{i}\beta}\cos(\alpha) \qquad \phi=e^{\mathrm{i}\gamma}\sin(\alpha) \tag{6.8.23}$$

As well any spinor can be written in the more general form:

$$\psi=\rho e^{\mathrm{i}\beta}\cos(\alpha) \qquad \phi=\rho e^{\mathrm{i}\gamma}\sin(\alpha) \tag{6.8.24}$$

The spin is essentially measured from the oriented z-axis as we have seen it yet with the previous figure.

The stereographic projection led us to represent certain vectors of the Euclidean space $\mathcal{E}^3$ with the elements of a complex two-dimensional vector space that is the "space of spinors".

Remark

This representation is not unique because the arguments of complex number are (in trigonometric form) determined at a given offset constant!

The reader who has already read a little bit the section on Wave Quantum Physics will probably noticed the strange (not innocent) similarity of the following identity and relations:

$$\psi\bar{\psi}+\phi\bar{\phi}=1 \qquad x=\psi\bar{\phi}+\bar{\psi}\phi \qquad y=\mathrm{i}\left(\psi\bar{\phi}-\bar{\psi}\phi\right) \tag{6.8.25}$$

compared to the de Broglie normalization condition (the integral over the entire space of the sum of the products of the complex wave functions and its conjugate is equal to the unit) and to the developments determining the continuity equation also in the section of Wave Quantum Physics .

Let us now see that for future needs, we can find two new vectors $\vec{v}_1, \vec{v}_2$ of Euclidean space $\mathcal{E}^3$ associated with a unitary spinor (ψ, ϕ) determined on the unit sphere. These vectors will have to be orthogonal to each other and with unit norm, each orthogonal to the vector $\overrightarrow{\mathrm{O}P}$.

To simplify the notations let us write $\vec{v}_3 = \overrightarrow{\mathrm{O}P}$ and $\vec{v}_i = (x_i, y_i, z_i), i \in \{1, 2, 3\}$.

The $\vec{v}_1, \vec{v}_2, \vec{v}_3$ vectors are of course bounded by the cross product (see section Vector Calculus page 1830):

$$\vec{v}_3 = \vec{v}_1 \times \vec{v}_2 \tag{6.8.26}$$

hence taking into account the expression of $\overrightarrow{\mathrm{O}P}$ components based on its associated spinor, and the fact that $\psi\bar{\psi} + \phi\bar{\phi} = 1$, we get:

$$\begin{aligned} x_3 &= y_1 z_2 - y_2 z_1 = 1 \cdot (\psi\bar{\phi} + \bar{\psi}\phi) = (\psi\bar{\psi} + \phi\bar{\phi})(\psi\bar{\phi} + \bar{\psi}\phi) \\ y_3 &= z_1 x_2 - z_2 x_1 = 1 \cdot \mathrm{i}(\psi\bar{\phi} - \bar{\psi}\phi) = \mathrm{i}(\psi\bar{\psi} + \phi\bar{\phi})(\psi\bar{\phi} - \bar{\psi}\phi) \\ z_3 &= x_1 y_2 - x_2 y_1 = 1 \cdot (\psi\bar{\psi} - \phi\bar{\phi}) \end{aligned} \tag{6.8.27}$$

Writing the orthogonality of vectors we get them obviously six additional equations. However the orientation of vectors $\vec{v}_1, \vec{v}_2$ being not fixed, there is some uncertainty in the values of their components. Let us select values such that:

$$\begin{aligned} x_1 + \mathrm{i}x_2 &= \psi^2 - \phi^2 = e^{2\mathrm{i}\beta}\cos^2(\alpha) - e^{2\mathrm{i}\gamma}\sin^2(\alpha) \\ y_1 + \mathrm{i}y_2 &= \mathrm{i}(\psi^2 + \phi^2) = \mathrm{i}\left(e^{2\mathrm{i}\beta}\cos^2(\alpha) + e^{2\mathrm{i}\gamma}\sin^2(\alpha)\right) \\ z_1 + \mathrm{i}z_2 &= -2\psi\phi = -2e^{\mathrm{i}(\beta+\gamma)}\cos(\alpha)\sin(\alpha) \end{aligned} \tag{6.8.28}$$

Taking the complex conjugate quantities of previous relation and summing, to have only real parts we have to write:

$$\begin{aligned} x_1 &= \frac{1}{2}(x_1 + \bar{x}_1) = \frac{1}{2}(\psi^2 + \bar{\psi}^2 - \phi^2 - \bar{\phi}^2) \\ y_1 &= \frac{1}{2}(y_1 + \bar{y}_1) = \frac{\mathrm{i}}{2}(\psi^2 - \bar{\psi}^2 + \phi^2 - \bar{\phi}^2) \\ z_1 &= -(\psi\phi + \bar{\psi}\bar{\phi}) \end{aligned} \tag{6.8.29}$$

We can control the norm is equal to the unit. Just check with the squared norm:

$$\begin{aligned} x_1^2 + y_1^2 + z_1^2 &= \frac{1}{4}(\psi^2 + \bar{\psi}^2 - \phi^2 - \bar{\phi}^2)^2 - \frac{1}{4}(\psi^2 - \bar{\psi}^2 + \phi^2 - \bar{\phi}^2)^2 + (\psi\phi + \bar{\psi}\bar{\phi})^2 \\ &= |\psi|^4 - \psi^2\phi^2 - \bar{\psi}^2\bar{\phi}^2 + |\phi|^4 + \psi^2\phi^2 + 2\psi\phi\bar{\psi}\bar{\phi} + \bar{\psi}^2\bar{\phi}^2 \\ &= |\psi|^4 + |\phi|^4 + 2\psi\phi\bar{\psi}\bar{\phi} = |\psi|^4 + |\phi|^4 + 2|\psi|^2|\phi|^2 \\ &= \cos^4(\alpha) + \sin^4(\alpha) + 2\cos^2(\alpha)\sin^2(\alpha) = \cos^4(\alpha) + \sin^4(\alpha) + 2\cos^2(\alpha)(1 - \cos^2(\alpha)) \\ &= \cos^4(\alpha) + \sin^4(\alpha) + 2\cos^2(\alpha) - 2\cos^4(\alpha) = -\cos^4(\alpha) + \sin^4(\alpha) + 2\cos^2(\alpha) \\ &= -\cos^4(\alpha) + (\sin^2(\alpha))^2 + 2\cos^2(\alpha) = -\cos^4(\alpha) + (1 - \cos^2(\alpha))^2 + 2\cos^2(\alpha) = 1 \end{aligned} \tag{6.8.30}$$

In the same way we get:

$$\begin{aligned}x_2&=\frac{\mathrm{i}}{2}(-\psi^2+\bar{\psi}^2+\phi^2-\bar{\phi}^2)\\y_2&=\frac{1}{2}(\psi^2+\bar{\psi}^2+\phi^2+\bar{\phi}^2)\\z_3&=\mathrm{i}(\psi\phi-\bar{\psi}\bar{\phi})\end{aligned}\tag{6.8.31}$$

We can easily check that these values restore well the relations of the vector cross product of $\vec{v}_2$. At any unitary spinor (ψ,ϕ) we can therefore associate three vectors $\vec{v}_1,\vec{v}_2,\vec{v}_3$. We can directly check that the vectors thus calculated are mutually orthogonal and with unit norm.

A reader has make us the request to show in much details as possible this affirmation for x_3. So let's go:

$$\begin{aligned}x_3&=y_1z_2-y_2z_1\\&=\left(\frac{\mathrm{i}}{2}(\psi^2-\bar{\psi}^2+\phi^2-\bar{\phi}^2)\right)(\mathrm{i}(\psi\phi-\bar{\psi}\bar{\phi}))-\left(\frac{1}{2}(\psi^2+\bar{\psi}^2+\phi^2+\bar{\phi}^2)\right)(-(\psi\phi+\bar{\psi}\bar{\phi}))\\&=-(\psi^2-\bar{\psi}^2+\phi^2-\bar{\phi}^2)(\psi\phi-\bar{\psi}\bar{\phi})+\frac{1}{2}(\psi^2+\bar{\psi}^2+\phi^2+\bar{\phi}^2)(\psi\phi+\bar{\psi}\bar{\phi})\\&=\frac{1}{2}\left[(\psi^2+\bar{\psi}^2+\phi^2+\bar{\phi}^2)(\psi\phi+\bar{\psi}\bar{\phi})-(\psi^2-\bar{\psi}^2+\phi^2-\bar{\phi}^2)(\psi\phi-\bar{\psi}\bar{\phi})\right]\\&=\frac{1}{2}\begin{bmatrix}\psi^2\psi\phi+\psi^2\bar{\psi}\bar{\phi}+\bar{\psi}^2\psi\phi+\bar{\psi}^2\bar{\psi}\bar{\phi}+\phi^2\psi\phi+\phi^2\bar{\psi}\bar{\phi}+\bar{\phi}^2\psi\phi+\bar{\phi}^2\bar{\psi}\bar{\phi}\\-\psi^2\psi\phi+\psi^2\bar{\psi}\bar{\phi}+\bar{\psi}^2\psi\phi-\bar{\psi}^2\bar{\psi}\bar{\phi}-\phi^2\psi\phi+\phi^2\bar{\psi}\bar{\phi}+\bar{\phi}^2\psi\phi-\bar{\phi}^2\bar{\psi}\bar{\phi}\end{bmatrix}\\&=\frac{1}{2}\left[2\psi^2\bar{\psi}\bar{\phi}+2\bar{\psi}^2\psi\phi+2\phi^2\bar{\psi}\bar{\phi}+2\bar{\phi}^2\psi\phi\right]=\psi^2\bar{\psi}\bar{\phi}+\bar{\psi}^2\psi\phi+\phi^2\bar{\psi}\bar{\phi}+\bar{\phi}^2\psi\phi\\&=\psi\bar{\psi}\psi\bar{\phi}+\bar{\psi}\psi\bar{\psi}\phi+\phi\bar{\psi}\phi\bar{\phi}+\bar{\phi}\psi\bar{\phi}\phi=\psi\bar{\psi}\left(\psi\bar{\phi}+\bar{\psi}\phi\right)+\phi\bar{\phi}\left(\phi\bar{\psi}+\bar{\phi}\psi\right)\\&=\psi\bar{\psi}\left(\bar{\psi}\phi+\psi\bar{\phi}\right)+\phi\bar{\phi}\left(\phi\bar{\psi}+\bar{\phi}\psi\right)=\psi\bar{\psi}\left(\phi\bar{\psi}+\bar{\phi}\psi\right)+\phi\bar{\phi}\left(\phi\bar{\psi}+\bar{\phi}\psi\right)\\&=\left(\psi\bar{\psi}+\phi\bar{\phi}\right)\left(\phi\bar{\psi}+\bar{\phi}\psi\right)=\left(\psi\bar{\psi}+\phi\bar{\phi}\right)\left(\bar{\psi}\phi+\psi\bar{\phi}\right)=\left(\psi\bar{\psi}+\phi\bar{\phi}\right)\left(\psi\bar{\phi}+\bar{\psi}\phi\right)\end{aligned}\tag{6.8.32}$$

6.8.2 Geometric Properties

We will study the transformations of vectors associated to a spinor to derive the corresponding properties of spinor transformation. As we know some special (trivial) rotations in space can always be expressed as the product of two plane symmetries, therefore we begin by studying these latter.

6.8.2.1 Plane Symmetries

Let us consider first the plan symmetry of a vector:

During a symmetry relative to a plane $\mathcal{P}$, any vector $\overrightarrow{\text{O}M}$ is transformed into a vector $\overrightarrow{\text{O}M'}$. Let us determine a matrix S representing this symmetry with respect to this plane!

Given $\overrightarrow{\text{O}A}$ a unit vector normal to the plane $\mathcal{P}$ and H the root of the perpendicular projection from any given point M of space on the plane $\mathcal{P}$:

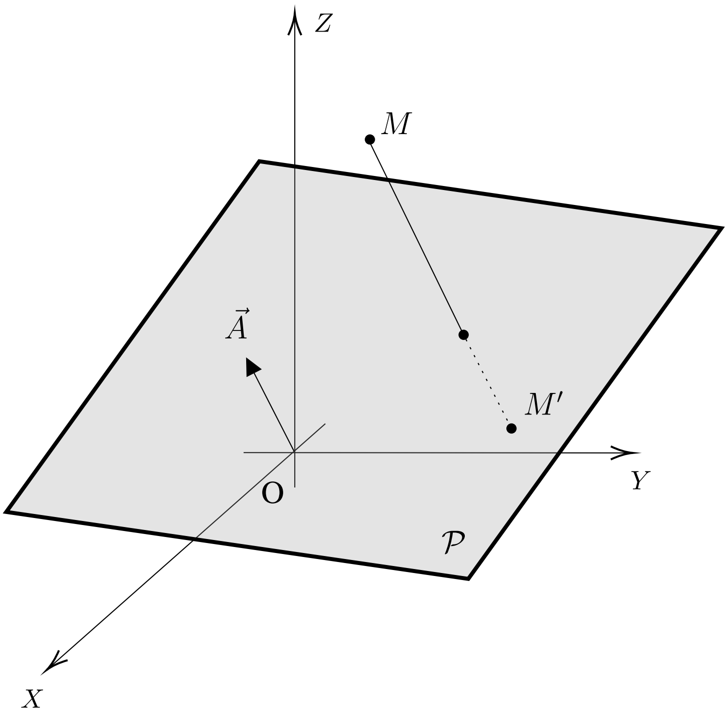

Figure 6.165: **Plane symmetry of a vector relatively to a plane**

Let M' be the symmetric point M with respect to the plane $\mathcal{P}$, we have:

$$\overrightarrow{\text{O}M'} = \overrightarrow{\text{O}M} + \overrightarrow{MM'} = \overrightarrow{\text{O}M} + 2\overrightarrow{MH} = \overrightarrow{\text{O}M} - 2\overrightarrow{\text{O}A}(\overrightarrow{\text{O}M} \circ \overrightarrow{\text{O}A}) \tag{6.8.33}$$

Given a_1, a_2, a_3 the cartesian components of $\overrightarrow{\text{O}A}$ and (x, y, z), (x', y', z') the respective components of the vectors $\overrightarrow{\text{O}M}, \overrightarrow{\text{O}M'}$, the above equation gives us the linear relations:

$$\begin{aligned} x' &= x - 2a_1(a_1x + a_2y + a_3z) \\ y' &= y - 2a_2(a_1x + a_2y + a_3z) \\ z' &= z - 2a_3(a_1x + a_2y + a_3z) \end{aligned} \tag{6.8.34}$$

The matrix S that takes us from vector $\vec{X}(x, y, z)$ to the vector $\vec{X}'(x, y, z)$ has therefore the following expression:

$$S = \begin{bmatrix} 1 - 2a_1^2 & -2a_1a_2 & -2a_1a_3 \\ -2a_2a_1 & 1 - 2a_2^2 & -2a_2a_3 \\ -2a_3a_1 & -2a_3a_2 & 1 - 2a_3^2 \end{bmatrix} \tag{6.8.35}$$

We keep in mind this result and let us now consider two vectors $(\vec{X}_1,\vec{X}_2)$ orthogonal to each other and unitary, defining as we have above seen a unitary spinor (ψ,ϕ) (we used the notation $\vec{v}_1,\vec{v}_2$ before). A symmetry with respect to a plane $\mathcal{P}$ transforms the vectors $\vec{X}_1,\vec{X}_2$ into vectors $\vec{X'}_1,\vec{X'}_2$ which are associated the spinor (ψ',ϕ').

Theorem 6.47. We will now show that the following transformation of the spinor (ψ,ϕ) into spinor $(\psi',\phi')=(x_3',y_3',z_3')$ is:

$$\boxed{\begin{pmatrix}\psi'\\ \phi'\end{pmatrix}=\begin{bmatrix}a_3 & a_1-\mathrm{i}a_2\\ a_1+\mathrm{i}a_2 & -a_3\end{bmatrix}=\mathcal{A}\begin{pmatrix}\psi\\ \phi\end{pmatrix}} \tag{6.8.36}$$

and transforms the vectors $\vec{X}_1,\vec{X}_2$ into vectors $\vec{X}_1',\vec{X}_2'$, these vectors being deduced respectively - as we will just show it - from each other by a single plane symmetry and the matrix $\mathcal{A}$ represents well the sought transformation.

The previous relation gives us therefore:

$$\begin{aligned}\psi'&=a_3\psi+(a_1-\mathrm{i}a_2)\phi\\ \phi'&=(a_1+\mathrm{i}a_2)\phi-a_3\phi\end{aligned} \tag{6.8.37}$$

In all we have so far the previous set of relations and:

$$\vec{X}_3'=(\phi',\psi')\begin{cases}x_1'+\mathrm{i}x_2'=\phi'^2+\psi'^2\\ y_1'+\mathrm{i}y_2'=\mathrm{i}(\psi'^2+\phi'^2)\\ z_1'+\mathrm{i}z_2'=-2\psi'\phi'\end{cases} \tag{6.8.38}$$

Therefore we can deduce:

$$\begin{aligned}x_3'&=\psi'^2-\phi'^2=(a_3\psi+(a_1-\mathrm{i}a_2)\phi)^2-((a_1+\mathrm{i}a_2)\psi-a_3\phi)^2\\
&=(a_3^2\psi^2+2a_3\psi(a_1-\mathrm{i}a_2)\phi+(a_1-\mathrm{i}a_2)^2\phi^2)-((a_1+\mathrm{i}a_2)^2\phi^2-a(a_1+\mathrm{i}a_2)\psi a_3\phi+a_3^2\phi^2)\\
&=(a_3^2\psi^2+2a_3\psi(a_1-\mathrm{i}a_2)\phi+(a_1^2-2a_1\mathrm{i}a_2-a_2^2)\phi^2)\\
&-((a_1^2+2a_1\mathrm{i}a_2-a_2^2)\phi^2-2(a_1+\mathrm{i}a_2)\psi a_3\phi+a_3^2\phi^2)\\
&=a_3^2\psi^2+2a_1a_3\psi\phi-2\mathrm{i}a_2a_3\psi\phi+a_1^2\phi^2-2a_1\mathrm{i}a_2\phi^2-a_2^2\phi^2\\
&-a_1^2\psi^2-2a_1\mathrm{i}a_2\psi^2+a_2^2\psi^2+2a_1a_3\psi\phi+2\mathrm{i}a_2a_2\psi\phi-a_3^2\phi^2\\
&=\left[-a_1^2+a_2^2+a_3^2\right](\psi^2-\phi^2)-2a_1a_2\mathrm{i}(\psi^2+\phi^2)-2a_1a_2(-2\psi\phi)\end{aligned}$$

$$\begin{aligned}y_3'&=\mathrm{i}(\psi'^2+\phi'^2)=\mathrm{i}\left[(a_3\psi+(a_1-\mathrm{i}a_2)\phi)^2+((a_1+\mathrm{i}a_2)\psi-a_3\phi)^2\right]\\
&=\mathrm{i}\left[(a_3^2\psi^2+2a_3\psi(a_1-\mathrm{i}a_2)\phi+(a_1-\mathrm{i}a_2)^2\phi^2)+((a_1+\mathrm{i}a_2)^2\psi^2-2(a_1+\mathrm{i}a_2)\psi a_3\phi+a_3^2\phi^2)\right]\\
&=\mathrm{i}(a_3^2\psi^2+2a_3\psi(a_1-\mathrm{i}a_2)\phi+(a_1^2-2a_1\mathrm{i}a_2-a_2^2)\phi^2)\\
&+\mathrm{i}((a_1^2+2a_1\mathrm{i}a_2-a_2^2)\psi^2-2(a_1+\mathrm{i}a_2)\psi a_2\phi+a_3^2\phi^2)\\
&=\mathrm{i}a_3^2\psi^2+2\mathrm{i}a_1a_2\psi\phi+2a_2a_3\psi\phi+\mathrm{i}a_1^2\phi^2+2a_1a_2\phi^2-\mathrm{i}a_2^2\phi^2\\
&+\mathrm{i}a_1^2\psi^2-2a_1a_2\psi^2-\mathrm{i}a_2^2\psi^2-2a_1a_3\psi\phi+2a_2a_3\psi\phi+\mathrm{i}a_3^2\phi^2\\
&=-2a_1a_2(\psi^2-\phi^2)-2a_2a_3(-2\psi\phi)+(a_1^2-a_2^2+a_3^2)\mathrm{i}(\psi^2+\phi^2)\end{aligned}$$

$$\begin{aligned}z_3'&=-2\psi'\phi'=-2(a_2\psi+(a_1-\mathrm{i}a_2)\phi)((a_1+\mathrm{i}a_2)\psi-a_3\phi)\\
&=-2(a_3\psi+a_1\phi-\mathrm{i}a_2\phi)(a_1\psi+\mathrm{i}a_2\psi-a_3\phi)\\
&=-2a_3a_1(\psi^2-\phi^2)-2a_2a_3\mathrm{i}(\psi^2+\phi^2)+(a_1^2+a_2^2-a_3^2)(-2\psi\phi)\end{aligned} \tag{6.8.39}$$

After, using the fact that $\|\vec{A}\|=a_1^2+a_2^2+a_3^2=1$, we get:

$$\begin{aligned}x_3'&=[1-2a_1^2]x_3-2a_1a_2y_3-2a_1a_3z_3\\y_3'&=-2a_1a_2x_3+[1-2a_2^2]y_3-2a_2a_3z_3\\z_3'&=-2a_3a_1x_3-2a_3a_2y_3+[1-2a_3^2]z_3\end{aligned}\tag{6.8.40}$$

So we fall well back on the symmetry matrix:

$$S=\begin{bmatrix}1-2a_1^2 & -2a_1a_2 & -2a_1a_3\\-2a_2a_1 & 1-2a_2^2 & -2a_2a_3\\-2a_3a_1 & -2a_3a_2 & 1-2a_3^2\end{bmatrix}\tag{6.8.41}$$

Thus, the matrix that we will see again in the section of Relativistic Quantum Physics:

$$\boxed{\mathcal{A}=\begin{bmatrix}a_3 & a_1-\mathrm{i}a_2\\a_1+\mathrm{i}a_2 & -a_3\end{bmatrix}}\tag{6.8.42}$$

$\mathcal{A}$ therefore generates the transformation of a spinor (ψ,ϕ) into a spinor (ψ',ϕ') such that the associated vectors $(\vec{X}_1,\vec{X}_2)$ can be deduced respectively from $(\vec{X}_1',\vec{X}_2')$ by a planar symmetry.

6.8.2.2 Rotations

As we have saw it in the section of Euclidean Geometry, it is possible to rotate a vector in the plane or in space using matrices. Similarly, by extension, it is clear that the multiplication of two rotations is a rotation (that is the elementary linear algebra - at least we consider it as is).

Consider therefore two planes P,Q whose intersection generates a line L and let us denote $\vec{A}(a_1,a_2,a_3)$ and $\vec{B}(b_1,b_2,b_2)$ the unit vectors carried by the respective normal vectors (see section Vector Calculus page 1801) to these two intersecting planes in L:

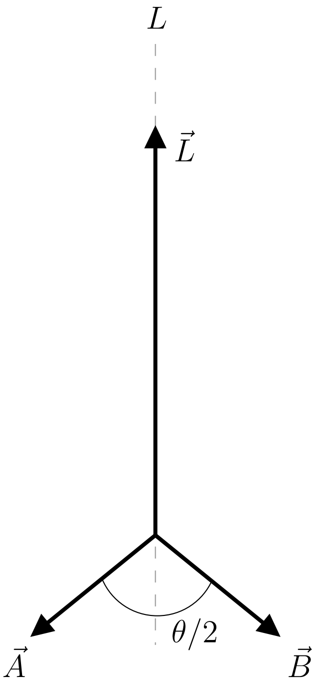

Figure 6.166: **Illustrated intersection of two planes**

Let us denote by $\theta/2$ the angle of the vectors $\vec{A},\vec{B}$ between them (the reason for this notation comes from our study of quaternions (see section Numbers page 261)). Given $\vec{L}$ the unit direction vector carried by the line L resulting from the intersection of planes P,Q and such that:

$$\vec{A}\times\vec{B}=\vec{L}\sin\left(\frac{\theta}{2}\right) \tag{6.8.43}$$

Explanations: $\vec{A},\vec{B}$ are unitary but not necessarily perpendicular and we still need to ensure that $\vec{L}$ is a unit vector (the norm equal to unity!). Therefore, the above relation ensures that:

$$\|\vec{A}\|\cdot\|\vec{B}\|\cancel{\sin\left(\frac{\theta}{2}\right)}=\|\vec{L}\|\cancel{\sin\left(\frac{\theta}{2}\right)}\Rightarrow\|\vec{A}\|\cdot\|\vec{B}\|=\|\vec{L}\|=L_1^2+L_2^2+L_3^2=1 \tag{6.8.44}$$

The previous vector product gives us for the components of $\vec{L}$:

$$L_1\sin\left(\frac{\theta}{2}\right)=a_2b_3-a_3b_2 \tag{6.8.45}$$

$$L_2\sin\left(\frac{\theta}{2}\right)=a_3b_1-a_1b_3 \tag{6.8.46}$$

$$L_3\sin\left(\frac{\theta}{2}\right)=a_1b_2-a_2b_1 \tag{6.8.47}$$

On the other hand, the scalar product can be written:

$$\vec{A}\circ\vec{B}=a_1b_1+a_2b_2+a_3b_3=\|\vec{A}\|\cdot\|\vec{B}\|\cos\left(\frac{\theta}{2}\right)=\cos\left(\frac{\theta}{2}\right) \tag{6.8.48}$$

Remark

We will use these two planes as symmetry planes for our rotations.

As we have noticed previously, a rotation in $\mathcal{E}^3$ can always be done with more than two plane symmetries. Thus, a rotation can be denoted by the application (multiplication) of two matrices of symmetry according to the results obtained previously:

$$R\left(\vec{L},\frac{\theta}{2}\right)=\begin{bmatrix}b_3 & b_1-\mathrm{i}b_2\\ b_1+\mathrm{i}b_2 & -b_3\end{bmatrix}\begin{bmatrix}a_3 & a_1-\mathrm{i}a_2\\ a_1+\mathrm{i}a_2 & -a_3\end{bmatrix} \tag{6.8.49}$$

Developing the product of these two matrices and taking into account the relations arising from vector and dot product we get:

$$R\left(\vec{L},\frac{\theta}{2}\right)=\begin{bmatrix}\cos\left(\frac{\theta}{2}\right)-\mathrm{i}L_3\sin\left(\frac{\theta}{2}\right) & -(\mathrm{i}L_1+L_2)\sin(\left(\frac{\theta}{2}\right)\\ (-\mathrm{i}L_1+L_2)\sin\left(\frac{\theta}{2}\right) & \cos\left(\frac{\theta}{2}\right)+\mathrm{i}L_3\sin(\left(\frac{\theta}{2}\right)\end{bmatrix} \tag{6.8.50}$$

Thus, we can write the transformation of a spinor (ψ,ϕ) and a spinor (ψ',ϕ') with a matrix of the form:

$$R=\begin{bmatrix}a & b\\ -\bar{b} & \bar{a}\end{bmatrix} \tag{6.8.51}$$

whose parameters are named "Cayley-Klein parameters".

The matrix $R\left(\vec{L},\frac{\theta}{2}\right)$ can be written in another form if we do a limited development for infinitely small rotations $\theta/2=\varepsilon/2$ (that's where the physics comes back...):

$$\cos\left(\frac{\varepsilon}{2}\right)=1-\frac{1}{2}\left(\frac{\varepsilon}{2}\right)^2+\ldots \qquad \sin\left(\frac{\varepsilon}{2}\right)=\frac{\varepsilon}{2}-\frac{1}{6}\left(\frac{\varepsilon}{2}\right)^3+\ldots \tag{6.8.52}$$

Using only the first order terms, the rotation matrix is finally written:

$$\boxed{R\left(\vec{L},\frac{\theta}{2}\right)=\begin{bmatrix}1-\mathrm{i}L_3\frac{\varepsilon}{2} & -(\mathrm{i}L_1+L_2)\frac{\varepsilon}{2}\\ (-\mathrm{i}L_1+L_2)\frac{\varepsilon}{2} & 1+\mathrm{i}L_3\frac{\varepsilon}{2}\end{bmatrix}=\begin{bmatrix}1&0\\0&1\end{bmatrix}+\frac{\varepsilon}{2}\begin{bmatrix}-\mathrm{i}L_3 & -(\mathrm{i}L_1+L_2)\\ (-\mathrm{i}L_1+L_2) & \mathrm{i}L_3\end{bmatrix}} \tag{6.8.53}$$

This matrix is the limited development of the matrix of rotation in the neighbourhood of the identity matrix, the latter obviously corresponding to the zero rotation. We note also the latter in the form:

$$R\left(\vec{L},\frac{\theta}{2}\right)=\sigma_0+\varepsilon\chi(\vec{L}) \tag{6.8.54}$$

where the matrix σ_0 is the identity matrix of order two and $\chi(\vec{L})$ is named the "infinitesimal rotation matrix". Now, if we put $L_1=1,L_2=L_3=0$ in $\chi(\vec{L})$ we get:

$$\chi(\vec{L})=\chi(\mathrm{O}x)=\frac{1}{2}\begin{bmatrix}0&-\mathrm{i}\\-\mathrm{i}&0\end{bmatrix}=-\frac{\mathrm{i}}{2}\begin{bmatrix}0&1\\1&0\end{bmatrix} \tag{6.8.55}$$

How to interpret this result? Well it's quite simple, choose $L_1=1,L_2=L_3=0$ gives us a collinear vector $\vec{L}$ to the axis Ox. Therefore, we can very well imagine the planes generating the axis Ox that carries $\vec{L}$. As $\varepsilon/2$ (verbatim $\theta/2$) is generated by the vectors $\vec{A},\vec{B}$ perpendicular to $\vec{L}$ and thus to Ox, then the angle $\varepsilon/2$ (or its variation) represents a variation of the direction of the normal planes to $\vec{A},\vec{B}$ which by symmetry are used to construct the rotation (recall that $\vec{A},\vec{B}$are not necessarily mutually orthogonal). So by extension, having $L_1=1,L_2=L_3=0$ allows us then only to make rotations (symmetries) around the x-axis.

Similarly, a rotation about the y-axis corresponds to $L_2=1,L_1=L_3=0$, which gives:

$$\chi(\vec{L})=\chi(\mathrm{O}y)=\frac{1}{2}\begin{bmatrix}0&-1\\1&0\end{bmatrix}=-\frac{\mathrm{i}}{2}\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix} \tag{6.8.56}$$

and the same with $L_3=1,L_1=L_2=0$ we finally have:

$$\chi(\vec{L})=\chi(\mathrm{O}z)=\frac{1}{2}\begin{bmatrix}-\mathrm{i}&0\\0&\mathrm{i}\end{bmatrix}=-\frac{\mathrm{i}}{2}\begin{bmatrix}1&0\\0&-1\end{bmatrix} \tag{6.8.57}$$

The three matrices:

$$\begin{aligned}\chi(\vec{L})&=\chi(\mathrm{O}x)=\frac{1}{2}\begin{bmatrix}0&-\mathrm{i}\\-\mathrm{i}&0\end{bmatrix}=-\frac{\mathrm{i}}{2}\begin{bmatrix}0&1\\1&0\end{bmatrix}\\ \chi(\vec{L})&=\chi(\mathrm{O}y)=\frac{1}{2}\begin{bmatrix}0&-1\\1&0\end{bmatrix}=-\frac{\mathrm{i}}{2}\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix}\\ \chi(\vec{L})&=\chi(\mathrm{O}z)=\frac{1}{2}\begin{bmatrix}-\mathrm{i}&0\\0&\mathrm{i}\end{bmatrix}=-\frac{\mathrm{i}}{2}\begin{bmatrix}1&0\\0&-1\end{bmatrix}\end{aligned} \tag{6.8.58}$$

are rotation matrices in the space of "two-dimensional spinors". Physicists and mathematicians say that these matrices are an irreducible representation of dimension two of the group "$\mathrm{SU}(2)$" or named "special group of spatial rotations $\mathrm{SU}(2)$" (see section Set Algebra page 1425).

The previous infinitesimal matrices therefore show us in a skilful way the following matrices:

$$\boxed{\sigma_1=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix},\sigma_2=\begin{bmatrix}0 & -\mathrm{i}\\ \mathrm{i} & 0\end{bmatrix},\sigma_3=\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix}} \tag{6.8.59}$$

These matrices are named "Pauli matrices" and we will find them again in the section of Relativistic Quantum Physics as part of the study of the Dirac equation and the determination of its explicit solutions (using spinors).

Using Pauli matrices, the infinitesimal rotations matrix can finally be written:

$$R\left(\vec{L},\frac{\theta}{2}\right)=\sigma_0+\varepsilon\chi(\vec{L})=\sigma_0-\left(\mathrm{i}\frac{\varepsilon}{2}\right)(L_1\sigma_1+L_2\sigma_2+L_3\sigma_3) \tag{6.8.60}$$

Let us define a vector $\vec{\sigma}$, named "Pauli vector", whose components are the Pauli matrices:

$$\vec{\sigma}=(\sigma_1,\sigma_2,\sigma_3) \tag{6.8.61}$$

The expression $L_1\sigma_1+L_2\sigma_2+L_3\sigma_3$ can be written as a sort of dot product which represents a sum of matrices (the arrow above the sigma is sometimes omitted if no confusion is possible):

$$\boxed{\vec{L}\circ\vec{\sigma}=L_1\sigma_1+L_2\sigma_2+L_3\sigma_3} \tag{6.8.62}$$

The limited development is then written:

$$R\left(\vec{L},\frac{\theta}{2}\right)=\sigma_0+\varepsilon\chi(\vec{L})=\sigma_0-\left(\mathrm{i}\frac{\varepsilon}{2}\right)(L_1\sigma_1+L_2\sigma_2+L_3\sigma_3)=\sigma_0-\left(\mathrm{i}\frac{\varepsilon}{2}\right)\vec{L}\circ\vec{\sigma} \tag{6.8.63}$$

The rotations matrix:

$$R\left(\vec{L},\frac{\theta}{2}\right)=\begin{bmatrix}\cos\left(\frac{\theta}{2}\right)-\mathrm{i}L_3\sin\left(\frac{\theta}{2}\right) & -(\mathrm{i}L_1+L_2)\sin(\left(\frac{\theta}{2}\right)\\ (-\mathrm{i}L_1+L_2)\sin\left(\frac{\theta}{2}\right) & \cos\left(\frac{\theta}{2}\right)+\mathrm{i}L_3\sin(\left(\frac{\theta}{2}\right)\end{bmatrix} \tag{6.8.64}$$

can using Pauli matrices be written in the remarkable form under the assumption of small angles:

$$\boxed{R\left(\vec{L},\frac{\theta}{2}\right)=\cos\left(\frac{\theta}{2}\right)\sigma_0-\mathrm{i}\sin\left(\frac{\theta}{2}\right)\vec{L}\circ\vec{\sigma}} \tag{6.8.65}$$

Expression that we will a lot in the section of Quantum Computing to express the R matrices explicitly and also in the section of Set Algebra page 1417.

What is written sometimes:

$$R\left(\vec{L},\theta\right)=\cos\left(\frac{\theta}{2}\right)\mathbb{1}-\mathrm{i}\sin\left(\frac{\theta}{2}\right)\vec{L}\circ\vec{\sigma} \tag{6.8.66}$$

Which can also be written in an extensive form:

$$\boxed{R\left(\vec{L},\frac{\theta}{2}\right)=\cos\left(\frac{\theta}{2}\right)\sigma_0-L_1\mathrm{i}\sin\left(\frac{\theta}{2}\right)\sigma_1-L_2\mathrm{i}\sin\left(\frac{\theta}{2}\right)\sigma_2-L_3\mathrm{i}\sin\left(\frac{\theta}{2}\right)\sigma_3} \tag{6.8.67}$$

which has the form of a quaternion of angle θ (don't forget that this is only for small angles!) and of axis $\vec{L}$. Hence the reason that have from the beginning chosen the notation $\varepsilon/2$.

It is clear, so that the analogy with quaternions to be stronger, that the 2×2 Pauli matrices are a set of four linearly independent matrices! As the canonical basis for quaternions!

If we denote by $\vec{L}(L_1,L_2,L_3)=\vec{X}(x,y,z)$ then the "spinor product" is finally defined by:

$$\boxed{L_1\sigma_1+L_2\sigma_2+L_3\sigma_3=x\sigma_1+y\sigma_2+z\sigma_3=\vec{X}\circ\vec{\sigma}=\begin{bmatrix}z & x-\mathrm{i}y\\ x+\mathrm{i}y & -z\end{bmatrix}} \tag{6.8.68}$$

This matrix constitutes as we have already mentioned, to the limited development of the rotation matrix in the neighbourhood of the identity matrix, the components of $\vec{x}$ being associated with a spinor whose rotation is through the double symmetry defined by two planes whose intersection is defined by the vector $\vec{X}$.

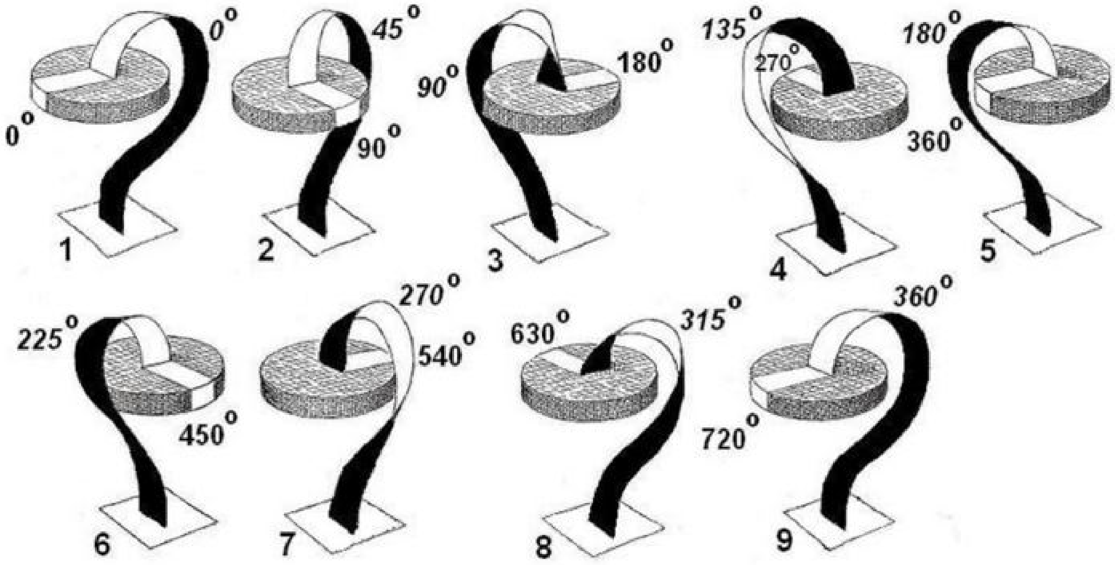
We can also notice the interesting consequence that a rotation of 2π (360°) rotation does not restore the object to its original position!!!

Indeed:

$$\begin{gathered}R(\vec{L},0)=\cos(0)\mathbb{1}-\mathrm{i}\sin(0)\vec{L}\circ\vec{\sigma}=\mathbb{1}\\ R(\vec{L},2\pi)=\cos(\pi)\mathbb{1}-\mathrm{i}\sin(\pi)\vec{L}\circ\vec{\sigma}=-\mathbb{1}\\ R(\vec{L},4\pi)=\cos(2\pi)\mathbb{1}-\mathrm{i}\sin(2\pi)\vec{L}\circ\vec{\sigma}=\mathbb{1}\end{gathered} \tag{6.8.69}$$

Therefore we need a rotation of 4π (720°) to make a full turn! This corresponds to the spin of $^1\!/_2$. It takes two turns to find that the object reappears equivalently (this is counter intuitive and can make thing we are dealing with object having higher dimensions that what we expected!). We then say that the representation of rotations is "bivaluated".

Schematically this can be represented as:



0°
0°
1
45°
90°
2
90°
180°
3
135°
270°
4
180°
360°
5
225°
450°
6
270°
540°
7
630°
315°
720°
8
360°

Figure 6.167: **Spinor full rotation (special example)**

Or you can consider the analogy that is to hold a tea cup on the palm of your hand and you turn your hand by maintaining it flat to regain its (the hand, not the cup!) original position. You will see that your hand has to do two laps!

6.8.2.3 Properties of Pauli Matrices

The reader can easily check (if this is not the case he can always contact us and we will write the details) the following main properties of the Pauli matrices, some of which will be used in the section of Relativistic Quantum Physics.

First notice that all three of the Pauli matrices can be compacted into a single expression:

$$\sigma_j=\begin{pmatrix} \delta_{j3} & \delta_{j1}-\mathrm{i}\delta_{j2} \\ \delta_{j1}+\mathrm{i}\delta_{j2} & -\delta_{j3} \end{pmatrix} \tag{6.8.70}$$

where δ_{jk} is the Kronecker delta, which equals $+1$ if $j=k$ and 0 otherwise.

So let's go now for the properties:

P1. Unitarity:

$$\sigma_1^2=\sigma_2^2=\sigma_3^2=\sigma_0 \tag{6.8.71}$$

P2. Anticommutativity:

$$\sigma_i\sigma_j=-\sigma_j\sigma_i \tag{6.8.72}$$

or $i\neq j$ and $i,j=1,2,3$.

The last two properties gives us:

$$\sigma_i\sigma_j+\sigma_j\sigma_i=2\delta_{ij}\sigma_0 \tag{6.8.73}$$

with $i,j=1,2,3$.

P3. Cyclicity:

$$\sigma_1\sigma_2=\mathrm{i}\sigma_3 \quad \sigma_2\sigma_3=\mathrm{i}\sigma_1 \quad \sigma_3\sigma_1=\mathrm{i}\sigma_2 \tag{6.8.74}$$

P4. Commutativity:

$$\begin{aligned}\sigma_1\sigma_2-\sigma_2\sigma_1&=2\mathrm{i}\sigma_3\\ \sigma_3\sigma_1-\sigma_1\sigma_3&=2\mathrm{i}\sigma_2\\ \sigma_2\sigma_3-\sigma_3\sigma_2&=2\mathrm{i}\sigma_1\end{aligned} \tag{6.8.75}$$

P5. Vector product:

Given the square of the different σ by noting abusively by "1" the unitary matrix (we change the indices to give you the habit to use other common notations):

$$\begin{aligned}\sigma_x\sigma_x&=\begin{bmatrix}0&1\\1&0\end{bmatrix}\begin{bmatrix}0&1\\1&0\end{bmatrix}=\begin{bmatrix}1&0\\0&1\end{bmatrix}=1\\ \sigma_y\sigma_y&=\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix}\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix}=\begin{bmatrix}1&0\\0&1\end{bmatrix}=1\\ \sigma_z\sigma_z&=\begin{bmatrix}1&0\\0&-1\end{bmatrix}\begin{bmatrix}1&0\\0&-1\end{bmatrix}=\begin{bmatrix}1&0\\0&1\end{bmatrix}=1\end{aligned} \tag{6.8.76}$$

Leading us to write that (square norm of the Pauli vector):

$$\sigma=\sigma_x^2+\sigma_y^2+\sigma_z^2=3\cdot\mathbb{1}=3\begin{bmatrix}1&0\\0&1\end{bmatrix} \tag{6.8.77}$$

Let us consider now the following products:

$$\begin{gathered}
\sigma_x\sigma_y=\begin{bmatrix}0&1\\1&0\end{bmatrix}\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix}=\begin{bmatrix}\mathrm{i}&0\\0&-\mathrm{i}\end{bmatrix}=\mathrm{i}\begin{bmatrix}1&0\\0&-1\end{bmatrix}=\mathrm{i}\sigma_z\\
\sigma_x\sigma_y=\mathrm{i}\sigma_z\\
\sigma_x\sigma_z=\begin{bmatrix}0&1\\1&0\end{bmatrix}\begin{bmatrix}1&0\\0&-1\end{bmatrix}=\begin{bmatrix}0&-1\\1&0\end{bmatrix}=\begin{bmatrix}0&\mathrm{i}\cdot\mathrm{i}\\-\mathrm{i}\cdot\mathrm{i}&0\end{bmatrix}=\mathrm{i}\begin{bmatrix}0&\mathrm{i}\\-\mathrm{i}&0\end{bmatrix}=-\mathrm{i}\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix}=-\mathrm{i}\sigma_y\\
\sigma_x\sigma_z=-\mathrm{i}\sigma_y\\
\sigma_z\sigma_x=\begin{bmatrix}1&0\\0&-1\end{bmatrix}\begin{bmatrix}0&1\\1&0\end{bmatrix}=\begin{bmatrix}0&1\\-1&0\end{bmatrix}=\begin{bmatrix}0&-\mathrm{i}\cdot\mathrm{i}\\\mathrm{i}\cdot\mathrm{i}&0\end{bmatrix}=\mathrm{i}\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix}=\mathrm{i}\sigma_y\\
\sigma_z\sigma_x=\mathrm{i}\sigma_y\\
\sigma_y\sigma_z=\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix}\begin{bmatrix}1&0\\0&-1\end{bmatrix}=\begin{bmatrix}0&\mathrm{i}\\\mathrm{i}&0\end{bmatrix}=\mathrm{i}\begin{bmatrix}0&1\\1&0\end{bmatrix}=\mathrm{i}\sigma_x\\
\sigma_y\sigma_z=\mathrm{i}\sigma_x\\
\sigma_z\sigma_y=\begin{bmatrix}1&0\\0&-1\end{bmatrix}\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix}=\begin{bmatrix}0&-\mathrm{i}\\-\mathrm{i}&0\end{bmatrix}=-\mathrm{i}\begin{bmatrix}0&1\\1&0\end{bmatrix}=-\mathrm{i}\sigma_x\\
\sigma_z\sigma_y=-\mathrm{i}\sigma_x
\end{gathered} \tag{6.8.78}$$

All these relations can be summarized into a unique one (!):

$$\boxed{\sigma_i\sigma_j=\delta_{ij}\mathbb{1}+\mathrm{i}\varepsilon_{ijk}\sigma_k} \tag{6.8.79}$$

where for recall (see section Tensor Calculus page 2044) the Kronecker symbol is defined by:

$$\delta_{ij}=\delta^{ij}=\delta_i^j=\begin{cases}1&\text{if } i=j\\0&\text{if } i\neq j\end{cases} \tag{6.8.80}$$

In three dimensions, the Levi-Civita symbol is defined as follows:

$$\varepsilon_{ijk}=\begin{cases}+1&\text{if }(i,j,k)\text{ is }(1,2,3),(2,3,1)\text{ or }(3,1,2),\\-1&\text{if }(i,j,k)\text{ is }(3,2,1),(1,3,2)\text{ or }(2,1,3),\\\ \ 0&\text{if }i=j\text{ or }j=k\text{ or }k=i\end{cases} \tag{6.8.81}$$

i.e. ε_{ijk} is 1 if (i,j,k) is an even permutation of $(1,2,3)$ or in the natural order $(1,2,3)$, -1 if it is an odd permutation, and 0 if any index is repeated. In three dimensions only, the cyclic permutations of $(1,2,3)$ are all even permutations, similarly the anti-cyclic permutations are all odd permutations. This means in 3D it is sufficient to take cyclic or anti-cyclic permutations of $(1,2,3)$ and easily obtain all the even or odd permutations.

The boxed relation above can be presented as a Cayley table:

×	σ_x	σ_y	σ_z
σ_x	$\mathbb{1}$	$i\sigma_z$	$-\mathrm{i}\sigma_y$
σ_y	$-\mathrm{i}\sigma_z$	$\mathbb{1}$	$\mathrm{i}\sigma_x$
σ_z	$\mathrm{i}\sigma_y$	$-\mathrm{i}\sigma_x$	$\mathbb{1}$

(6.8.82)

We see therefore that the Pauli matrices are involutory (a square matrix is its own inverse):

$$\sigma_1^2=\sigma_2^2=\sigma_3^2=-i\sigma_1\sigma_2\sigma_3=\begin{pmatrix}1&0\\0&1\end{pmatrix}=\mathbb{1} \tag{6.8.83}$$

We also have:

$$\begin{aligned}\sigma_x\sigma_y-\sigma_y\sigma_x&=2\mathrm{i}\sigma_z\\ \sigma_y\sigma_z-\sigma_z\sigma_y&=2\mathrm{i}\sigma_x\\ \sigma_z\sigma_x-\sigma_x\sigma_z&=2\mathrm{i}\sigma_y\end{aligned} \tag{6.8.84}$$

That can be summarized into:

$$[\sigma_j,\sigma_k]=2\mathrm{i}\varepsilon_{jkl}\sigma_l \tag{6.8.85}$$

We fall back here on the components of the vector product:

$$\vec{\sigma}\times\vec{\sigma}=2\mathrm{i}\vec{\sigma} \tag{6.8.86}$$

Now let us develop an important spinor identity which will be useful to us in the section of Relativistic Quantum Physics:

$$\begin{aligned}(\vec{\sigma}\circ\vec{a})(\vec{\sigma}\circ\vec{b})&=(\sigma_1a_1+\sigma_2a_2+\sigma_3a_3)(\sigma_1b_1+\sigma_2b_2+\sigma_3b_3)\\ &=\sum_{i,j}a_i\sigma_ib_j\sigma_j\\ &=\begin{bmatrix}a_z&a_x-\mathrm{i}a_y\\a_x+\mathrm{i}a_y&-a_z\end{bmatrix}\begin{bmatrix}b_z&b_x-\mathrm{i}b_y\\b_x+\mathrm{i}b_y&-b_z\end{bmatrix}\\ &=\begin{bmatrix}a_zb_z+(b_x+\mathrm{i}b_y)(a_x-\mathrm{i}a_y)&a_z(b_x-\mathrm{i}b_y)-b_z(a_x-\mathrm{i}a_y)\\b_z(a_x+\mathrm{i}a_y)-a_z(b_x+\mathrm{i}b_y)&(b_x-\mathrm{i}b_y)(a_x+\mathrm{i}a_y)+a_zb_z\end{bmatrix}\\ &=\begin{bmatrix}a_zb_z+b_xa_x+b_ya_y+\mathrm{i}(b_ya_x-b_xa_y)&a_zb_x-\mathrm{i}a_zb_y-b_za_x+b_z\mathrm{i}a_y\\b_za_x+b_z\mathrm{i}a_y-a_zb_x-\mathrm{i}a_zb_y&a_zb_z+b_xa_x+b_ya_y+\mathrm{i}(b_xa_y-b_ya_x)\end{bmatrix}\\ &=\begin{bmatrix}a_xb_x+a_yb_y+a_zb_z&0\\0&a_xb_x+a_yb_y+a_zb_z\end{bmatrix}\\ &+\begin{bmatrix}\mathrm{i}(b_ya_x-b_xa_y)&a_zb_x-b_za_x+\mathrm{i}(b_za_y-a_zb_y)\\b_za_x-a_zb_x+\mathrm{i}(b_za_y-a_zb_y)&\mathrm{i}(b_xa_y-b_ya_x)\end{bmatrix}\\ &=(\vec{a}\circ\vec{b})\mathbb{1}+\begin{bmatrix}\mathrm{i}(b_ya_x-b_xa_y)&a_zb_x-b_za_x+\mathrm{i}(b_za_y-a_zb_y)\\b_za_x-a_zb_x+\mathrm{i}(b_za_y-a_zb_y)&\mathrm{i}(b_xa_y-b_ya_x)\end{bmatrix}\end{aligned} \tag{6.8.87}$$

But we also have:

$$\begin{aligned}\mathrm{i}\vec{\sigma}\circ(\vec{a}\times\vec{b})&=\mathrm{i}\vec{\sigma}\circ\begin{pmatrix}a_yb_z-a_zb_y\\a_zb_x-a_xb_z\\a_xb_y-a_yb_x\end{pmatrix}\\ &=\mathrm{i}\begin{bmatrix}a_xb_y-a_yb_x&(a_yb_z-a_zb_y)-\mathrm{i}(a_zb_x-a_xb_z)\\(a_yb_z-a_zb_y)+\mathrm{i}(a_zb_x-a_xb_z)&(a_xb_y-a_yb_x)\end{bmatrix}\\ &=\begin{bmatrix}\mathrm{i}(b_ya_x-b_xa_y)&a_zb_x-b_za_x+\mathrm{i}(b_za_y-a_zb_y)\\b_za_x-a_zb_x+\mathrm{i}(b_za_y-b_ya_z)&\mathrm{i}(a_yb_x-a_xb_y)\end{bmatrix}\end{aligned} \tag{6.8.88}$$

So finally:

$$\boxed{(\vec{\sigma}\circ\vec{a})(\vec{\sigma}\circ\vec{b})=(\vec{a}\circ\vec{b})\mathbb{1}+\mathrm{i}\vec{\sigma}\circ(\vec{a}\times\vec{b})} \tag{6.8.89}$$

P6. We note that these matrices are also hermitian (let us recall that a Hermitian matrix is a transposed matrix followed by its complex conjugate according to what we saw in the section of Linear Algebra) such that:

$$\sigma_x = \sigma_x^\dagger \qquad \sigma_y = \sigma_y^\dagger \qquad \sigma_z = \sigma_z^\dagger \tag{6.8.90}$$

It is therefore in the language of quantum physics: Hermitian operators!!!

P7. The following traces can be derived using the commutation and anticommutation relations:

$$\begin{aligned}\operatorname{tr}(\sigma_j) &= 0\\ \operatorname{tr}(\sigma_j\sigma_k) &= 2\delta_{jk}\\ \operatorname{tr}(\sigma_j\sigma_k\sigma_\ell) &= 2\mathrm{i}\varepsilon_{jk\ell}\\ \operatorname{tr}(\sigma_j\sigma_k\sigma_\ell\sigma_m) &= 2\left(\delta_{jk}\delta_{\ell m} - \delta_{j\ell}\delta_{km} + \delta_{jm}\delta_{k\ell}\right)\end{aligned} \tag{6.8.91}$$

If the matrix $\sigma_0 = \mathbb{1}$ is also considered, these relationships become:

$$\begin{aligned}\operatorname{tr}(\sigma_\alpha) &= 2\delta_{0\alpha}\\ \operatorname{tr}(\sigma_\alpha\sigma_\beta) &= 2\delta_{\alpha\beta}\\ \operatorname{tr}(\sigma_\alpha\sigma_\beta\sigma_\gamma) &= 2\sum_{(\alpha\beta\gamma)}\delta_{\alpha\beta}\delta_{0\gamma} - 4\delta_{0\alpha}\delta_{0\beta}\delta_{0\gamma} + 2\mathrm{i}\varepsilon_{0\alpha\beta\gamma}\\ \operatorname{tr}(\sigma_\alpha\sigma_\beta\sigma_\gamma\sigma_\mu) &= 2\left(\delta_{\alpha\beta}\delta_{\gamma\mu} - \delta_{\alpha\gamma}\delta_{\beta\mu} + \delta_{\alpha\mu}\delta_{\beta\gamma}\right) + 4\left(\delta_{\alpha\gamma}\delta_{0\beta}\delta_{0\mu} + \delta_{\beta\mu}\delta_{0\alpha}\delta_{0\gamma}\right) - 8\delta_{0\alpha}\delta_{0\beta}\delta_{0\gamma}\delta_{0\mu} + 2\mathrm{i}\sum_{(\alpha\beta\gamma\mu)}\varepsilon_{0\alpha\beta\gamma}\delta_{0\mu}\end{aligned} \tag{6.8.92}$$

where Greek indices α, β, γ and μ assume values from $\{0, x, y, z\}$ and the notation $\sum_{(\alpha\ldots)}$ is used to denote the sum over the cyclic permutation of the included indices.

Let us now see what are the eigenvectors and eigenvalues of the Pauli matrices because this result is very useful for the section of Relativistic Quantum Physics and of Quantum Computing!

Let us recall that when a transformation (application of a matrix) act on a vector, it changes the direction of the vector except for specific matrices that have eigenvalues. In this case, the direction is conserved but not their length. This property is exploited in quantum mechanics (and not only as we will see in many other sections of this textbook).

Let us determine in a first time, the associated eigenvectors and eigenvalues (see section Linear Algebra page 1997) using the most common method:

The eigenvalues equation (see section Linear Algebra page 1998) is thus written:

$$\det(\sigma_x - \lambda I_n) = \det\begin{bmatrix}0-\lambda & 1\\ 1 & 0-\lambda\end{bmatrix} = 0 \tag{6.8.93}$$

Which gives us as characteristic equation:

$$\det(\sigma_x - \lambda I_n) = \lambda^2 - 1 = 0 \tag{6.8.94}$$

hence the eigenvalues $\lambda = \pm 1$. Which gives us the possibility to determine the eigenvectors as following:

$$\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix} = \begin{pmatrix}x\\ y\end{pmatrix} \Rightarrow \begin{pmatrix}y\\ x\end{pmatrix} = \lambda\begin{pmatrix}x\\ y\end{pmatrix} \tag{6.8.95}$$

Therefore for $\lambda=1$:

$$\begin{pmatrix} y \\ x \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \tag{6.8.96}$$

This impose that $y=x$. The eigenvector is therefore:

$$\begin{pmatrix} x \\ y=x \end{pmatrix} = x\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \forall x \tag{6.8.97}$$

whatever is the value of x.

Conclusion: The proper direction of the vector is conserved but not its length (norm) because it depends on the value of x.

For $\lambda=-1$:

$$\begin{pmatrix} y \\ x \end{pmatrix} = -1\begin{pmatrix} x \\ x \end{pmatrix} = \begin{pmatrix} -x \\ -y \end{pmatrix} \tag{6.8.98}$$

This impose that $y=-x$ and therefore that the eigenvector is equal to:

$$\begin{pmatrix} x \\ y=-x \end{pmatrix} = x\begin{pmatrix} 1 \\ -1 \end{pmatrix}, \forall x \tag{6.8.99}$$

The previous eigenvectors written with the Dirac formalism (see section Relativistic Quantum Physics page 4729) give for $\lambda=1$:

$$|v\rangle = x\begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} x \\ x \end{pmatrix} \tag{6.8.100}$$

with a norm (1 since we formalize to the unit):

$$\langle v|v\rangle = x^2+x^2=2x^2=1 \Rightarrow x=\pm\frac{1}{\sqrt{2}} \tag{6.8.101}$$

Remark

In the formalism of Dirac $\langle v|$ is the is named a "Bra" and $|v\rangle$ a "Ket".

This being only valid for components that are real numbers. The normalized eigenvector has therefore for expression:

$$|v\rangle = x = \pm\frac{1}{\sqrt{2}}\begin{pmatrix} 1 \\ 1 \end{pmatrix} \tag{6.8.102}$$

For $\lambda=-1$, we have:

$$|v\rangle = x\begin{pmatrix} 1 \\ -1 \end{pmatrix} = \begin{pmatrix} x \\ -x \end{pmatrix} \tag{6.8.103}$$

and:

$$\langle v|v\rangle = x^2+(-x)^2=2x^2=1 \Rightarrow x=\pm\frac{1}{\sqrt{2}} \tag{6.8.104}$$

and the normalized eigenvector has thus for expression:

$$|v\rangle=\pm\frac{1}{\sqrt{2}}\begin{pmatrix}1\\-1\end{pmatrix}\tag{6.8.105}$$

Let us now determine the eigenvectors and eigenvalues associated to σ_y by following the same procedure.

So we have for the eigenvalues:

$$\det(\sigma_y-\lambda I_n)=\det\begin{bmatrix}0-\lambda & -\mathrm{i}\\ \mathrm{i} & 0-\lambda\end{bmatrix}=0\Rightarrow\lambda^2-(-\mathrm{i}\cdot\mathrm{i})=0\Rightarrow\lambda=\pm 1\tag{6.8.106}$$

The eigenvectors are determined as following:

$$\begin{pmatrix}0 & -\mathrm{i}\\ \mathrm{i} & 0\end{pmatrix}=\begin{pmatrix}x\\y\end{pmatrix}=y\begin{pmatrix}x\\y\end{pmatrix}\Rightarrow\begin{pmatrix}-\mathrm{i}y\\ \mathrm{i}x\end{pmatrix}=\lambda\begin{pmatrix}x\\y\end{pmatrix}\tag{6.8.107}$$

and therefore for $\lambda=1$:

$$\begin{pmatrix}-\mathrm{i}y\\ \mathrm{i}x\end{pmatrix}=\begin{pmatrix}x\\y\end{pmatrix}\Rightarrow x=\frac{y}{\mathrm{i}}=-\mathrm{i}y\tag{6.8.108}$$

The eigenvector is therefore:

$$\begin{pmatrix}x\\ y=\mathrm{i}x\end{pmatrix}=\begin{pmatrix}x\\ \mathrm{i}x\end{pmatrix}=x\begin{pmatrix}1\\ \mathrm{i}\end{pmatrix},\forall x\tag{6.8.109}$$

The associated norm:

$$\langle v|v\rangle=x^2(1,-\mathrm{i})\begin{pmatrix}1\\1\end{pmatrix}=x^2\left[1+(-\mathrm{i}\cdot\mathrm{i})\right]=2x^2=1\Rightarrow x=\pm\frac{1}{\sqrt{2}}\tag{6.8.110}$$

The normalized vector is therefore expressed as:

$$|v\rangle=x=\pm\frac{1}{\sqrt{2}}\begin{pmatrix}1\\ \mathrm{i}\end{pmatrix}\tag{6.8.111}$$

For $\lambda=-1$:

$$\left(\begin{array}{c}-\mathrm{i}y\\ \mathrm{i}x\end{array}\right)=-\left(\begin{array}{c}x\\ y\end{array}\right)=\left(\begin{array}{c}-x\\ -y\end{array}\right)\Rightarrow y=\frac{1}{\mathrm{i}}x=-\mathrm{i}x\tag{6.8.112}$$

The eigenvector is therefore:

$$\left(\begin{array}{c}x\\ y=-\mathrm{i}x\end{array}\right)=\left(\begin{array}{c}x\\ -\mathrm{i}x\end{array}\right)=x\left(\begin{array}{c}1\\ -\mathrm{i}\end{array}\right),\forall x\tag{6.8.113}$$

The associated norm:

$$\langle v\,|\,v\rangle=x^2[1,\mathrm{i}]\left(\begin{array}{c}1\\ -\mathrm{i}\end{array}\right)=x^2\left[1^2+(-\mathrm{i}\cdot\mathrm{i})\right]=2x^2=1\Rightarrow x=\pm\frac{1}{\sqrt{2}}\tag{6.8.114}$$

The normalized vector has then for expression:

$$|v\rangle = x = \frac{\pm 1}{\sqrt{2}}\begin{pmatrix} 1 \\ -\mathrm{i} \end{pmatrix} \tag{6.8.115}$$

Let us now determine the eigenvectors and eigenvalues associated to σ_z by doing the same again.

We have therefore:

$$\begin{aligned} &\det(\sigma_z - \lambda I_n) = \det\begin{bmatrix} 1-\lambda & 0 \\ 0 & -1-\lambda \end{bmatrix} = (1-\lambda)(-1-\lambda) = -(\lambda^2 - 1) = 0 \\ &\lambda^2 - 1 = 0 \Rightarrow \lambda = \pm 1 \end{aligned} \tag{6.8.116}$$

The eigenvectors are then for $\lambda = 1$:

$$\begin{pmatrix} x \\ -y \end{pmatrix} = \begin{pmatrix} x \\ y \end{pmatrix} \tag{6.8.117}$$

Which makes problem to us for say anything ... the only possibility is to choose $y = 0$ and therefore:

$$\begin{pmatrix} x \\ 0 \end{pmatrix} = x\begin{pmatrix} 1 \\ 0 \end{pmatrix} \tag{6.8.118}$$

and the associated norm:

$$\langle v|v\rangle = x^2 + 0^2 = x^2 = 1 \Rightarrow x = \pm 1 \tag{6.8.119}$$

The normalized vector has then for expression:

$$|v\rangle = \pm\begin{pmatrix} 1 \\ 0 \end{pmatrix} \tag{6.8.120}$$

and for $\lambda = -1$ we will have the same choice to do by choosing this time $x = 0$ and therefore:

$$|v\rangle = \begin{pmatrix} 0 \\ -y \end{pmatrix} = -y\begin{pmatrix} 0 \\ 1 \end{pmatrix} \tag{6.8.121}$$

hence the associated norm:

$$\langle v|v\rangle = 0^2 + (-y)^2 = y^2 = 1 \Rightarrow y = \pm 1 \tag{6.8.122}$$

The normalized eigenvector has then for expression:

$$|v\rangle = \pm\begin{pmatrix} 0 \\ 1 \end{pmatrix} \tag{6.8.123}$$

Therefore the normalized eigenvectors of σ_z are on the directions of the Cartesian coordinate axes. It is for this particular reason that the eigenvectors of σ_z are denoted in quantum computing by:

$$|+\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \qquad |-\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \tag{6.8.124}$$

and the reader should also know that we write also:

$$\sigma_z|\pm\rangle = \sigma_3|\pm\rangle = \pm|\pm\rangle \tag{6.8.125}$$

7.1. Functional Analysis

FUNCTIONAL ANALYSIS is the branch of mathematics and specifically of the analysis that is related to the study of function spaces. It takes its historical roots E as neutral "additive" elementin the study of transformations such as the Fourier transform and in the study of differential equations and integrals. As such it encompasses so many areas that it is difficult to justify that it be a section of this textbook because it is rather a field of study. Moreover, it is because of this difficulty to accurately identify the area it covers that the reader will find the Fundamental Theorem of Calculus in the chapter of Integral and Differential Calculus rather than here...

Why do we use the term "analysis" in the particular case of functions? The reason lies in the historical study of various phenomena of nature and resolution of various technical problems and therefore mathematics, which often lead us to consider the variation of a parameter correlated with the variation of another or several other variables. To study these variations, many tools are available to each of us:

- The engineer, for example, frequently use charts (in cartesian, polar or logarithmic coordinate system... concepts which are discussed further in more detail) to determine the mathematical relations (or "law") linking variables between them. Certainly, this kind of method is (sometimes ...) aesthetic but students know well how it is sometimes painful to transcribe measures points on a sheet of paper or on a computer and consultants know how dangerous can be a chart when not build in a scientific way. This is unfortunately a necessary step (but should avoid an abusive usage) to understand how our predecessors worked and got the results that help us today in our advances in theoretical physics.
- The mathematician and theoretical physicist usually hate to use the paper-pencil-scrawl methods. Nevertheless, the role of the mathematician or physicist is to develop new theories with mathematical axioms or principles which should require no usage of graphical representation nor access to experimental measures that are often attached to it.

Remark

Before starting to read what follows, it may be useful to remind the reader that the definition of the concept of "function" (and the basic properties thereto) is given in the section on Set Theory at page 403.

Function analysis is also strongly linked to Vector Calculus (and not only...). Thus for people who want to increase their knowledge about the fundamentals of function analysis we strongly recommend the reader to have a look to the Vector Calculus section at page 1794.

7.1.1 Representations

We will see in what follows, firstly, how to represent different values related by tables and charts (yes! We must because it helps to understand more complicated stuff) and secondly how to mathematically analyse the properties of these representations only by using abstract mathematical tools.

Definition (#7.1.267): A function is named "univalent function" or "unary function" if the number of its arguments (parameters or variables) is equal to one. In the case of a function of two arguments, we speak about a "bivalent function" or "bivalent function", etc. Formally a function is n-ary if:

$$f: A_1 \times A_2 \times \ldots \times A_n \mapsto B \tag{7.1.1}$$

7.1.1.1 Tabular Representations

Among the possible visual representation of functions, the most intuitive and the oldest is the one where we have in the columns or the rows of a table in an orderly way the values of the independent variable $x_1, x_2, \ldots, x_n$ and the corresponding values, namely the "transformed variables" of the function $y_1, y_2, \ldots, y_n$ in another column or aligned row:

x	$y = f(x)$
x_1	$y_1 = f(x_1)$
x_2	$y_2 = f(x_2)$
...	...
x_n	$y_n = f(x_n)$

In the expression:

$$y = f(a_1, a_2, \ldots, a_n) \tag{7.1.2}$$

we say that the $a_1, a_2, \ldots, a_n$ are the "arguments" of f and such a table where every variable/argument is stored in a column is named a "long format table".

Such are, for example, tables of trigonometric functions, logarithmic tables, etc. and during the experimental study of certain phenomena tables which express the existing functional dependence between the measured physical quantities such as the readings of the temperature of the air stored in a meteorological station during one day.

Of course, this concept can be generalized to any multivariate function regardless its definition domain.

However, this method is laborious and does not permit to directly see the behaviour of the function and therefore a simple and attractive visual analysis of its qualitative properties for humans. It still has the advantage of not requiring any special tools or advanced mathematics and easily tractable by computers[1].

Another type of tabular representation are "crossed-tables", also named "pivot-tables" or "wide format",where we have categorical/ordinal variables names in the first column AND in the first row:

	Express Passenger	**Ordinary Passenger**	**Total**
Arriva Trains Wales	3,079	830	3,909
Cross Country	22,865	63	22,928
London Midland	14,487	33,792	48,279
Virgin Trains	8,594		8,594
Total	49,025	34,685	83,710

And here another kind of such table but with multiple categorical column variables (the same can be done with by having multiple row variables):

	Express Passenger		**Ordinary Passenger**		**Total**	
	# Trains	**Max. Speed**	**# Trains**	**Max. Speed**	**# Trains**	**Max. Speed**
Arriva Trains Wales	3,079	90	830	90	3,909	90
Cross Country	22,865	125	63	100	22,928	125
London Midland	14,487	110	33,792	100	48,279	110
Virgin Trains	85,94	125			8,594	125
Total	49,025	125	34,685	100	83,710	125

We can find more complex versions of the above example, like the generic multi-dimensional crossed-table with subtotals visible at page 1045.

When we have a collection of repeated observations of the same subjects, taken from a given population, over some time, we speak then of "longitudinal table". Typically (the years are given based on the holocene calendar):

	January 12001	**February 12001**	**Total**
Arriva Trains Wales	3,079	830	3,909
Cross Country	22,865	63	22,928
London Midland	14,487	33,792	48,279
Virgin Trains	8,594		8,594
Total	49,025	34,685	83,710

We can have obviously also "longitudinal crossed tables", also named "longitudinal pivot tables":

---

[1] According to the US Open Data Act. of January 12019 (holocene calendar): «*machine readable data is a format that can be easily processed by a computer without human intervention while ensuring no semantic meaning is lost.*»

	January 12001		February 12001		Total	
	# Trains	Max. Speed	# Trains	Max. Speed	# Trains	Max. Speed
Arriva Trains Wales	3, 079	90	830	90	3, 909	90
Cross Country	22, 865	125	63	100	22, 928	125
London Midland	14, 487	110	33, 792	100	48, 279	110
Virgin Trains	8, 594	125			8, 594	125
Total	49, 025	125	34, 685	100	83, 710	125

But all crossed and longitudinal tables (i.e. "wide formats") above are not tractable in the field of science and engineering and therefore should never be used to store datas!!! So it is common to unpivot the columns to get a normalized version of the datas (including the dates at the ISO 8601 format and removing the totals and subtotals and all fancy formatting on numerical values). The previous table, for example, will once unpivoted become the following "long format" table (i.e. "flat table"):

Type	Date	# Trains	Max Speed
Arriva Trains Wales	12001-01-31	3079	90
Arriva Trains Wales	12001-02-28	830	90
Cross Country	12001-01-31	22865	125
Cross Country	12001-02-28	63	100
London Midland	12001-01-31	14487	110
London Midland	12001-02-28	33792	100
Virgin Trains	12001-01-31	8594	125
Virgin Trains	12001-02-28		

Table 7.1: **Example of transformation of a wide crossed table to a long format table (i.e. flat table)**

Remark

Even if the above table is tractable in the field of Science and Engineering (also of Business), it is however absolutely not optimal in a Computer Science storage point of view! The above table should be fractioned as a fact table in a snowflake schema (or star schema) having only relationships with dimension tables. For more see information about these concepts, see [126].

We name "Complete Disjunctive Table" (CDT), the matrix of size $n \times p$ defined by (see example just below):

$$K_{IJ} = k_{ij} \tag{7.1.3}$$

where:

$$k_{ij} = \begin{cases} 1 & \text{if the individual } i \text{ has the modality } j \\ 0 & \text{otherwise} \end{cases} \tag{7.1.4}$$

This is a fundamental tool (i.e. step) in the calculation for Multiple Correspondence Analysis (see section Numerical Methods page ??).

✍**Example:**

Here is an example of complete disjunctive table. From a data table with two category variables, with respectively two and three modalities, a complete disjunctive table is created containing five dummy variables:

	Q1	Q2
Obs. 1	A	C
Obs. 2	B	D
Obs. 3	B	E
Obs. 4	A	D

The complete disjunctive table K_{IJ} is then given by:

	Q1 $-A$	Q1 $-B$	Q2 $-C$	Q2 $-D$	Q2 $-E$
Obs. 1	1	0	1	0	0
Obs. 2	0	1	0	1	0
Obs. 3	0	1	0	0	1
Obs. 4	1	0	0	1	0

Now that the reader has seen the simple definition and an example, more formally let us assume that we have at our disposal $m>2$ qualitative variables $x^1,\ldots,x^m$ and that we observe n individuals, then for each $k\in\{1,\ldots,m\}$, the variable x^k can take c_k distinct values denoted by $1,\ldots,c_k$ and c denotes the total number of modes:

$$c=\sum_{k=1}^{m}c_k \tag{7.1.5}$$

For each $i\in\{1,\ldots,n\}$, $x_i^k\in\{1,\ldots,c_k\}$ is the value of the variable x^k observed for the i-th individual.

For each mode of each variable, we consider the associated indicator vector, i.e. for each $k\in\{1,\ldots,m\}$ and each $\ell\in\{1,\ldots,c_k\}$:

$$\mathbb{I}_{m\ell}=\begin{pmatrix}\mathbf{1}_{x_1^k=\ell}\\ \vdots\\ \mathbf{1}_{x_n^k=\ell}\end{pmatrix}\in\{0,1\}^n \tag{7.1.6}$$

If we put these vectors in the columns of a matrix T of size $n\times c$, you we get the complete disjunctive table:

$$K_{IJ}=[\mathbb{I}_{11}\cdots\mathbb{I}_{1c_1}\cdots\mathbb{I}_{21}\cdots\mathbb{I}_{2c_2}\cdots\mathbb{I}_{m1}\cdots\mathbb{I}_{mc_m}] \tag{7.1.7}$$

We name "Burt table" the matrix of size $p\times p$ defined by (see example just below):

$$B=b_{jj'} \tag{7.1.8}$$

where $b_{jj'}=\sum_{i=1}^{n}k_{ij}k_{ij'}$ (the k_{ij} are the components of the complete disjunctive table defined just above).

Therefore the Burt table can also be defined by K_{IJ}:

$$B=\{b_{jj'}\}_{jj'}=K_{IJ}^TK_{IJ}=\sum_{i=1}^{n}k_{ij}k_{ij'} \tag{7.1.9}$$

✍**Example:**

Using the previous example, we then get:

$$B=\{b_{jj'}\}_{jj'}=K_{IJ}^TK_{IJ}=\begin{bmatrix}2&0&1&1&0\\0&2&0&1&1\\1&0&1&0&0\\1&1&0&2&0\\0&1&0&0&1\end{bmatrix} \tag{7.1.10}$$

It is possible to see $B=\{b_{jj'}\}_{1\leqslant j,j'\leqslant p}$ as a matrix of $p\times p$ blocks such that:

- If $p\neq p'$ then $b_{jj'}$ is the contingency table relative to the variables x^j et $x^{j'}$.
- If $j=j'$ then b_{jj} is a diagonal matrix that contains the marginal totals of the variable x^j denoted by $n_1^j,\ldots,n_{c_j}^j$

✍**Example:**

Consider the following table:

	Gender (G)	Color (C)	Age (A)
1	Woman	Red	20
2	Man	Blue	25
3	Man	Green	30
4	Woman	Red	35

The corresponding complete disjunctive table K_{IJ} is therefore:

	G.Woman	G.Men	C.Blue	C.Red	C.Green	A.20	A.25	A.30	A.35
1	1	0	0	1	0	1	0	0	0
2	0	1	1	0	0	0	1	0	0
3	0	1	0	0	1	0	0	1	0
4	1	0	0	1	0	0	0	0	1

and the corresponding Burt table B:

	G.Woman	G.Man	C.Blue	C.Red	C.Green	A.20	A.25	A.30	A.35
G.Woman	2	0	0	2	0	1	0	0	1
G.Man	0	2	1	0	1	0	1	1	0
C.Blue	0	1	1	0	0	0	1	0	0
C.Red	2	0	0	2	0	1	0	0	1
C.Green	0	1	0	0	1	0	0	1	0
A.20	1	0	0	1	0	1	0	0	0
A.25	0	1	1	0	0	0	1	0	0
A.30	0	1	0	0	1	0	0	1	0
A.35	1	0	0	1	0	0	0	0	1

We name "Complete Disjunctive Table" (CDT), the matrix of size $n \times p$ defined by (see example just below):

$$K_{IJ} = k_{ij} \tag{7.1.11}$$

where:

$$k_{ij} = \begin{cases} 1 & \text{if the individual } i \text{ has the modality } j \\ 0 & \text{otherwise} \end{cases} \tag{7.1.12}$$

This is a fundamental tool (i.e. step) in the calculation for Multiple Correspondence Analysis (see section Numerical Methods page **??**).

✍**Example:**

Here is an example of complete disjunctive table. From a data table with two category variables, with respectively two and three modalities, a complete disjunctive table is created containing five dummy variables:

	Q1	Q2
Obs. 1	A	C
Obs. 2	B	D
Obs. 3	B	E
Obs. 4	A	D

The complete disjunctive table K_{IJ} is then given by:

	Q1 – A	Q1 – B	Q2 – C	Q2 – D	Q2 – E
Obs. 1	1	0	1	0	0
Obs. 2	0	1	0	1	0
Obs. 3	0	1	0	0	1
Obs. 4	1	0	0	1	0

7.1.1.2 Graphical Representations

The natural, relative, real or purely imaginary numbers (see section Numbers page 215) can all be represented as simply by points on a numerical infinite axis (straight line).

To this purpose, we choose on this axis:

1. A point O named "origin"
2. A positive direction, that we indicate by a horizontal arrow
3. A unit of measure (usually represented by small vertical lines: the "graduation")

Such that:

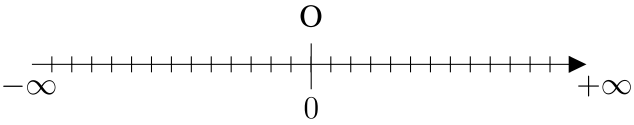

Figure 7.1: Typical representation example of an oriented infinite axis with origin

In most cases we put (traditionally) the axis horizontally and choose the direction from left to right (at least when there is only one axis...).

> **Remark**
>
> The point (letter) **O**, frequently represents the number zero in mathematics but we might very well choose to put the origin elsewhere. For example, in physics, the point **O** is often positioned at the location of the centroid of a system.

It is obvious that the fact that the sets of numbers that we discussed in the section Numbers are ordered implies that every number is represented by a single point on this axis. Thus, two distinct real numbers correspond two different points on the axis.

Thus, there is a correspondence between all numbers and all the points of the axis (in the case of real or complex numbers, it corresponds not a number to each graduation, but a number at each point of the axis!). Thus, each number represents a point or a unique graduation and back to each point or graduation is a single number which is the image.

7.1.1.2.1 2D representations

There are besides the one dimensional representations, other of higher dimensions (phew!...) like the "planar representation" that allow us to draw much more than simple points on a one-dimensional straight line but functions of one variable (but also points!). Let's see what this is and looks like:

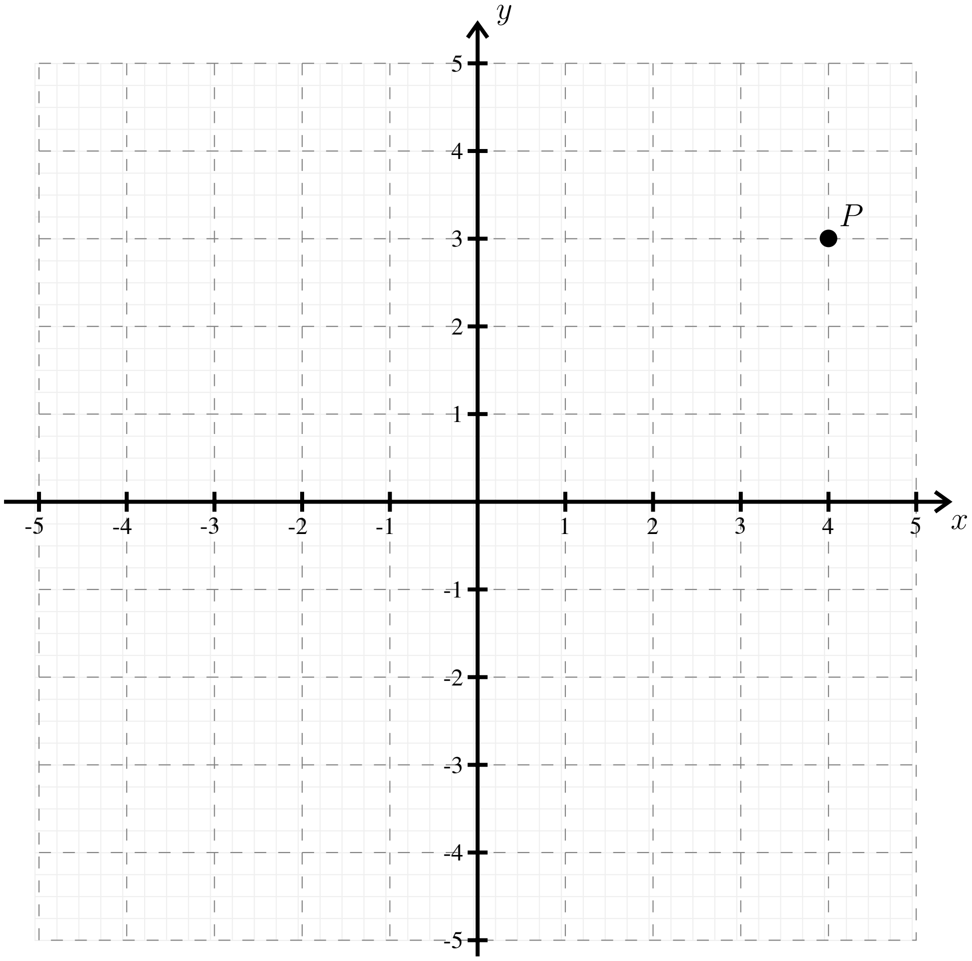

Figure 7.2: **Position of a point in a cartesian plane**

In the above figure we have added two graduation that helps us to identify uniquely the position of the point P given by $P(x,y)=P(+4,+3)=P(4,3)$. We then speak of "cartesian coordinates of a point".

In single-variable calculus, the functions that one encounters are functions of a variable (usually x or t) that varies over some subset of the real number line (which we denote by $\mathbb{R}$). For such a function, say, $y=f(x)$, the graph of the function f consists of the points:

$$(x,y)=(x,f(x)) \tag{7.1.13}$$

These points lie in the Euclidean plane, which, in the Cartesian or rectangular coordinate system, consists of all ordered pairs of real numbers (a,b). We use the word "Euclidean" to denote a system in which all the usual rules of Euclidean geometry hold (see section Euclidean Geometry page 2631). We denote the Euclidean plane by $\mathbb{R}^2$ where the exponent "2" represents the number of dimensions of the plane.

Thus we can for each of a variable x on a horizontal axis, named commonly "x-axis" match a value y through a function f such that:

$$y = f(x) \tag{7.1.14}$$

plotted on a vertical axis, named commonly the "y-axis" which passes through the junction defined by the origin O such tat (arbitrary example):

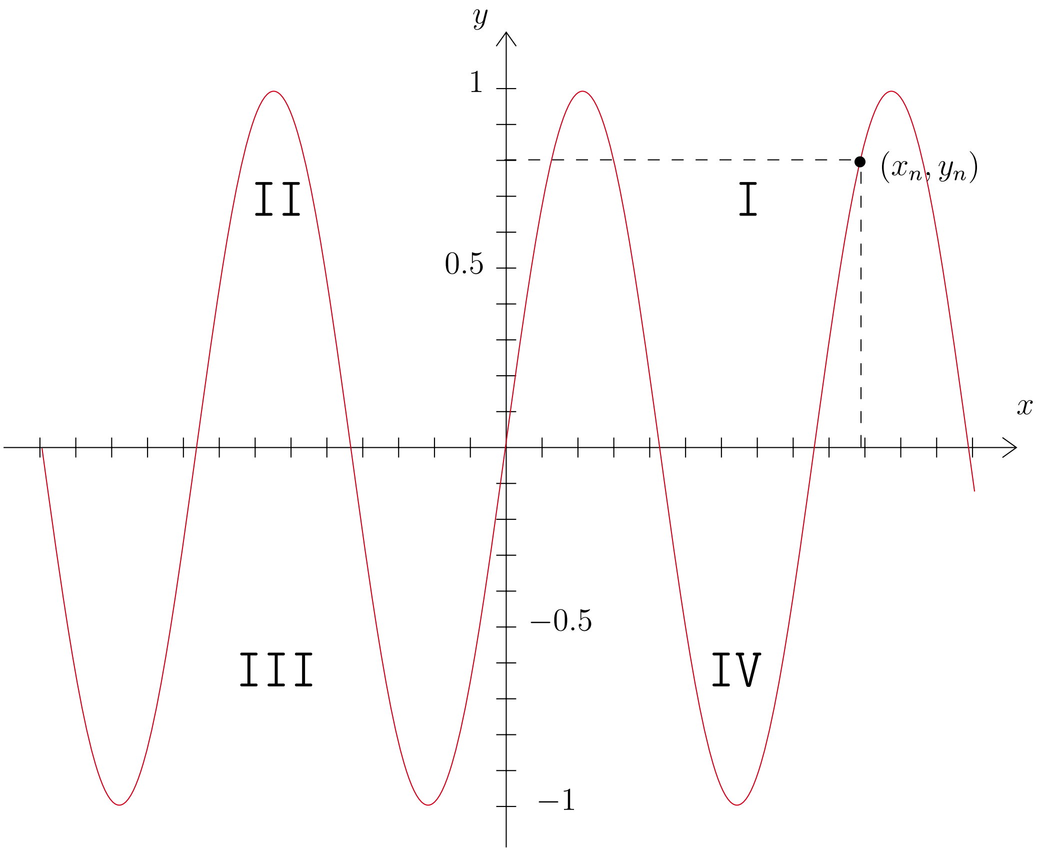

Figure 7.3: **Typical example of a planar representation with orthogonal axes, origin O and the 4 quadrants**

All points of the plane (that latter being denoted with the variations XOY, XY or xOy, Oxy, xy) have for "abscissa" traditionally the x-values corresponding to the independent variable (horizontal axes by tradition) of the function and for "ordinate" the corresponding value of the function (vertical axes by tradition). All these generated what is named the "planar graph" of the function. If there is no confusion, we just say "graph".

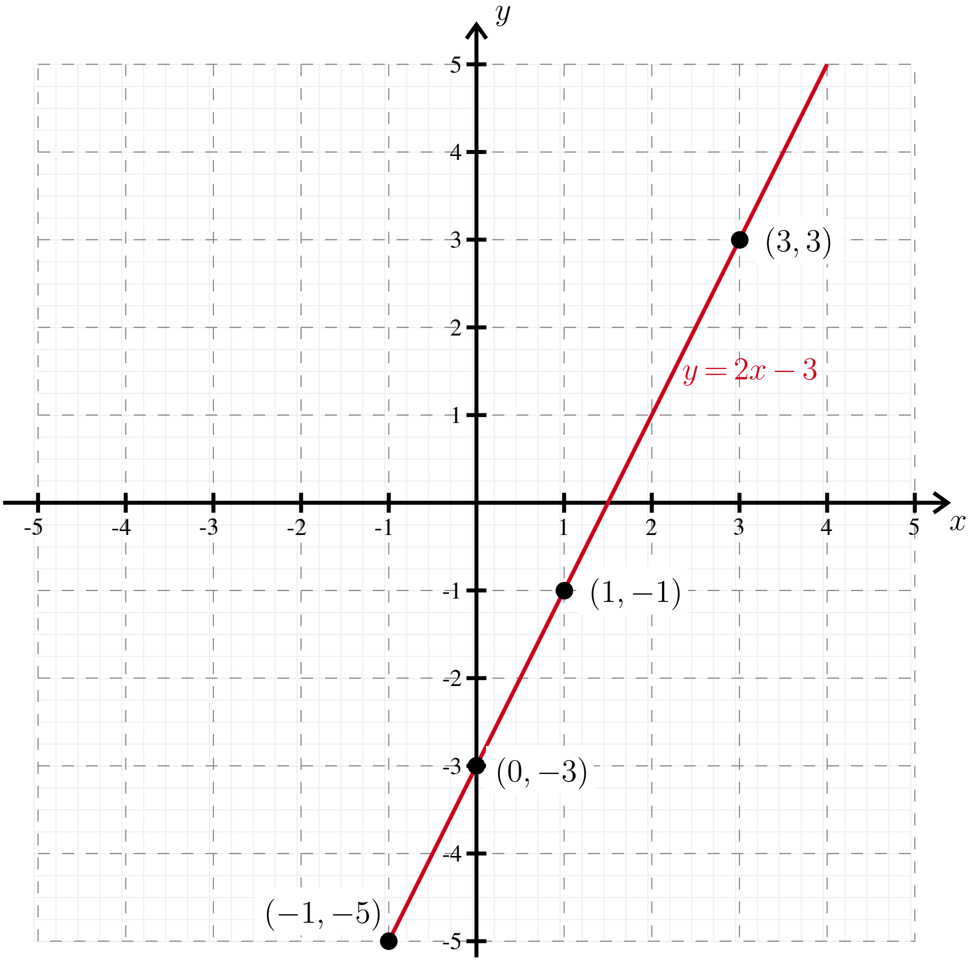
Figure 7.4: **Vocabulary planar graph**

An interesting detailed example for middle schools students that may help is the planar representation of the following line equation:

$$y = f(x) = 2x - 3 \quad (7.1.15)$$

That gives in the range $x \in [-3.3, +3.3]$ the following graph:



with its equivalent tabular representation for some arbitrary chosen points:

x	$2x-3$	**Point** $(x,2x-3)$
-1	$2\cdot(-1)-3=-5$	$(-1,-5)$
0	$2\cdot(0)-3=-3$	$(-1,-5)$
$+1$	$2\cdot(+1)-3=-1$	$(-1,-5)$
$+3$	$2\cdot(+3)-3=+3$	$(-1,-5)$

Table 7.2: **Values and corresponding transformed variables**

In the case of representation by a rectangular coordinate system (cartesian, polar or logarithmic) as the figure above, we can see that the entire coordinate plane is divided into four areas that by tradition we name "quadrants" as already mentioned just earlier.

> **Remark**
>
> When we wish to highlight a particular point on the graph representing the function, we draw most of time a small round as presented in the prior-previous figure for the point of coordinates (x_n,y_n).

Another classic case of plane graph representation known by a large number of students is the plot of polynomials (see section Calculus page 1368) with real coefficients or trigonometric functions (see section Trigonometry page 2503).

Indeed, to solve polynomial equations of the second degree (see section Calculus page 1382), it is common in small classes that the teacher asks his students in addition to give an algebraic expression of the roots of:

$$y=f(x)=ax^2+bx+c=0 \tag{7.1.16}$$

given by for recall (see section Calculus page 1383 for the proof):

$$x_{1,2}=\frac{-b\pm\sqrt{b^2-4ac}}{2a} \tag{7.1.17}$$

a graphics resolution where the two roots (in the case where there are two distinct real roots) are given by the intersection of the parabola with the x-axis (of course, if the equation has no solution, there are no intersections...):

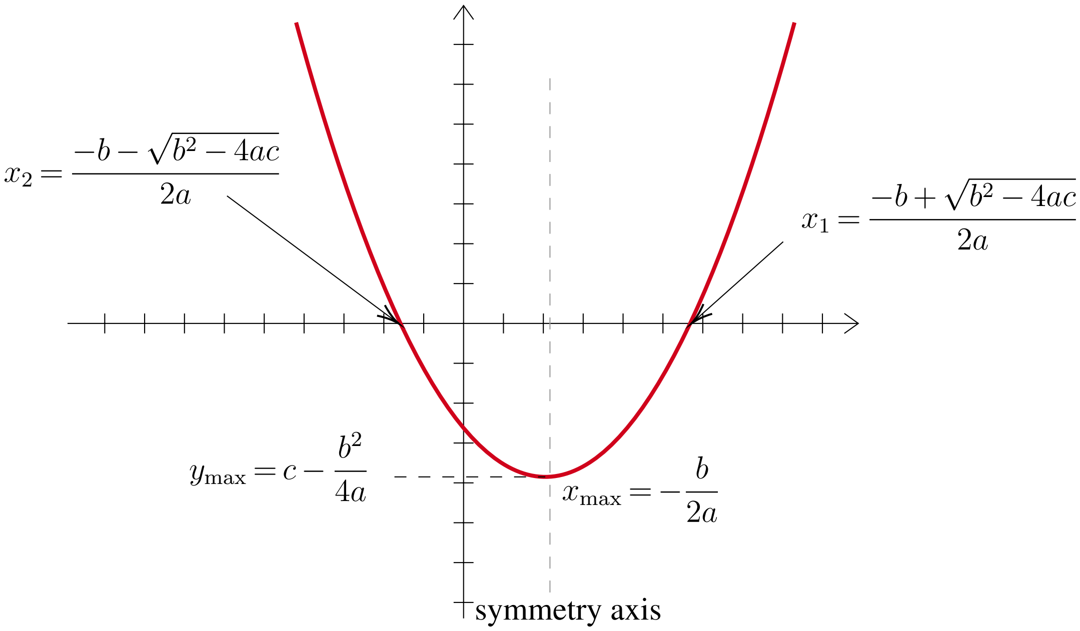


Figure 7.5: **Representation of roots on a planar graph**

The graphical representation can be generalized to polynomial equations of the 3rd, 4th and 5th degree (we will prove much further, using Galois theory that it is not possible to get a general algebraic expression of the roots of a polynomial equation of the 5th degree and higher).

There is another well-known and interesting example of special planar graph because when most young people think that after high-school they will never do maths again, in Switzerland many employees are faced to calculate in spreadsheet softwares (like Microsoft® Excel®) what we name the "coordinate wage" (CW) that is a "step-wise function" defined in year 12013 (holocene calendar) by the swiss government as:

$$\text{CW}:=\begin{cases} 0 & S<\frac{3}{4}R \\ \frac{R}{8} & \frac{3}{4}R\leq S<R \\ S-\frac{7}{8}R & R<S<3R \\ \frac{17}{8}R & 3R\leq S \end{cases} \tag{7.1.18}$$

where R is a minimal value defined also by the swiss government as being equal to $25,800.-$ in 12013 (holocene calendar) and the wage is denoted by the letter S (for **S**alary).

When we plot such a stepwise function with for example Maple™ 4.00b we get:

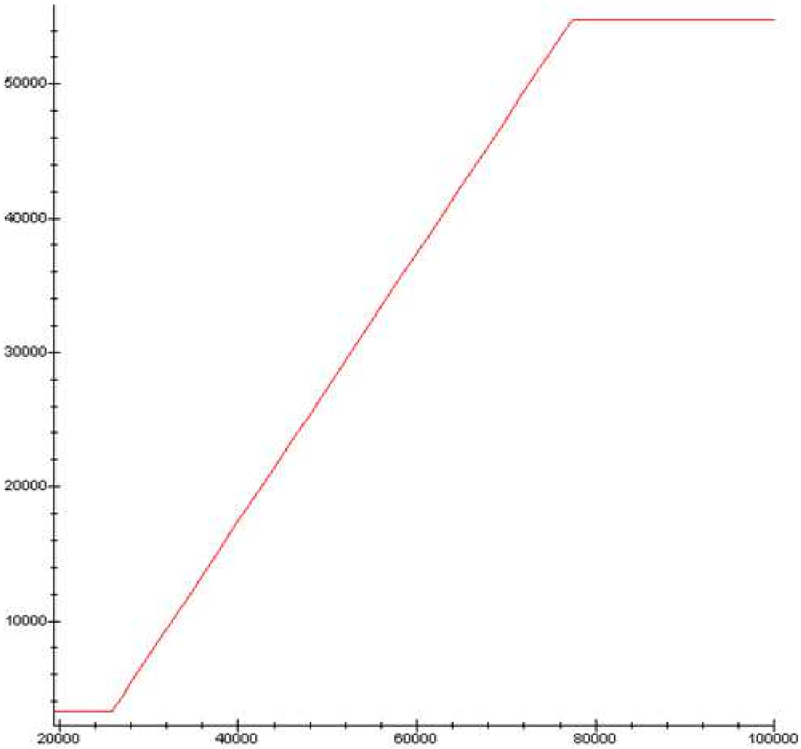

Figure 7.6: Example of step-wise function for swiss coordinate wage in Maple™ 4.00b

And therefore it is obvious thanks to this chart representation that the previous definition can be simplified as:

$$\text{CW} := \begin{cases} 0 & S < \dfrac{3}{4}R \\ \min\left\{\max\left[\dfrac{R}{8}, S - \dfrac{7}{8}R\right], \dfrac{17}{8}R\right\} & S \geq \dfrac{3}{4}R \end{cases} \tag{7.1.19}$$

That is much easier to write in any spreadsheet software or also in Maple™ 4.00b:

```
>R:=258000;
>plot(min(max(R/8,S-7/8*R),17/8*R,S=3/4*R..100000);
```

Also, graphs are as we know powerful qualitative tools in the field of statistics (see section Statistics page 542) but also of data mining (see section Numerical Methods page 6768) as a starting point for data analysis (histograms, cheese, box plots, radar, scatter plots, etc.). The assumptions and ideas that are generated by graphical analysis can be investigated with advanced statistical tools (for a few hundred of examples see the `R` or MATLAB® softwares companion book).

Below for example, a graph (histogram) taken from the Industrial Engineering section that is very common in the field of statistics and project management in the global industry:

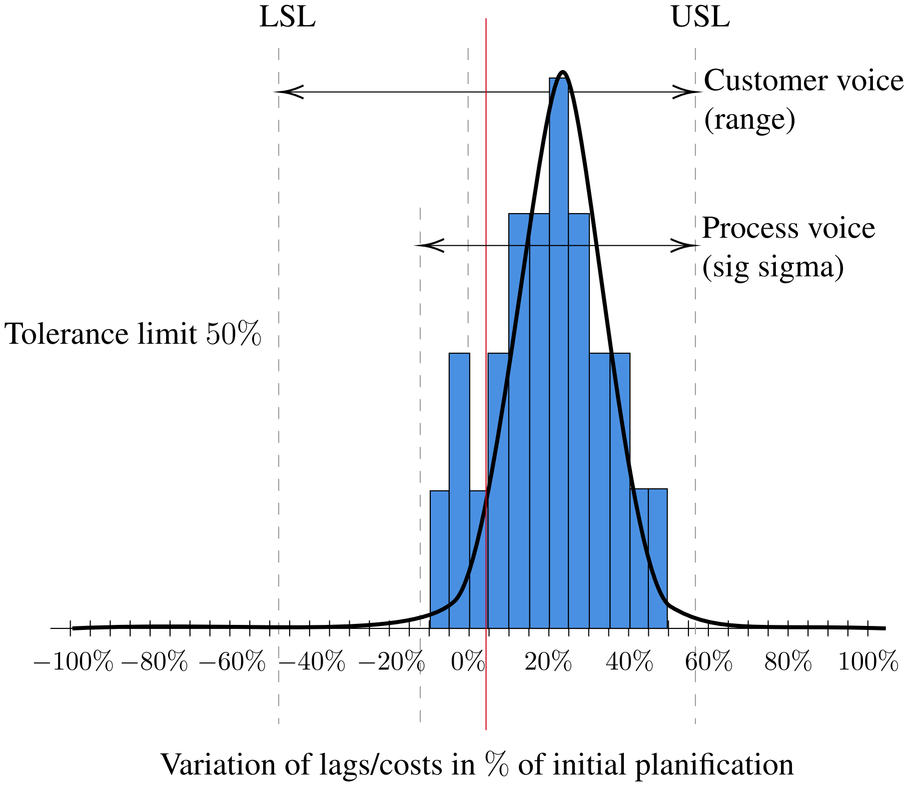

Figure 7.7: **Example of typical histogram in engineering companies (Six Sigma)**

Histograms allow to observe distributions and determine qualitatively if it fits a particular theoretical model.

Graphics can also be used to observe changes over time (time series, control charts, residual analysis, etc.):

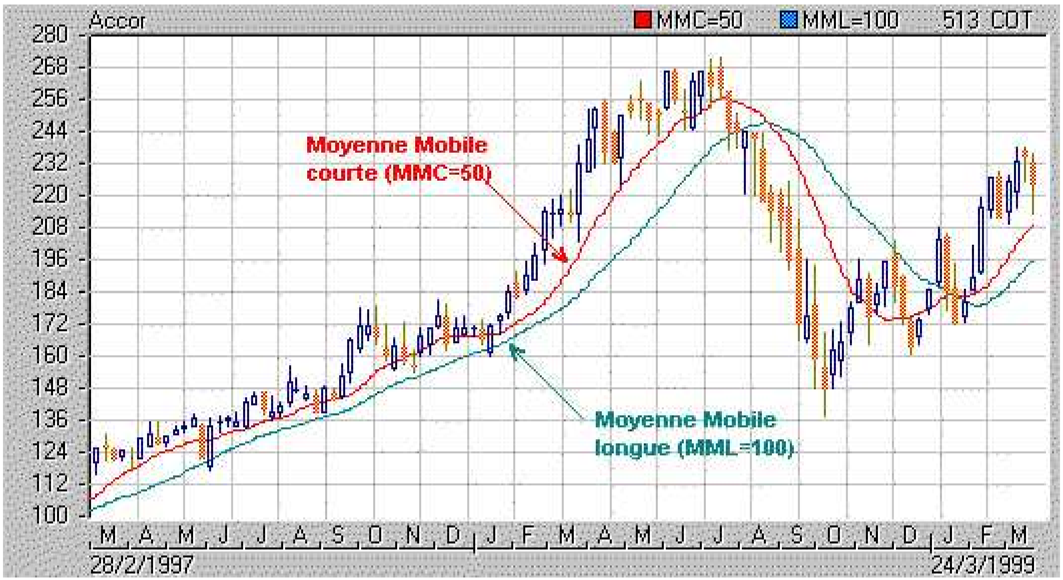

Figure 7.8: **Example of OHLC (candlestick plot) time series with moving averages in financial trading**

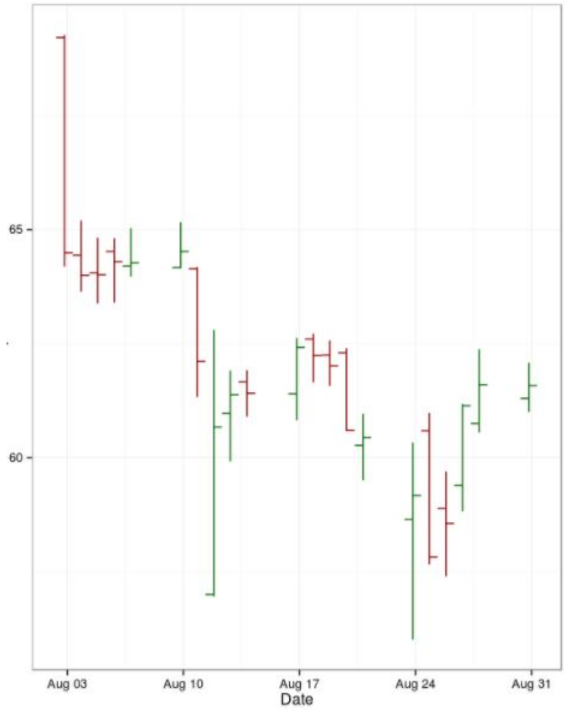
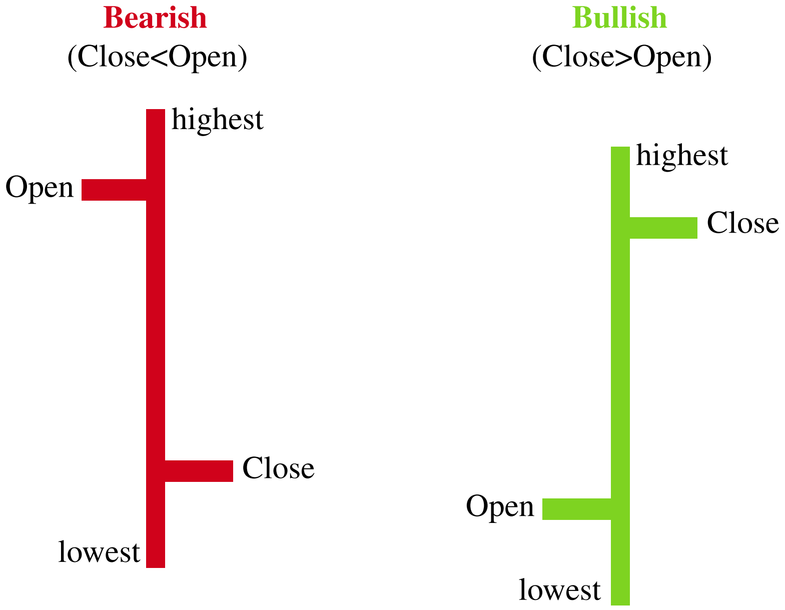
or another type of OHLC (Open-High-Low-Close) trading plot:



There are different rules for the colors of an OHLC plot! We can first define a color depending if the close price is lower than the open price of the same symbol/candlestick (the open price is always on the left and the closure price always on the right):



Bearish
(Close<Open)
highest
Open
Close
lowest
Bullish
(Close>Open)
highest
Close
Open
lowest

A common question related to this chart is: *Why doesn't a candlestick open when another one closes?*

This is because the close price is defined by the last tick of clock to arrive before the end of the candles time period, this may be several seconds before the end of the candles time period. The next candles open price is generated by the first tick of the clock to arrive after the beginning of its time period, this tick will reflect a change in price since the tick that generated the close price of the last candle, this first tick of the new candle may be several seconds after the beginning of the candles time period.

And still many other charts... that we have already seen and others that we will see throughout the pages of this textbook.

7.1.1.2.2 3D representations

Of course, in the case of a trivalent function (three-dimensional), that is to say a parameter which depends on two other, the idea is the same as for 2D except that the number of quadrants doubles:

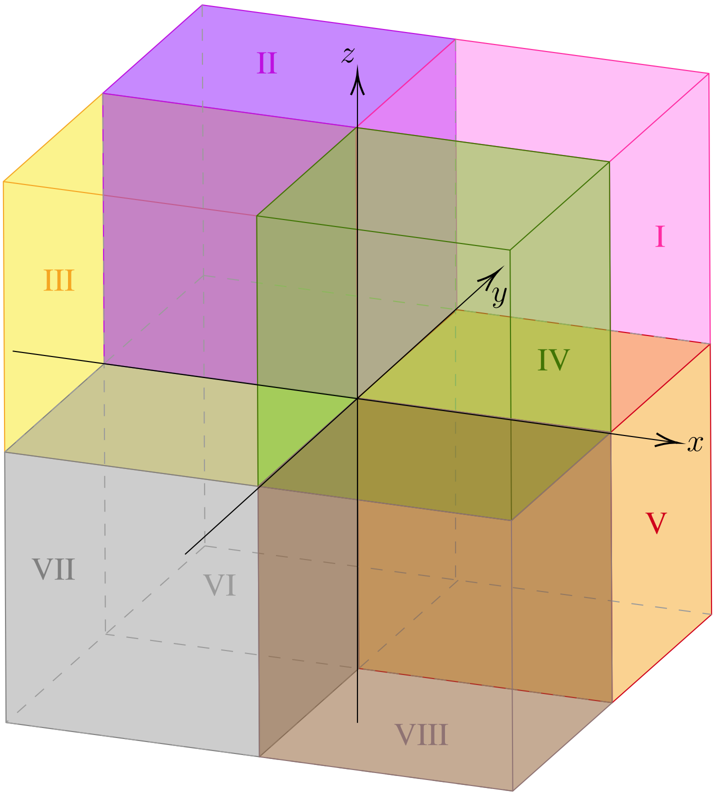


Figure 7.9: **Quadrants in a 3D orthogonal system (source: Wikipedia)**

This 3D method of representation and analysis of a trivalent function was time consuming at the beginning of the 120th century (holocene calendar) but with the help of computers in the end of the 120th century this time consuming problem was almost solved...

In 3D functional analysis, we will deal with functions of two or three variables (usually x, y, z, respectively). The graph of the arrow of coordinates $(x, y, z) = (x, y, f(x, y))$, lies in the Euclidean space. Since the Euclidean space can be 3-dimensional (and more or less for sure!), we denote it by $\mathbb{R}^3$.

Euclidean space has three mutually perpendicular coordinate axes (x, y and z), and three mutually perpendicular coordinate planes: the xy-plane, yz-plane and xz-plane.

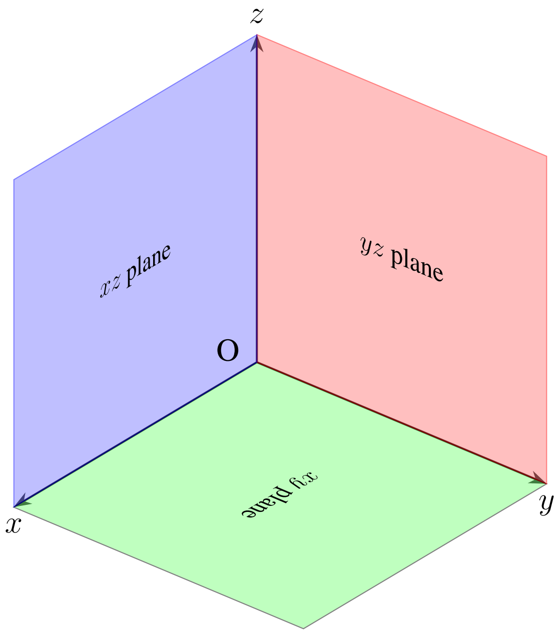

Figure 7.10: **Mutually perpendicular planes in $\mathbb{R}^3$**

The coordinate system shown above is known as a right-handed coordinate system, because it is possible, using the right hand, to point the index finger in the positive direction of the x-axis, the middle finger in the positive direction of the y-axis, and the thumb in the positive direction of the z-axis, as below:

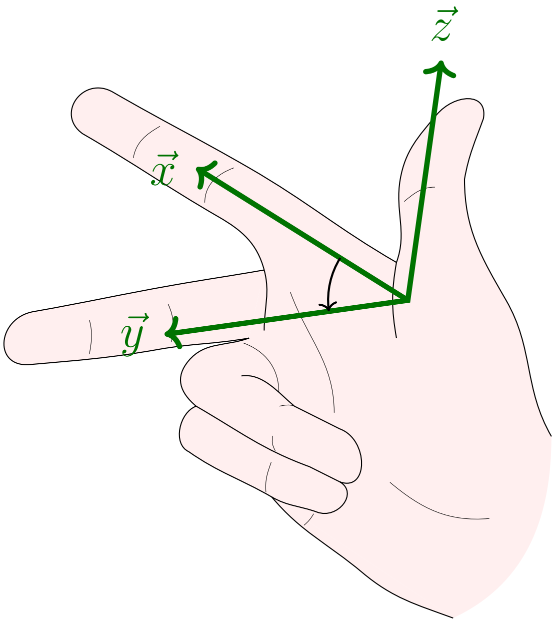

Figure 7.11: **Right-handed coordinate system (author: Izaak Neutelings)**

What we are going to represent now further below (special example), purists mathematicians would denote it as follows (it's nice to have seen at least once this notation as you could meet it in other books):

$$\begin{gathered}f:\mathbb{R}\times\mathbb{R}\mapsto\mathbb{R}\\ z=f(x,y)=\frac{12x}{1+x^2+y^2}\\ (x,y)\in[-10,+10]\times[-5,+5]\end{gathered}\tag{7.1.20}$$

and let us see what it gives with Maple™ 4.00b:

```
>restart:
>with(plots):
>f:=(x,y)->12*x/(1+x^ 2+y^ 2);
>xrange:=-10..10;yrange:=-5..5;
>plot3d(f,xrange,yrange);
```

This will give:

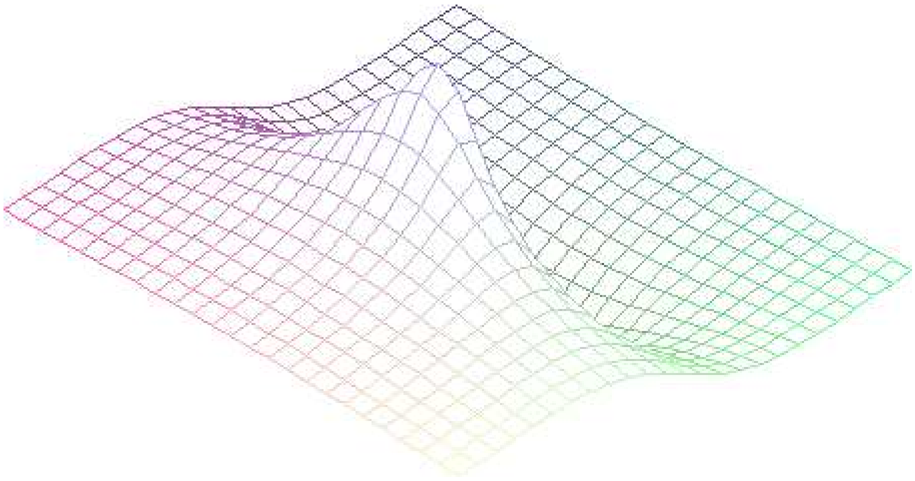

Figure 7.12: **Grid representation of a 3D function in Maple™ 4.00b**

Let us improve the visual by adding a shading interpolation color with warm color to high positions and cold colors to low positions:

```
>plot3d(f,xrange,yrange, style=patchnogrid, grid=[80,50], shading=ZHUE,
axes=FRAME, tickmarks=[3,3,3], labels=[‘x‘,‘y‘,‘f(x,y)‘],
labelfont=[TIMES,BOLD,12], title=‘Graphique rempli‘,
titlefont=[TIMES,BOLD,12], scaling=unconstrained, orientation=[-107,68]);
```

This will give:

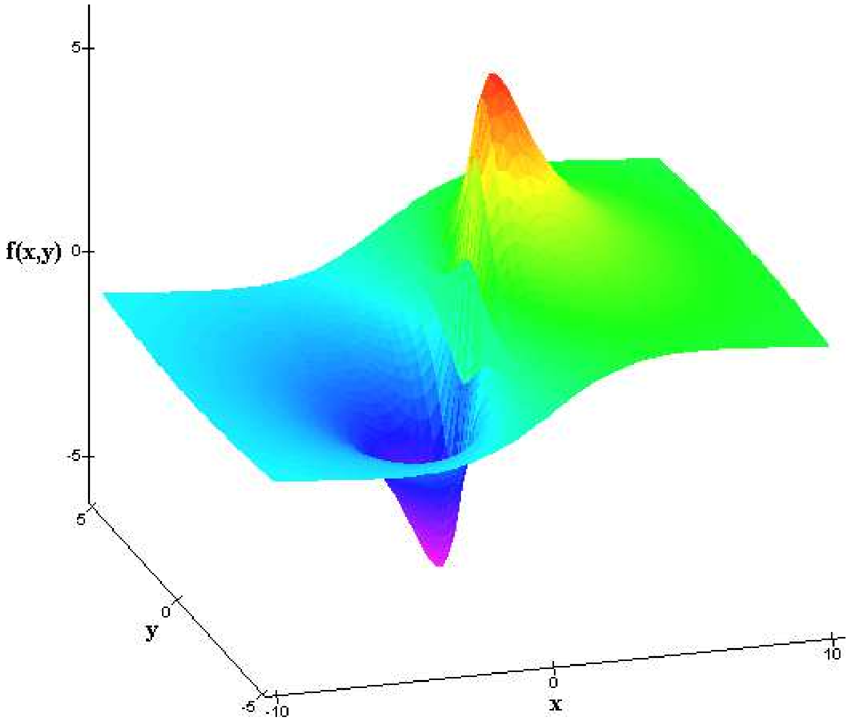

Figure 7.13: **Shading interpolation representation of a 3D function in Maple™ 4.00b**

Let us plot now the "contour lines", also named "isoline" (or "isoquant in Econometry), that represents lines of the same height on the function surface[2] (see section of Differential Geometry page 2857 for a rigorous definition):

```
>plot3d(f,xrange,yrange,style=patchcontour);
```

This will give:

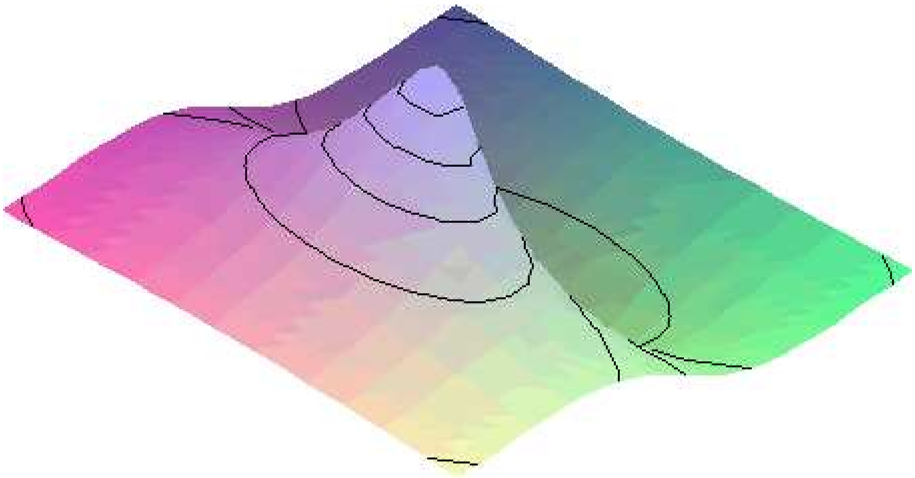

Figure 7.14: **Isolines representation of a 3D function in Maple™ 4.00b**

---

[2] It is a cross-section of the three-dimensional graph of the function $f(x, y)$ parallel to the x, y plane. In cartography, a contour line (often just named a "contour") joins points of equal elevation (height) above a given level, such as mean sea level. A contour map is a map illustrated with contour lines, for example a topographic map, which thus shows valleys and hills, and the steepness of slopes. The contour interval of a contour map is the difference in elevation between successive contour lines.

It's not very nice so let us improve this a little bit:

```
>plot3d(f,xrange,yrange,style=patchcontour,contours=[seq(-7+k/4,k=0..60)],
grid=[80,50],shading=ZHUE,axes=FRAME, tickmarks=[3,3,3],
scaling=unconstrained,orientation=[-107,68]);
```

This will give:

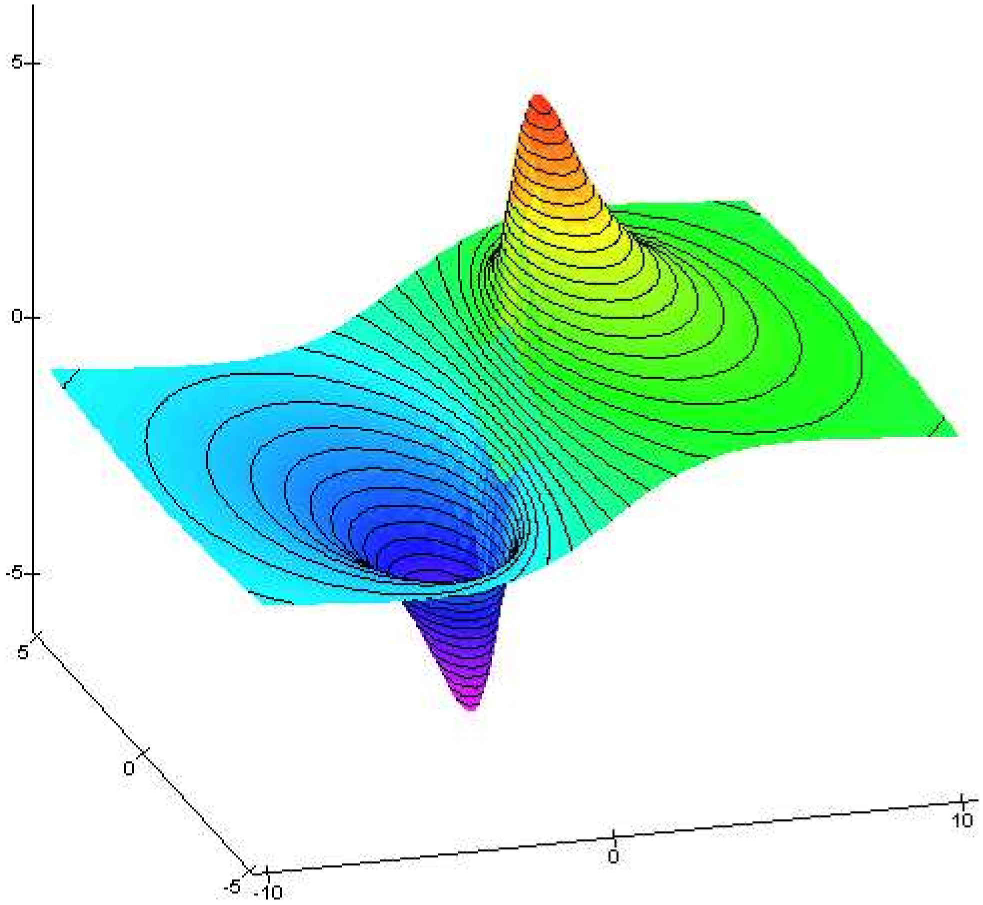

Figure 7.15: **Better representation of a 3D function in Maple™ 4.00b**

With a small rotation to view from above:

```
>plot3d(f,xrange,yrange, style=patchcontour, contours=[seq(-7+k/4,k=0..60)],
grid=[80,50], shading=ZHUE, axes=FRAME, tickmarks=[3,3,3],
scaling=unconstrained, orientation=[-90,0]);
```

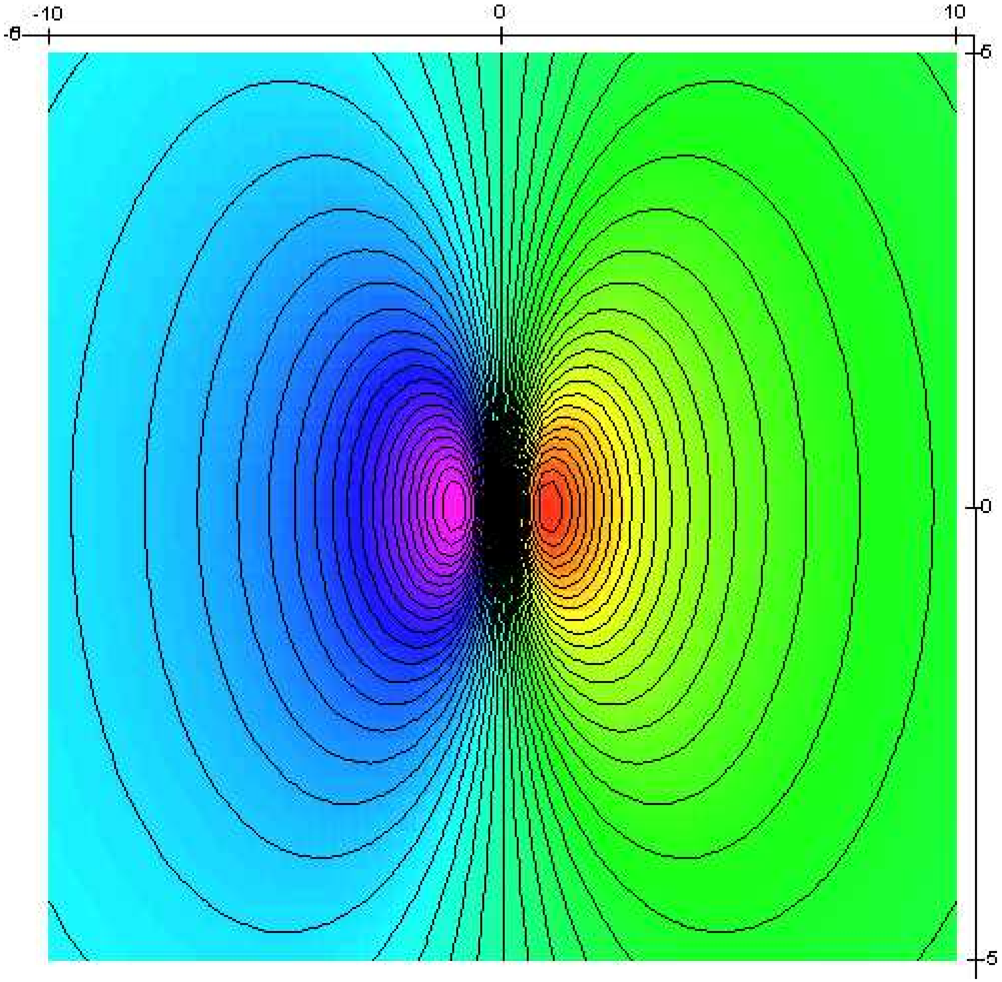

Figure 7.16: **Above representation of a 3D function in Maple™ 4.00b**

And in section view (side view):

```
>plot(f(x,2),x=xrange);
```

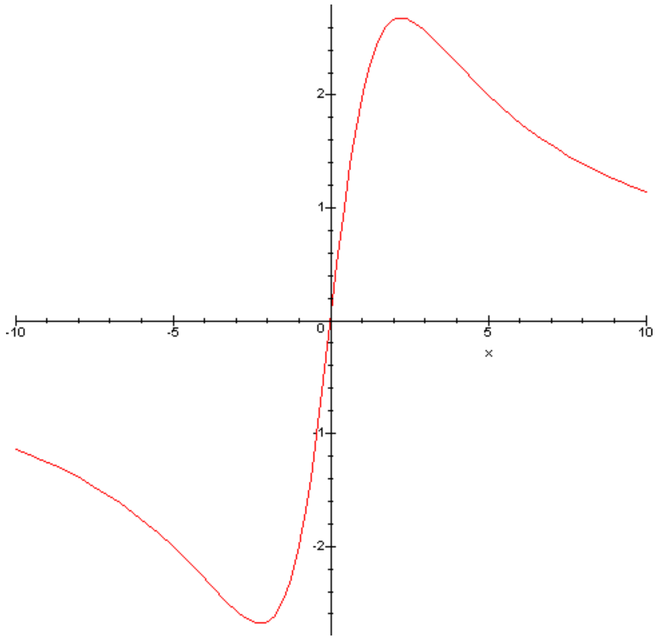

Figure 7.17: **Representation of a section of the pseudo-3D surface**

Or with multiple sections views:

```
>display([seq(plot(f(x,y),x=xrange),y=yrange)]);
```

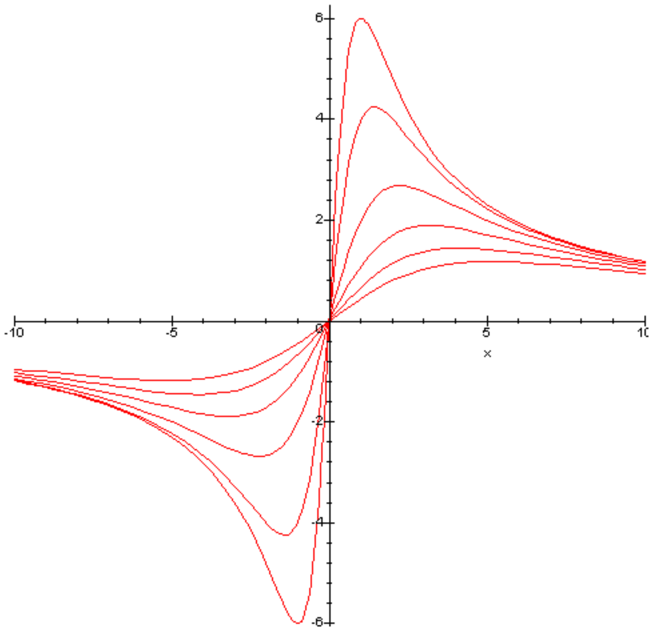

Figure 7.18: **Representation of multiple sections of the pseudo-3D surface**

The reader can also animate the graph above with the following command:

```
>display([seq(display([plot(f(x,k/5),x=xrange),
textplot([6,5,cat('y=',convert(evalf(k/5,2),string))],font=[TIMES,BOLD,16])])
,k=-25..25)],insequence=true, title='Animation',titlefont=[TIMES,BOLD,18]);
```

That's all for this typical and simple example of standard manipulations of an engineer hired in a company and using graphics (in practice it will instead use MATLAB® instead of Maple™ but the reader can refer to the free companion book on MATLAB® that has a few hundreds of pages about graphics).

7.1.1.2.3 2D Vector representations

It is also frequently made use of graphic representations in the context of analytical geometry to simplify analysis or to prove theorems with the help of visual representations (do not abuse of this method!).

Thus, we can easily introduce the concept of "norm" (see section Vector Calculus page 1818) in a very easy way by plotting the distance between two points (in 2D or in 3D) and applying the Pythagorean theorem that will be assumed to be known (see section Euclidean Geometry page 2609).

The main idea of a planar vector representation in physics and engineering labs is that a point P_1 of coordinates (x_1, y_1) that has some physical properties (typically a velocity) will be after a given time at the point P_2 of coordinates (x_2, y_2) supposed to be always in the same plane. In this way, the straight line between P_1 and P_2 is a visualization of the "intensity" of the velocity (and implicitly of the force). When doing that for many points we get a planar representation of a planar vector field (for more example see the companion book on MATLAB®):

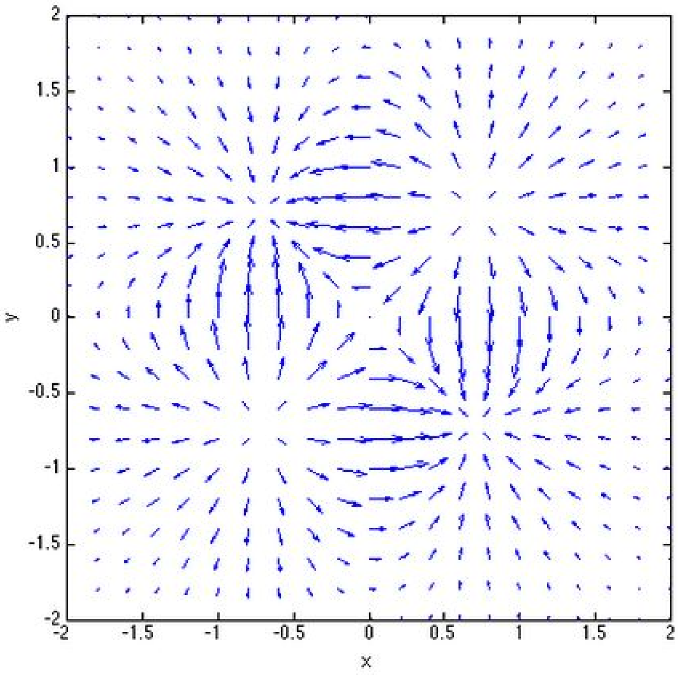

Figure 7.19: **Typical planar vector field with MATLAB®**

Now let us represent three points P_1, P_2, P_3 on a planar graph in which has been defined a referential as presented below:

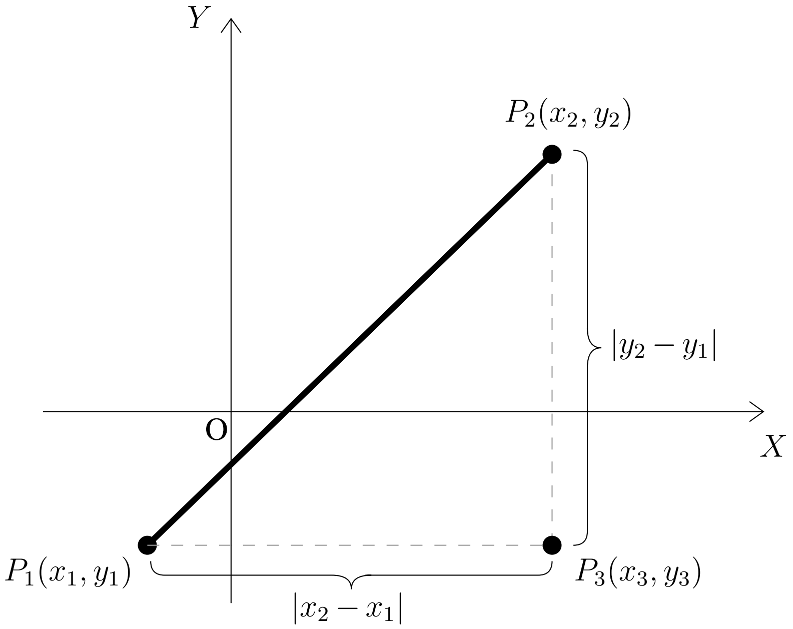

Figure 7.20: **Scenario of thee points in a plane**

We can consider the straight line $\overline{P_1P_2}$ as a vector but not translated at the origin O of the referential.

If $x_1 \neq x_2$ and $y_1 \neq y_2$ (as in the figure above), the points P_1, P_2, P_3 are the vertices of a perpendicular triangle. By applying the Pythagorean theorem (see section Euclidean Geometry page 2609) we can easily calculate the metric distance d between the points P_1 and P_2 as being equal to:

$$[d(P_1,P_2)]^2=[d(P_1,P_3)]^2+[d(P_3,P_2)]^2 \tag{7.1.21}$$

On the figure, we see that:

$$d(P_1,P_3)=|x_2-x_1| \quad \text{and} \quad d(P_3,P_2)=|y_2-y_1| \tag{7.1.22}$$

Since $\forall x\in\mathbb{R}\ |x|^2=x^2$, we can write:

$$d(P_1,P_2)=\sqrt{[d(P_1,P_3)]^2+[d(P_3,P_2)]^2}=\sqrt{(x_2-x_1)^2+(y_2-y_1)^2} \tag{7.1.23}$$

If $x_1=y_1=0$, we end up with a relation named "norm", "module" or "distance" that we have already defined as part of our study of Vector Calculus when the origin of the vector is translated on the origin of the referential (see section of the corresponding name page 1818):

$$d(P_1,P_2)=\sqrt{x_2^2+y_2^2}=\|\vec{v}\| \tag{7.1.24}$$

Theorem 7.1. Obviously, if we consider two points $P_1(x_1,y_1)$, $P_2(x_2,y_2)$, we can determine if a third point $P_3(x_3,y_3)$ is on the mediator (see section Euclidean Geometry page 2597) of the first two and for this that it is obviously sufficient that (by definition of the mediator!):

$$d(P_1,P_3)=d(P_2,P_3) \tag{7.1.25}$$

Remark

We hesitated to put this proof in the section of Analytical Geometry but at then end we have decided that it was a nice example of showing how visual representation can help readers to better understand some subjects.

Proof 7.1.1. As $(x_1,y_1),(x_2,y_2)$ are known, we can easily express an "analytic expression" property of the mediator that is that for each point on the mediator we have:

$$\begin{aligned}
&\sqrt{(x_1-x_3)^2+(y_1-y_3)^2}=\sqrt{(x_2-x_3)^2+(y_2-y_3)^2}\\
&(x_1-x_3)^2+(y_1-y_3)^2=(x_2-x_3)^2+(y_2-y_3)^2\\
&x_1^2-2x_1x_3+\cancel{x_3^2}+y_1^2-2y_1y_3+\cancel{y_3^2}=x_2^2-2x_2x_3^2+\cancel{x_3^2}+y_2^2-2y_2y_3+\cancel{y_3^2}\\
&2y_2y_3-2y_1y_3=x_2^2-2x_2x_3+y_2^2-y_1^2+2x_1x_3-x_1^2\\
&y_32(y_2-y_1)=2(x_1-x_2)x_3+(x_2^2-x_1^2+y_2^2-y_1^2)\\
&y_3=\frac{x_1-x_2}{y_2-y_1}x_3+\frac{x_2^2-x_1^2+y_2^2-y_1^2}{2(y_2-y_1)}=ax_3+b=f(x_3)
\end{aligned} \tag{7.1.26}$$

where a,b are therefore constants and wherein any point that satisfies this relation, which is in this case the equation of a straight line, lies on the mediator.

■ Q.E.D.

Furthermore, it is easy to see that the midpoint of the line segment that coincide with the mediator is given by:

$$M=\left(\frac{x_1+x_2}{2},\frac{y_1+y_2}{2}\right) \tag{7.1.27}$$

So we see that with a simple visual representation, we can achieve results that are sometimes (...) more obvious for students.

Let us use this example to define some concepts on that we will come back further and do some reminders.

Definition (#7.1.268): Any function of the form of a polynomial (see section Calculus page 1368) of degree 1 with constant real coefficients:

$$y=f(x)=ax+b \tag{7.1.28}$$

is the analytic expression of what we name a "straight line" or "linear equation" of "slope" a and "intercept" b (when $x=0$).

Obviously, if:

$$y=f(x)=b \tag{7.1.29}$$

the line is horizontal if we graphically represent it since y is constant for all x and is equal to b. Conversely, if:

$$x=f(y)=a \tag{7.1.30}$$

the straight line will be vertical in the $x\text{O}y$ referential.

7.1.1.2.4 Properties of visual representations

Depending on the type of graph we visualize (especially graphics planes) it is possible to extract some basic properties. Let us see the most important one to know for univariate functions:

$$y = f(x) \tag{7.1.31}$$

P1. The graph of a function is "symmetrical about the y-axis" if the change in from x to $-x$ in the function does not change the value of y such that:

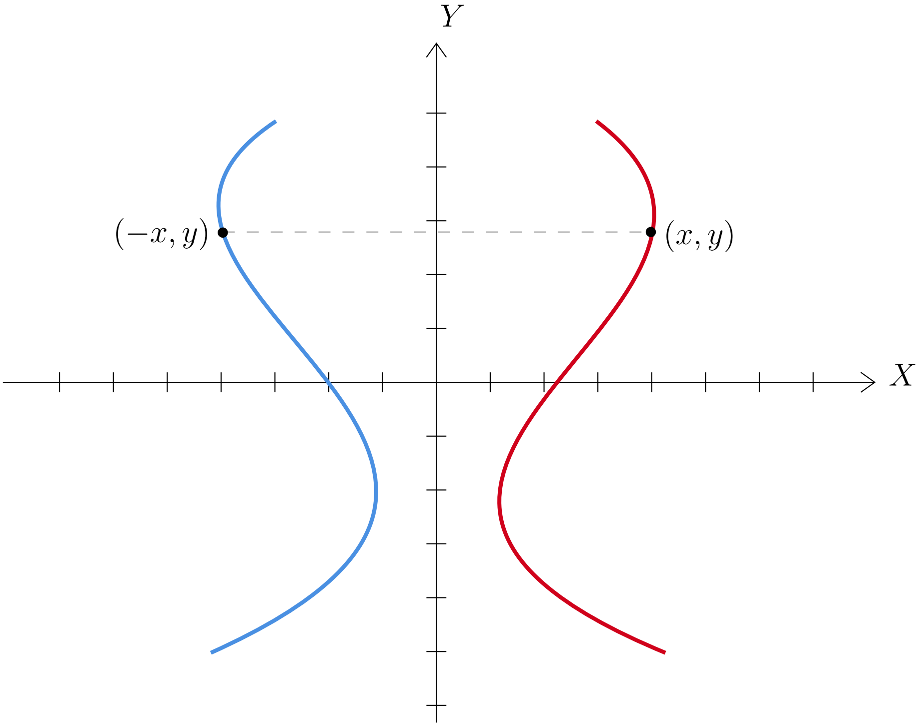

Figure 7.21: **Example of symmetry through the y-axis of a function**

P2. The graph of a function is "symmetrical about the x-axis" if the change from y to $-y$ does not change the value of x such that:

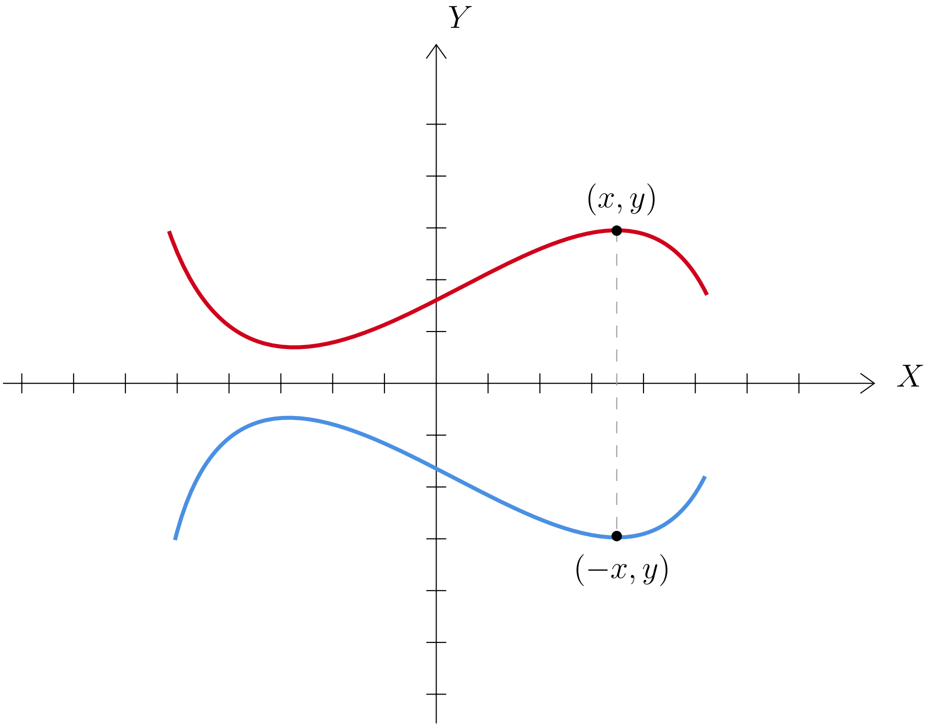

Figure 7.22: **Example of symmetry through the x-axis of a function**

P3. The graph of a function is "symmetrical about the origin O" if the simultaneous change of y to $-y$ and from x to $-x$ gives the following result (that is to say that the change in the sign of one variable change the sign of the other):

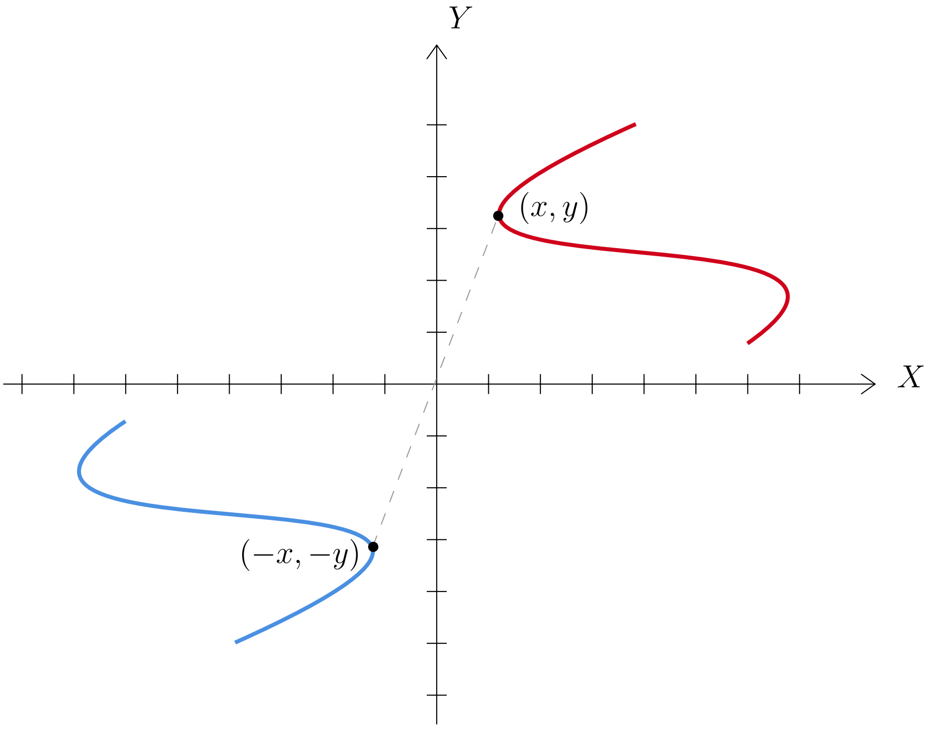

Figure 7.23: **Example of symmetry through the origin O of a function**

P4. Given a function $y=f(x)$, if we add a constant $c^{te}\geq 0$ to this function as:

$$y=f(x)+c^{te} \tag{7.1.32}$$

then the function $f(x)$ is shifted (or "translated") vertically upwards of a distance c^{te} as presented in the figure below:

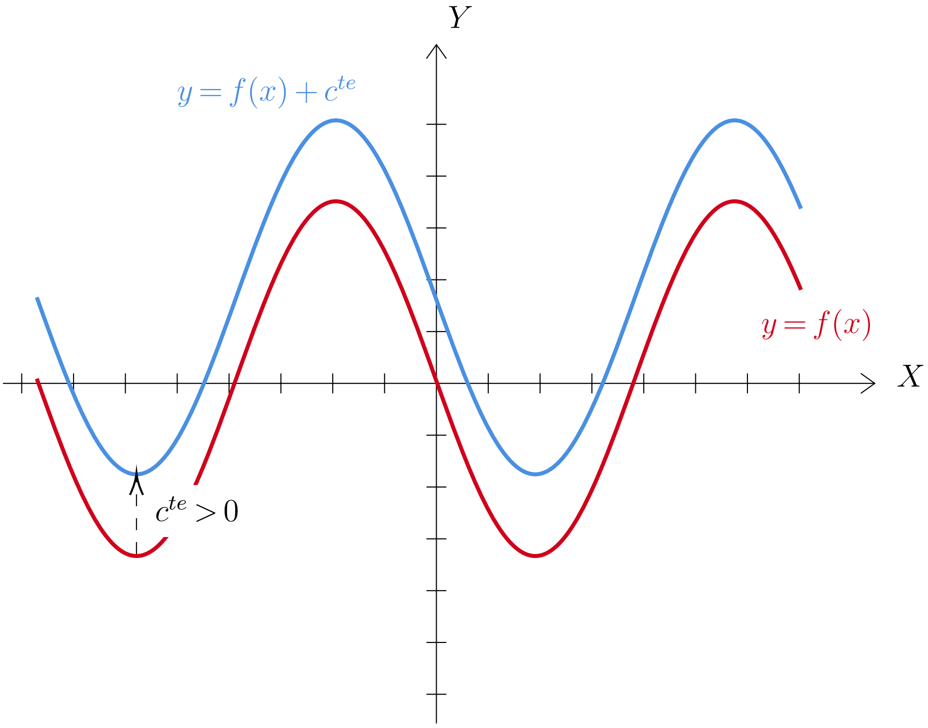

Figure 7.24: Example of a positive vertical translation of a function

And conversely if $c^{te}\geq 0$ but:

$$y=f(x)-c^{te} \tag{7.1.33}$$

then the function $f(x)$ is obviously translated vertically downwards:

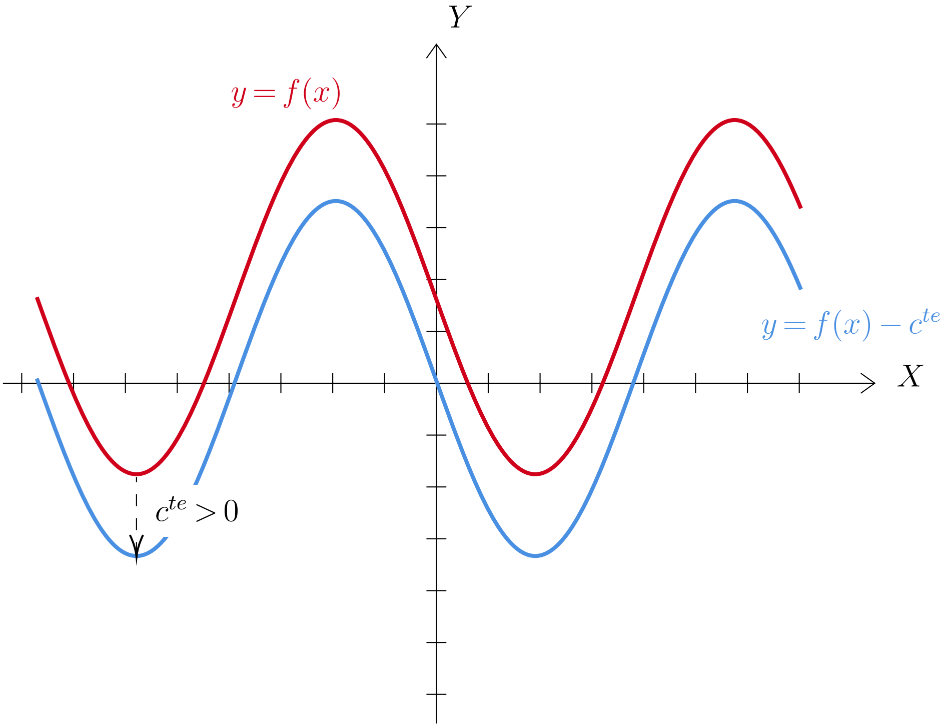

Figure 7.25: Example of a negative vertical translation of a function

We can also consider horizontal translations of functions. Specifically, if we have still $c^{te} > 0$, then $y = f(x)$ is translated horizontally to the right if we write:

$$y = f(x - c^{te}) \tag{7.1.34}$$

which graphically is represented by:

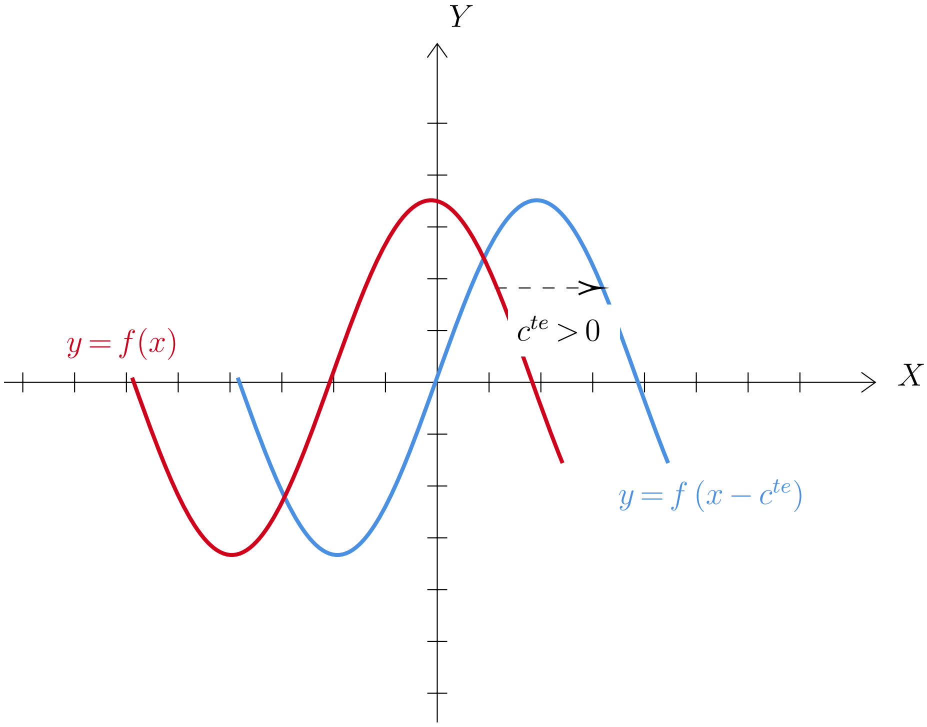

Figure 7.26: Example of negative horizontal translation of a function

and conversely, translated horizontally to the left, if we write:

$$y = f(x + c^{te}) \tag{7.1.35}$$

as shown in the graph below:

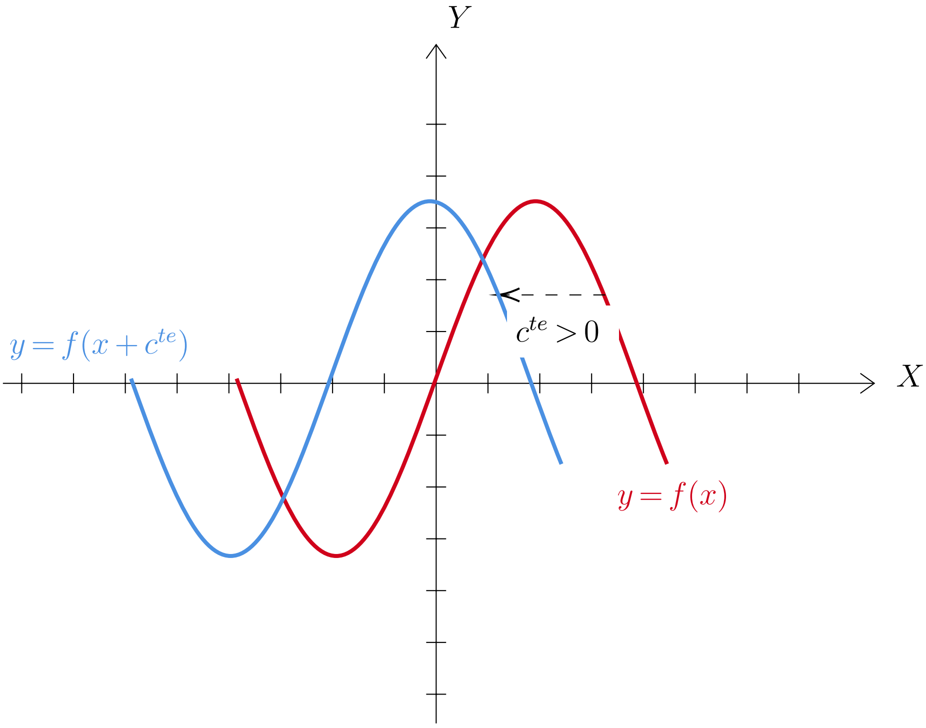

Figure 7.27: **Example of positive horizontal translation of a function**

To stretch or compress vertically a function, we simply multiply $y=f(x)$ by a constant $c^{te}>1$ and respectively $0\leq c^{te}<1$ as:

$$y=c^{te}f(x) \tag{7.1.36}$$

and don't forget that if a function is linear then we have the special property $f(\lambda x)=\lambda f(x)$.

This is graphically represented for the case $c^{te}>1$ by:

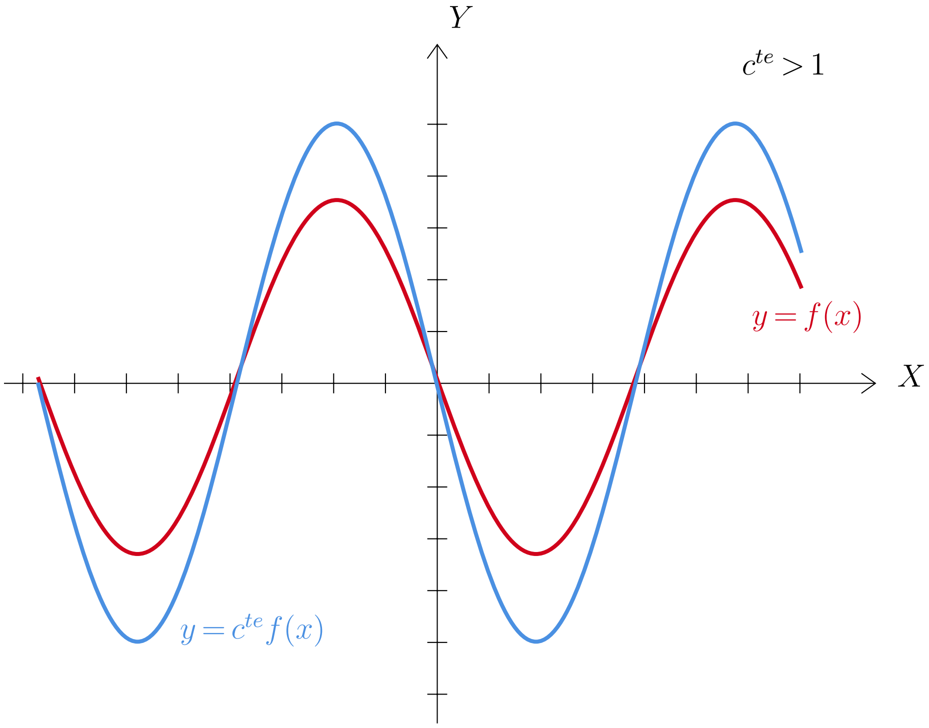

Figure 7.28: **Example of vertical stretch of a function**

and when $0 \leq c^{te} < 1$ by:

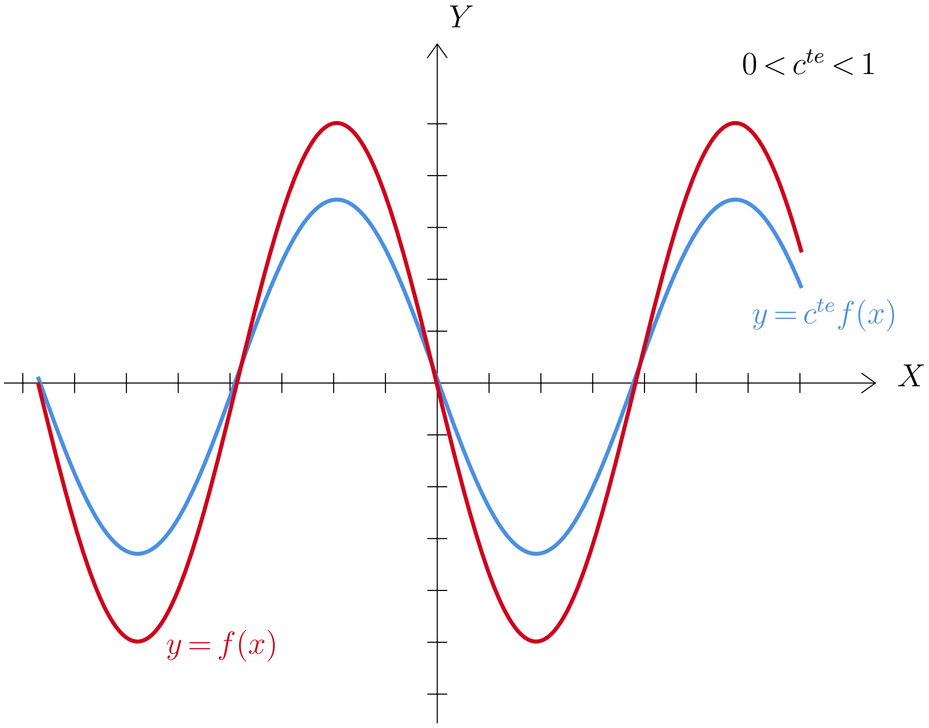

Figure 7.29: **Example of vertical compression of a function**

To stretch or compress a function horizontally, by the same way, we just need to multiply the variable x by a constant $c^{te} > 1$ and respectively $0 < c^{te} < 1$ as:

$$y = f(c^{te} x) \tag{7.1.37}$$

This is graphically represented for the case $0 < c^{te} < 1$ by:

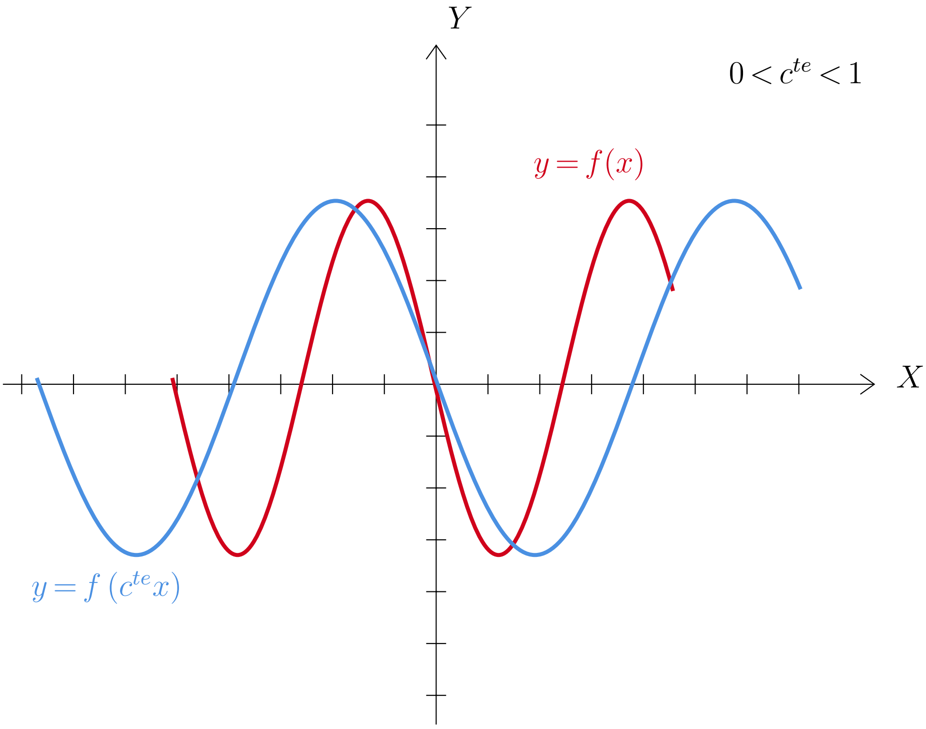

Figure 7.30: **Example of horizontal stretch of a function**

and when $c^{te} > 1$ by:

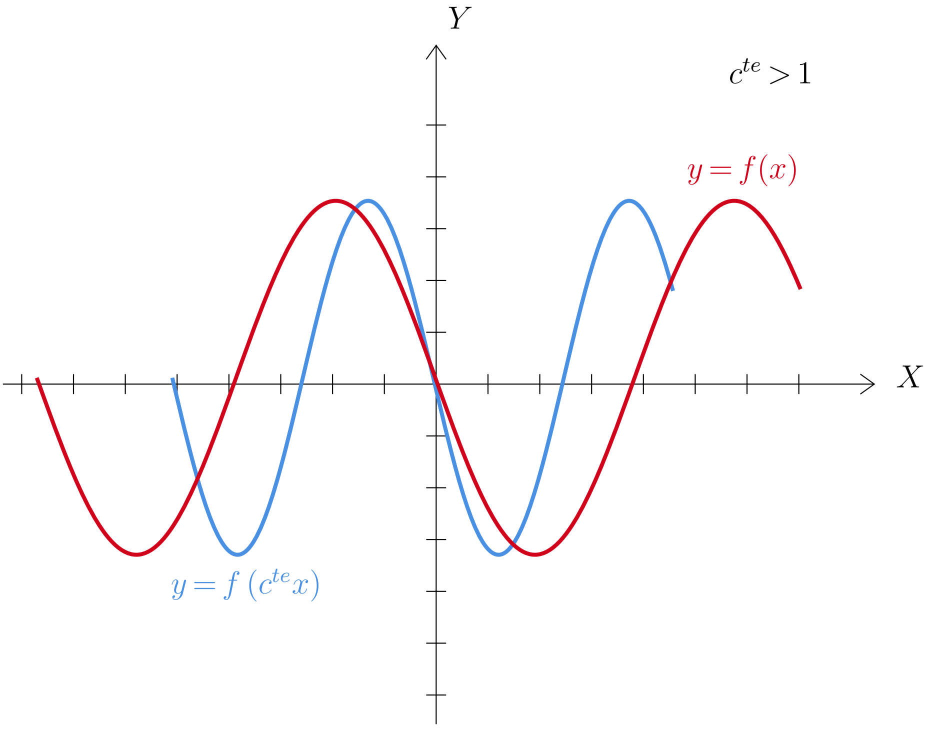

Figure 7.31: **Example of horizontal downscale of a function**

Remark

Translate, stretch, compress a function or apply it a symmetry is transforming it. The plot resulting from these transformations is named the "transformed" from the initial plot.

Definitions (#7.1.269): We say that a function f is (we simplify the definition using an univariate function):

D1. A "constant function" on an interval I if for each pair (x_1, x_2) of elements of I such that $x_1 \neq x_2$, we have $f(x_1) = f(x_2)$. What we denote in a condensed manner by:

$$\forall (x, y) \in I^2 : \quad f(x) = f(y) = c^{te} \tag{7.1.38}$$

D2. An "increasing function" or an "increasing function in the broadest sense" on the interval I if for each pair (x_1, x_2) of elements of I such that $x_1 \leq x_2$, we have $f(x_1) \leq f(x_2)$. What we denote in a condensed manner by:

$$\forall (x, y) \in I^2 \wedge (x \leq y) : \quad f(x) \leq f(y) \tag{7.1.39}$$

D3. A "decreasing function" or an "decreasing function in the broadest sense" on the interval I if for each pair (x_1, x_2) of elements of I such that $x_1 \leq x_2$, we have $f(x_1) \geq f(x_2)$. What we denote in a condensed manner by:

$$\forall (x, y) \in I^2 \wedge (x \leq y) : \quad f(x) \geq f(y) \tag{7.1.40}$$

Remark

A function is a "monotonic function" or "monotonic function in the broadest sense" on an interval I if it is increasing or decreasing in this interval.

D4. A "strictly increasing function" on the interval I if for each pair (x_1, x_2) of elements of I such that $x_1 \leq x_2$, we have $f(x_1) < f(x_2)$. What we denote in a condensed manner by:

$$\forall (x, y) \in I^2 \wedge (x < y) : \quad f(x) < f(y) \tag{7.1.41}$$

D5. A "strictly decreasing function" on the interval I if for each pair (x_1, x_2) of elements of I such that $x_1 \leq x_2$, we have $f(x_1) > f(x_2)$. What we denote in a condensed manner by:

$$\forall (x, y) \in I^2 \wedge (x < y) : \quad f(x) > f(y) \tag{7.1.42}$$

Remark

A function is a "strictly monotonic function" on an interval I if it is strictly increasing or decreasing in this interval.

Here is a visual summary of some of the monotonicity types defined above:

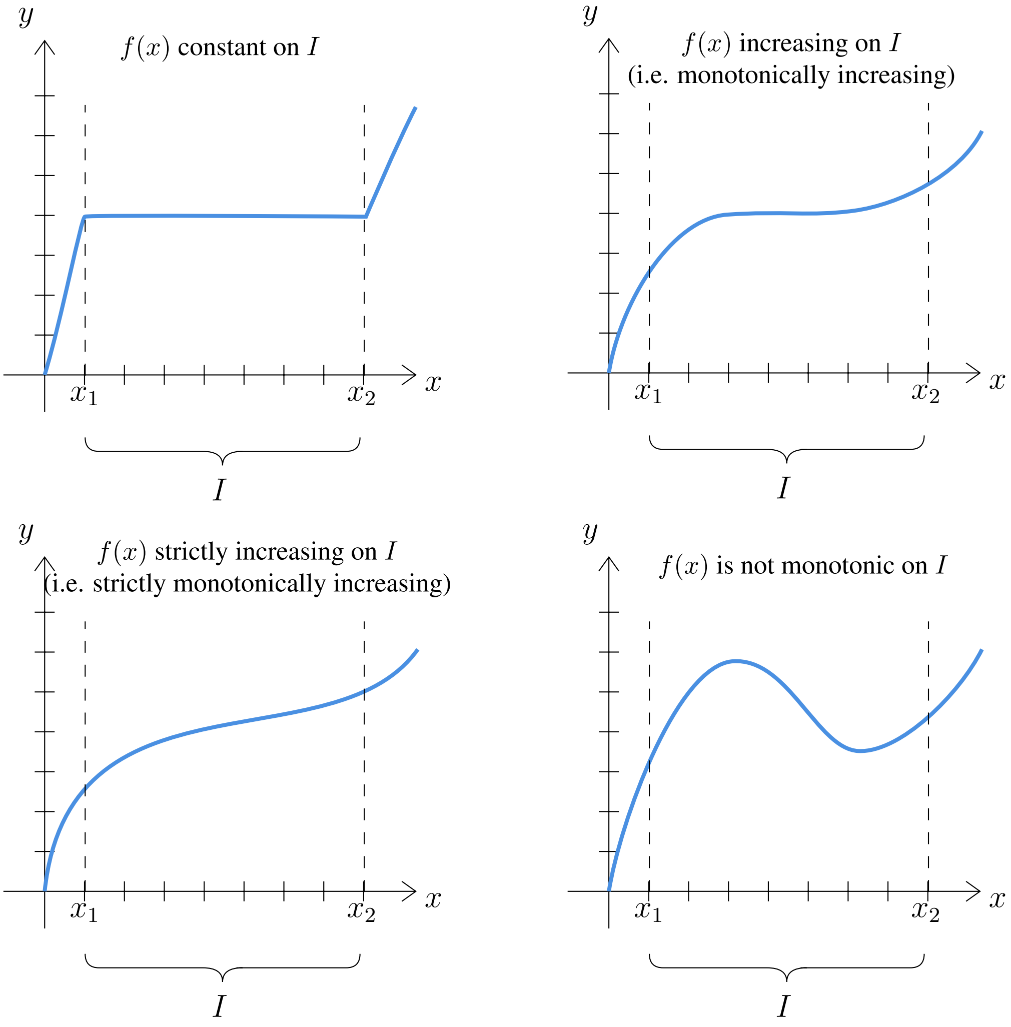

Figure 7.32: **Summary of some of the types of monocities of univariate functions**

There are plenty of other existing visuals/charts representations. You can find in the thumbnail gallery below 206 of them (excepted for two of them, they were all made with the `R` software and the code to create most of them is available in the corresponding companion book):

7.1.1.3 Analytical Representations

The analytical method of representation is by far the most used and consists of representing any function in an "analytic expression" or "closed form" which is a symbolic and abstract mathematical notation of all known mathematical operations that must be applied in a certain order to numbers and letters expressing constants or variables that we seek to analyse.

Note that by "all known mathematical operations", we consider not only the mathematical operations seen in the chapter of Arithmetics (addition, subtraction, root extraction, etc.) but also all the operations that will be defined later in this textbook.

If the functional dependence $y=f(x)$ is such that f is an analytic expression, then we say that the "function y of x" is "given analytically ".

Here are some examples of simple analytical expressions:

$$y=x^4-2, y=\frac{x+1}{x-1}, y=\sqrt{1-x^2} \tag{7.1.43}$$

When we have determined the equation of the mediator (see page 2195), we have obtained an analytical expression of the visual straight line that characterize it as a function of the type:

$$\boxed{f(x)=y=ax+b} \tag{7.1.44}$$

which we recall, is the analytical expression of the equation of a straight line, also named "linear equation" or "affine function", on a plane where two points are known $P_1(x_1,y_1), P_2(x_2,y_2)$, the slope is given by the ratio of vertical growth on the horizontal growth as:

$$a=\frac{y_2-y_1}{x_2-x_1}\equiv\frac{\Delta y}{\Delta x} \tag{7.1.45}$$

A friendly and trivial application is to prove analytically that two non-vertical lines are parallel if and only if they have the same slope. Thus, given two lines with the equations:

$$y_1=ax_1+b_1 \qquad y_2=a_2+b_2 \tag{7.1.46}$$

The lines intersect at a point (x,y) if and only if values of y are equal for a certain x, that is to say:

$$a_1x+b_1=a_2x+b\Leftrightarrow(a_1-a_2)x=b_2-b_1 \tag{7.1.47}$$

The last equation can be solved with respect to x if and only if $a_2-a_2\neq 0$. We have therefore proved that the lines y_1,y_2 intersect if and only if $a_1\neq a_2$. Therefore, they do not intersect (are parallel) if and only if $a_1=a_2$.

In a quite simple way by applying the Pythagorean theorem, it is not difficult (see section Analytical Geometry page 2764) to determine that the equation of a circle with center $C(h,k)$

has for equation (it is of use in mathematics not explain y for the equation of the circle therefore the equation of the latter is much more visually aesthetic and speaking):

$$r=\sqrt{(x-h)^2+(y-k)^2} \tag{7.1.48}$$

In these examples the functions are expressed analytically by a single formula (equality between two analytical expressions) which defines at the same time the "natural domain of definition" of the functions.

Definition (#7.1.270): The "natural domain of definition" of a function given by an analytical expression is the set of x values for which the expression on the right-hand side has a definite value.

For example the function:

$$y=\frac{x+1}{x-1} \tag{7.1.49}$$

is defined for all values of x except the value $x=1$ where we have a singularity (division by zero).

Remark

There are an infinite number of functions and we can not expose them all here, however we will meet more than a thousand on this entire book and should amply suffice to get an idea of their study.

And we have the famous following "table of variations" that is also considered as an analytical tool and also used by some teachers to study the basics of the derivative f' of a function f (see section Differential and Integral Calculus page 1450). For example with the function x^3-3x^2+2 (already seen in the previous mentioned section):

x	$-\infty$		0		2		$+\infty$
f'		$+$	0	$-$	0	$+$	
f		↗		↘		↗	

Whose corresponding plot is:

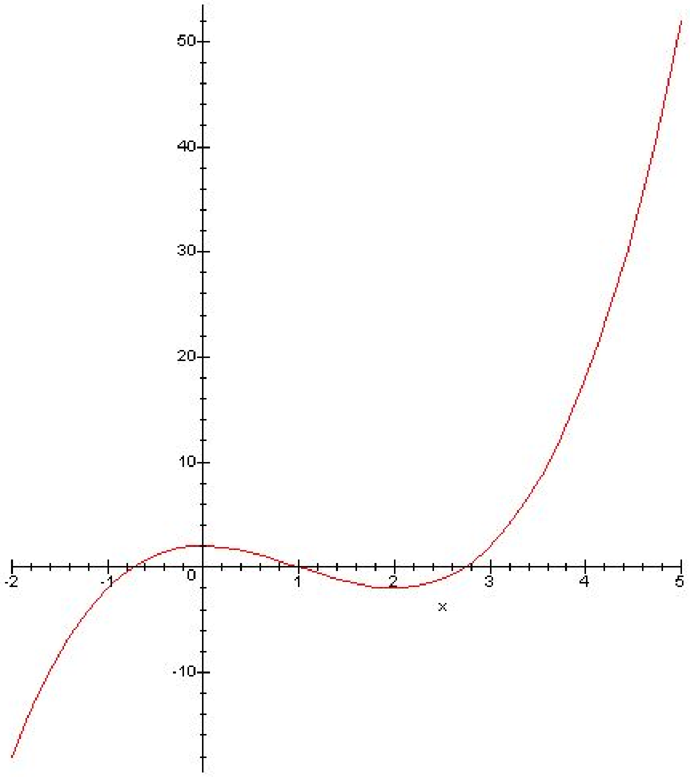

Figure 7.34: **Plot of function** $x^3 - 3x^2 + 2$

7.1.2 Functions

In mathematics, a function is a relation between a set of inputs and a set of permissible outputs with the property that each input is related to exactly one output.

Functions of various kinds are the central objects of investigation in most fields of modern mathematics. There are many ways to describe or represent a function. Some functions may be defined by a formula or algorithm that tells how to compute the output for a given input. Others are given by a picture, named the "graph" of the function. In science, functions are sometimes defined by a table that gives the outputs for selected inputs. A function could be described implicitly, for example as the inverse to another function or as a solution of a differential equation.

First remember the definitions already given earlier during our study of graphical representation of functions:

Definitions (#7.1.271): We say that a function f is (we simplify the definition using an univariate function):

D1. A function is a "constant function" on an interval I if for each pair (x_1,x_2) of elements of I such that $x_1\neq x_2$, we have $f(x_1)=f(x_2)$. What we denote in a condensed manner by:

$$\forall (x,y)\in I^2: \quad f(x)=f(y)=c^{te} \tag{7.1.50}$$

D2. A function is an "increasing function" or an "increasing function in the broadest sense" on the interval I if for each pair (x_1,x_2) of elements of I such that $x_1\leq x_2$, we have $f(x_1)\leq f(x_2)$. What we denote in a condensed manner by:

$$\forall (x,y)\in I^2\wedge(x\leq y): \quad f(x)\leq f(y) \tag{7.1.51}$$

D3. A function is an "decreasing function" or an "decreasing function in the broadest sense" on the interval I if for each pair (x_1,x_2) of elements of I such that $x_1\leq x_2$, we have $f(x_1)\geq f(x_2)$. What we denote in a condensed manner by:

$$\forall (x,y)\in I^2\wedge(x\leq y): \quad f(x)\geq f(y) \tag{7.1.52}$$

Remark

A function is a "monotonic function" or "monotonic function in the broadest sense" on an interval I if it is increasing or decreasing in this interval.

D4. A function is a "strictly increasing function" on the interval I if for each pair (x_1,x_2) of elements of I such that $x_1\leq x_2$, we have $f(x_1)<f(x_2)$. What we denote in a condensed manner by:

$$\forall (x,y)\in I^2\wedge(x<y): \quad f(x)<f(y) \tag{7.1.53}$$

D5. A function is an "strictly decreasing function" on the interval I if for each pair (x_1,x_2) of elements of I such that $x_1\leq x_2$, we have $f(x_1)>f(x_2)$. What we denote in a condensed manner by:

$$\forall (x,y)\in I^2\wedge(x<y): \quad f(x)>f(y) \tag{7.1.54}$$

Remark

A function is a "strictly monotonic function" on an interval I if it is strictly increasing or decreasing in this interval.

And let us add now complementary definitions:

Definitions (#7.1.272):

D1. We say that y is a function of x and we will write $y=f(x), y=\varphi(x)$, etc., if for every value of the variable x belonging to a certain domain of definition (set) D, corresponds a value of the variable y in another target domain of definition (set) E. What we denote in various ways (the third one being the most recommended):

$$D \xrightarrow{f} E \qquad f:D\rightarrow E \qquad f:D\mapsto E \tag{7.1.55}$$

The variable x is named "independent variable" or "input variable" or even "exogenous variable" and y the "dependent variable" or "endogenous variable".

The dependence between the variables x and y is named a "functional dependency". The letter f, which in the symbolic notation of functional dependence, indicates that we need to apply some operations to x to obtain the corresponding y value.

Sometimes we write:

$$y=y(x) \tag{7.1.56}$$

rather than:

$$y=f(x) \tag{7.1.57}$$

In the latter case the letter y expresses at the same time the value of the function and the symbol of operations applied to x.

Remark

As we saw it during our study in the section Set Theory, an application (or function) may be injective, surjective or bijective:

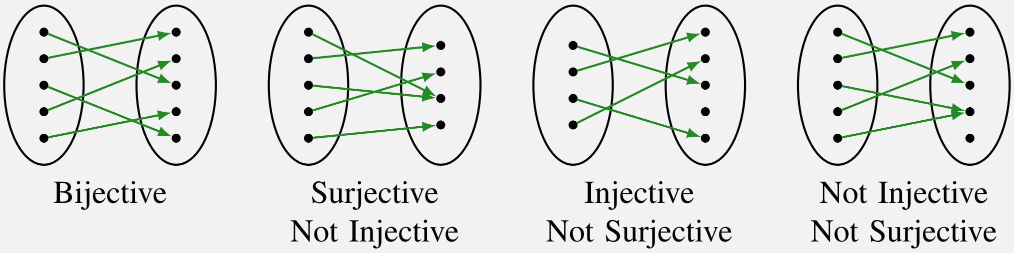

Figure 7.35: **Quick summary of applications/functions types**

It is therefore necessary that the reader for whom these concepts are unknown goes in priority read these definitions.

D2. The set of x values (inputs) for which the value of the function y is given by the function $f(x)$ is named the "range of existence" of the function or "domain of definition" of the function and denoted in this textbook by the letter D.

The set of outputs of $f(x)$ is named the "image" or sometimes the "codomain" and denoted in this textbook by the letter E. When study of the point of view of the knowledge of the output values only, the set of x is named the "pre-image".

D3. A function $f(x)$ is named a "periodic function" if there is a constant c^{te} such that the function's value does not change when we add (or subtract) that constant to the independent variable such as:

$$y=f(x\pm c^{te})=f(x) \tag{7.1.58}$$

which corresponds to a translation along the x-axis. The smallest constant satisfying this condition is named the "period" of the function. It is frequently denoted by the letter T in physics.

The most common periodic functions known by students and engineers are the trigonometric functions (see section of the corresponding name page 2503):

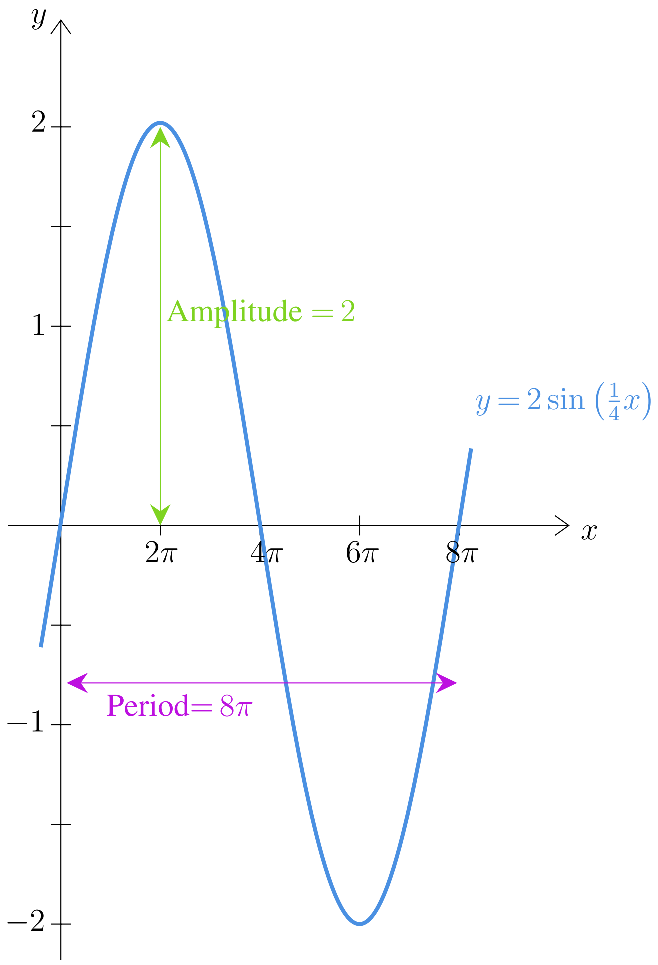

Figure 7.36: **Example of a very simple periodic function with period and amplitude**

Or let us consider a little bit more complicated example:

Remark

The sum of two periodic functions with different periods is not necessarily periodic and there is no general formula to get the period of a function that is the sum of n other functions!

D4. In differential calculus (see section Differential and Integral Calculus page 1450), the expression:

$$\frac{f(x+h)-f(x)}{h} \tag{7.1.59}$$

with $h\neq 0$ is of particular interest. We name it a "growth quotient" (we discuss this in much more detail in our study of differential and integral calculus).

D5. We use certain properties of functions for easy graphical representation and analysis or mathematical simplifications. In particular, a function $f(x)$ is named "even function" if:

$$f(x)=f(-x) \tag{7.1.60}$$

for all x in its definition domain.

That is to say as we already seen previously, it is symmetric relatively with the y-axis:

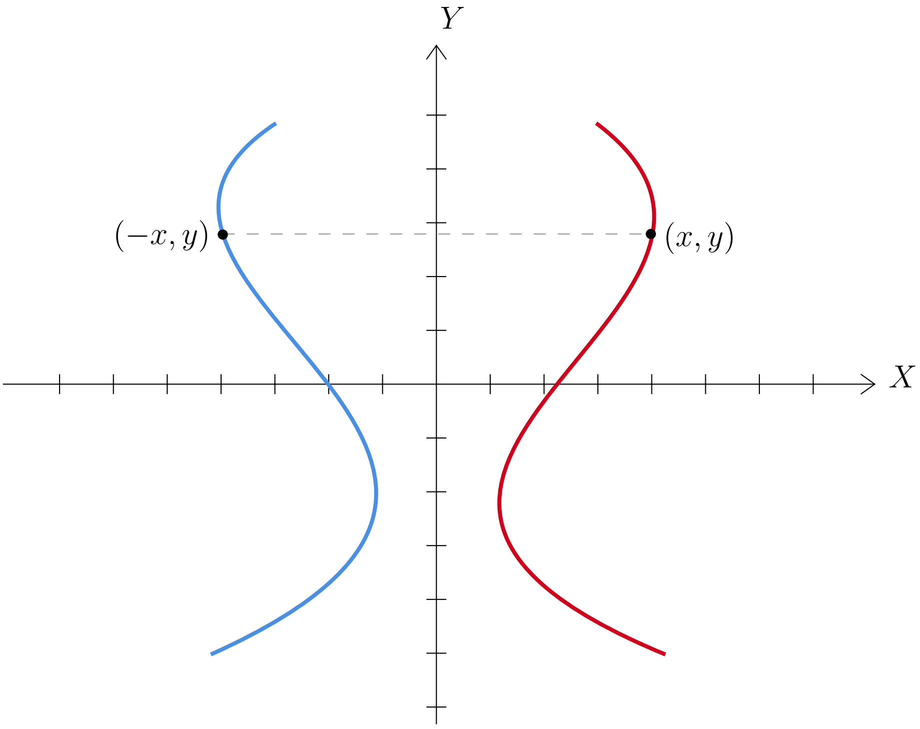

Figure 7.37: **Example of an even function**

A function $f(x)$ is named "odd function" if:

$$f(-x)=-f(-x) \tag{7.1.61}$$

for all x in its definition domain.

That is to say as we already seen previously, it is symmetric relatively with the origin:

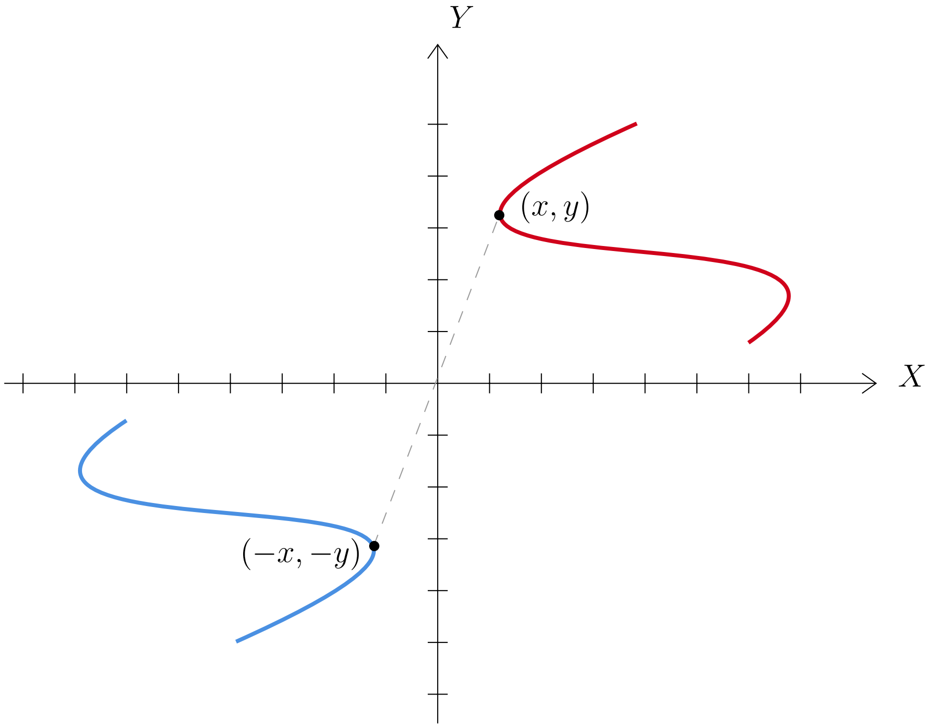

Figure 7.38: **Example of an odd function**

So, to summarize, an even function is a function that is independent of the sign of the variable and an odd function change of sign when we change the sign of the variable (the spiral of Cornus in the section Civil Engineering is a good practical example of odd function). This concept will be very useful to us to simplify some very useful developments in physics (such as Fourier transforms of odd or even functions for example, or the calculation of certain integrals!).

Theorem 7.2. Let us now show that any function $f(x)$ is the sum of an even function $g(x)$ and an odd function $h(x)$.

Remark

Remember that this type of theorem linking a general concept to a particular case and its opposite is often found in mathematics. We will see such examples in tensor calculus with the symmetric and antisymmetric tensor (see section Tensor Calculus page 2085 and page 2088) or in quantum physics with the Hermitian or non-Hermitian operators (see section Wave Quantum Physics page 4695 and page 4716).

Proof 7.2.1. Let us write:

$$f(x)=g(x)+h(x) \tag{7.1.62}$$

Then:

$$f(-x)=g(x)-h(x) \tag{7.1.63}$$

If we sum then we get:

$$g(x)=\frac{f(x)+f(-x)}{2} \tag{7.1.64}$$

and by subtracting:

$$h(x)=\frac{f(x)-f(-x)}{2} \tag{7.1.65}$$

So there is really and odd and even decomposition of any function!!!

■ Q.E.D.

Finally, it is important to note that:

- The product of two even functions is an even function
- The product of two odd functions is an even function
- The product of an even and odd function is an odd function

Let us see a short proof of the last property because we will need it in the chapter on Geometry.

Proof 7.2.2. Let $g(x)$ be an even function and $h(x)$ an odd function such as:

$$g(-x)=g(x) \tag{7.1.66}$$
$$h(-x)=-h(x) \tag{7.1.67}$$

Therefore:

$$q(-x)=g(-x)h(-x)=g(x)(-h(x))=-g(x)h(x)=-q(x) \tag{7.1.68}$$

■ Q.E.D.

D6. In general, if $f(x)$ and $g(x)$ are arbitrary functions, we use the terminology and notations given in the following table:

Terminology	**Value of the function**
Sum $f+g$	$(f+g)(x)=f(x)+g(x)$
Difference $f-g$	$(f-g)(x)=f(x)-g(x)$
Product $f\cdot g$	$(f\cdot g)(x)=f(x)g(x)$
Quotient $\dfrac{f}{g}$	$\left(\dfrac{f}{g}\right)(x)=\dfrac{f(x)}{g(x)}$

Table 7.3: **Terminology about functions**

The definition domains of $f+g$, $f-g$, $f\cdot g$ are the intersection I of the definition domain of $f(x)$ and $g(x)$, that is to say, the numbers which are common to both domains of definition. The domain of definition of f/g is meanwhile the subset I of all x such that $g(x)\neq 0$.

D7. Let y be a function of f of u such that $y=f(u)$ and u a function g of x such that $u=g(x)$, then y depends on x and we have what we name a "composite function" that we denote:

$$\boxed{y=f(g(x))=(f\circ g)(x)} \tag{7.1.69}$$

The last equality should be read "f round g" and not confuse with the "round" symbol with the notation of the dot product that we have seen during our study of the section Vector Calculus page 1821.

The domain of definition of the composite function is either identical to the entire domain of definition of the function $u=g(x)$ or the part of the domain in which the values of u are such that the corresponding values $f(u)$ belong to the domain of definition of this function.

Obviously the principle of composite function can be applied not only once, but an arbitrary number of times such that $y=f(g(h(t)))$ and so on...

In computing science a function may compose with itself a given number of times n, such that $f(f(f(f(f\ldots)))))=f^n$ that must not be confuse with the power notation $f^n(x)$.

If u does not depend on another variable (or it is not itself a composite function), then we say that $f(u)$ is an "elementary function".

Obviously there are an infinite number of elementary functions but most can be classified into families whose expression is similar to one of the following (here they are only univariate functions):

- "Linear functions":

  $$f(x)=ax \tag{7.1.70}$$

  They are simply functions representing straight lines of slope a passing through the origin of the axis.

- "Affine functions":

  $$f(x)=ax+b \tag{7.1.71}$$

  They are simply functions representing straight lines of slope a passing through the origin of the axis or not (linear function with a translation).

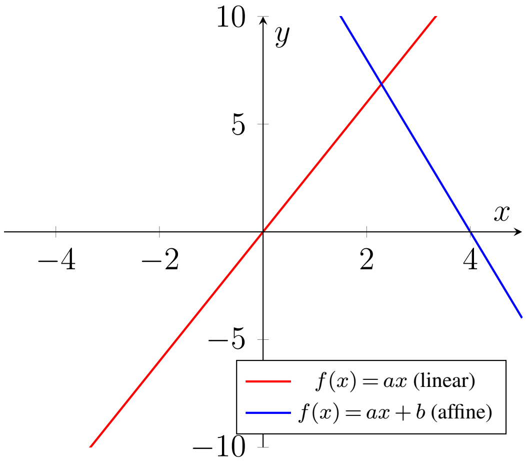

Figure 7.39: **Univariate affine and linear function**

- "Power functions":

  $$f(x)=x^m \tag{7.1.72}$$

where $m \in \mathbb{R}$. Functions involving roots are often named "radical functions".

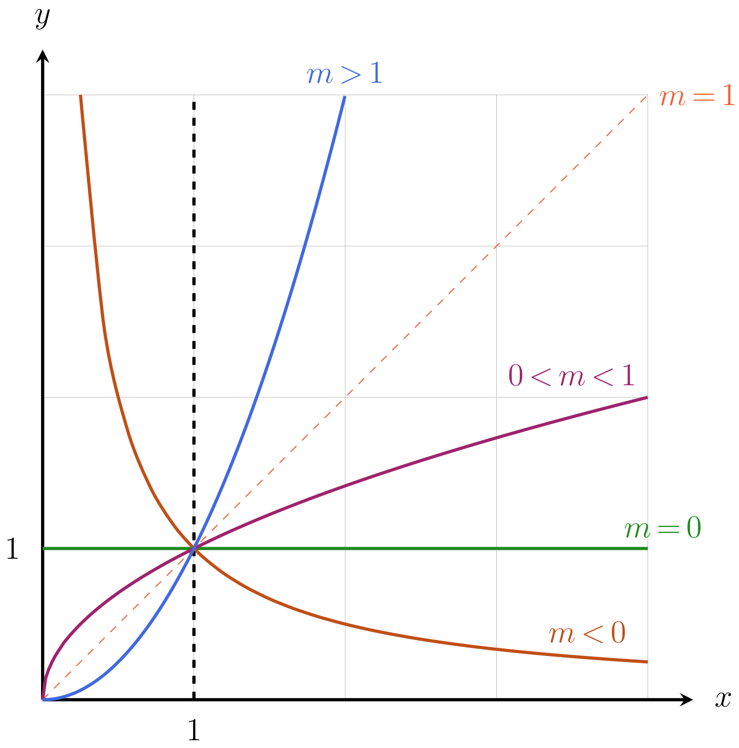

Figure 7.40: **Different plots of simple power functions**

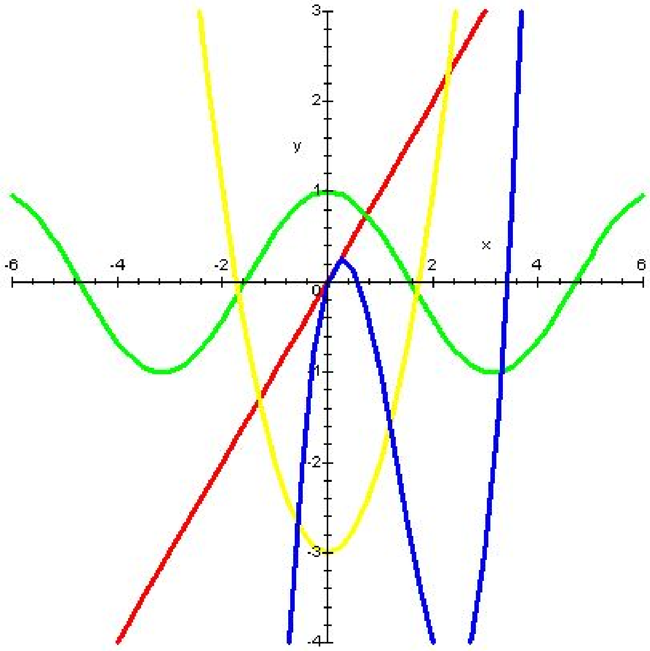
- "Absolute value functions" (see section Arithmetic Operators page 324 for the definition and the study of the "absolute value"):

$$f(x) = |x| \tag{7.1.73}$$

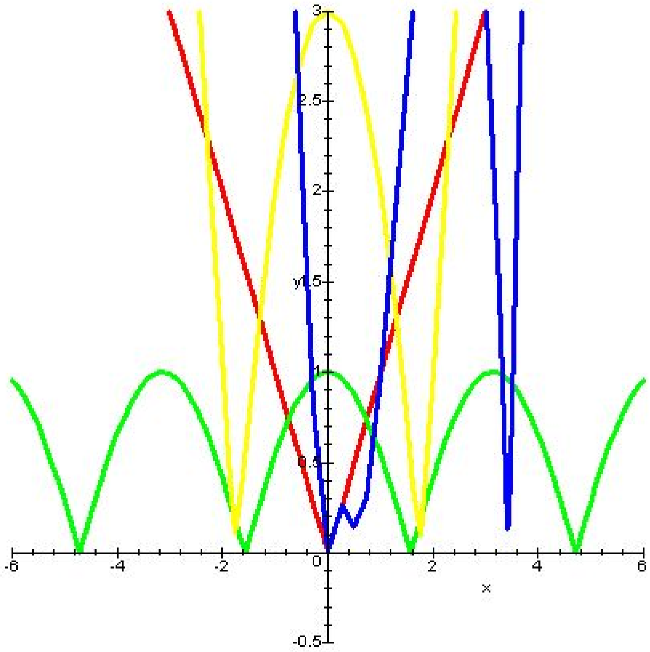
For example the plots with Maple™ 4.00b that we get with the command:

```
>plot([(x),(cos(x)),(x^2-3),(x^3-4*x^2+2*x)],x=-6..6,y=-4..3,
thickness=3);
```



and taking the absolute value:

```
>plot([abs(x),abs(cos(x)),abs(x^2-3),abs(x^3-4*x^2+2*x)]
,x=-6..6,y=-0.5..3,thickness=3);
```



- "Exponential functions":

$$f(x) = a^x \tag{7.1.74}$$

where the famous e^x (see section Functional Analysis page 2289) is only a special case and also $a \in \mathbb{R}$.

When $a \geq 0$ we have typically:

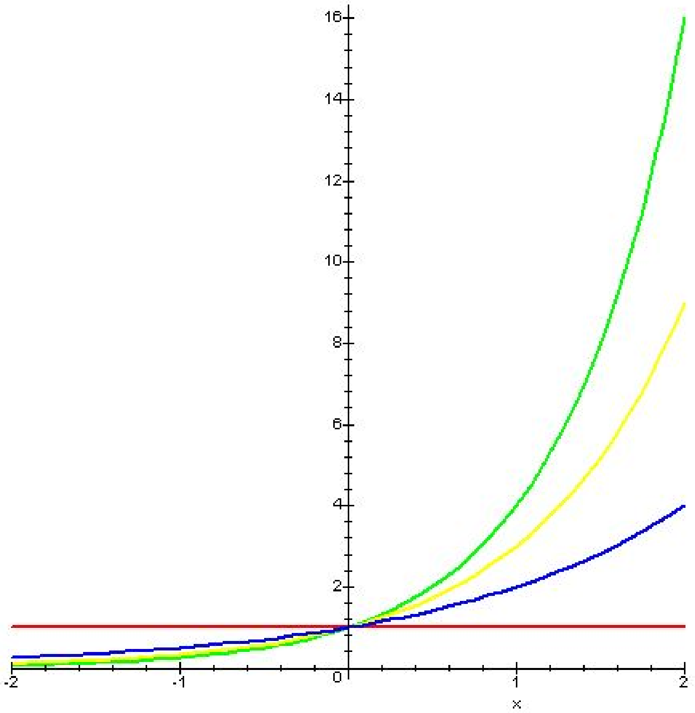


Figure 7.41: **Different plots of simple exponential functions** $(1^x, 2^x, 3^x, 4^x)$ **in Maple™ 4.00b**

If $a < 0, x \in \mathbb{R}$ the function is not defined. Indeed for $(-1)^{0.5} = \{\mathrm{i}, -\mathrm{i}\}$ therefore it is an application from $f: \mathbb{R} \mapsto \mathbb{C}^2$ and as far as we know there is no nice way to represent it visually and anyway this is not a function in the traditional way.

- "Logarithmic functions":

$$f(x) = \log_a(x) \tag{7.1.75}$$

with $a \in \mathbb{R}^+$ and that by construction of the logarithm (see further below) are of the type $f: \mathbb{R}^+ \mapsto \mathbb{R}$.

We have typically:

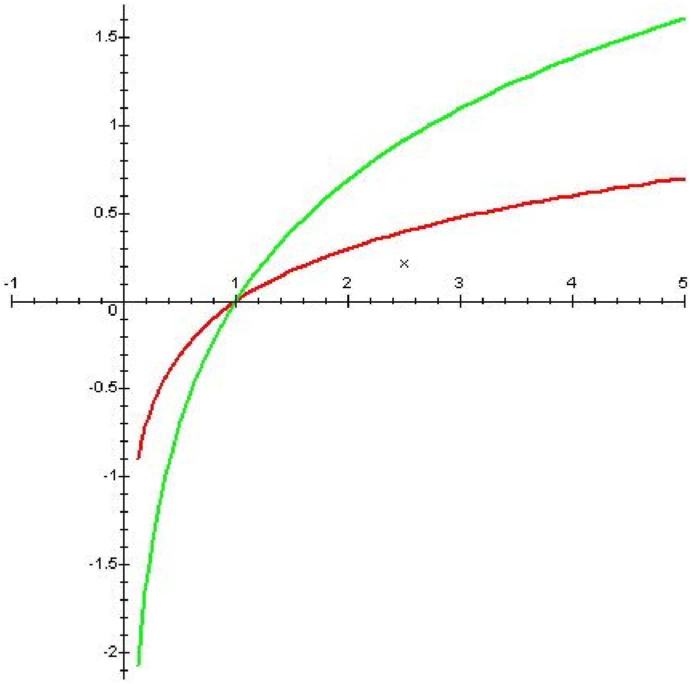

Figure 7.42: **Different plots of logarithm** $\ln(x)=\ln_e(x)$ **in green and** $\log_{10}(x)$ **in red with Maple™ 4.00b**

- "Periodic/Trigonometric functions":

$$y=\sin(x), y=\cos(x), y=\tan(x), y=\cot(x), y=\sec(x), y=\text{cosec}(x), \ldots \tag{7.1.76}$$

We already defined previously what is a periodic function. For the trigonometric functions the reader can see below a plot of the main one but for more details it is strongly recommended to read the section Trigonometry page 2503:

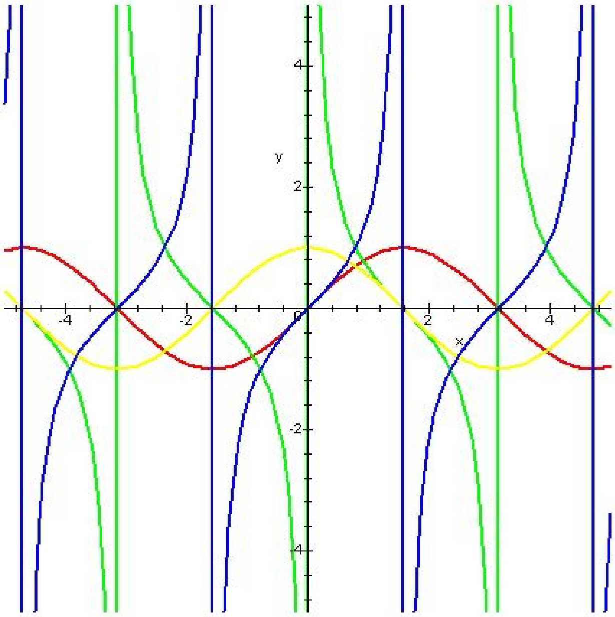

Figure 7.43: **Different plots of trigonometric functions in Maple™ 4.00b**

- "Polynomial functions":

$$f(x)=P(x)=a_n x^n+a_{n-1}x^{n-1}+\cdots+a_1x^1+a_0 \tag{7.1.77}$$

where as we already know $a_0, a_1, \ldots, a_n$ are constant numbers named "coefficients" and n is a positive integer that we name "degree of the polynomial" (voir section Calculus page 1368). Obviously this function is defined for all values of x, that is to say, it is define on an infinite interval.

If follows that power functions of the type x^m and linear functions of the type $f(x) = x$ are a subclass of polynomial for $m \in \mathbb{N}$.

We have already studied more deeply polynomials in the section Calculus with their main properties but let us give again the plot of some of them as recall:

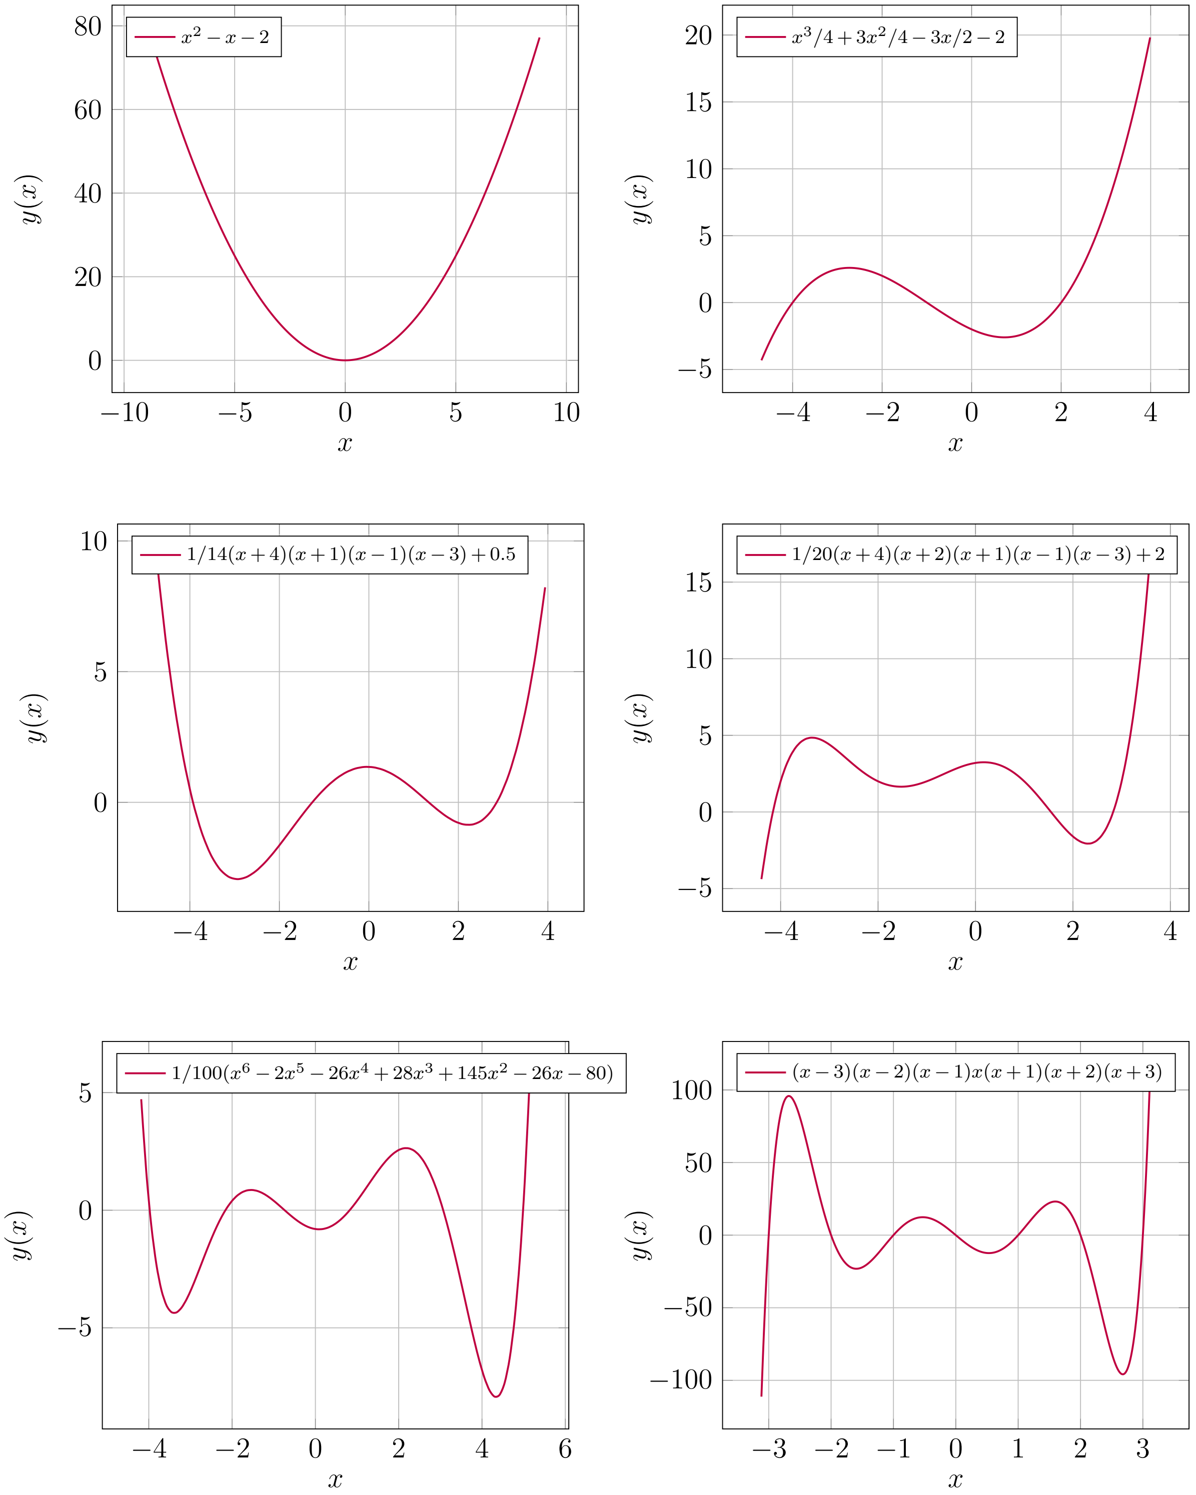

Figure 7.46: **Some polynomials plotted with TikZ**

We will see and study in this textbook some famous polynomials as the: Legendre polynomials (see section Quantum Chemistry page 6140), Bernoulli polynomials (see section Sequences and Series page 1672), Bernstein polynomials (see section Numerical Methods page 6570), Hermite polynomials (see section Functional Analysis page 2385), ...

- "Rational fractions" are polynomials divisions (see section Calculus page 1374):

$$f(x)=\frac{P(x)}{Q(x)}=\frac{a_nx^n+a_{n-1}x^{n-1}+\cdots+a_1x^1+a_0}{b_nx^n+b_{n-1}x^{n-1}+\cdots+b_1x^1+b_0} \tag{7.1.78}$$

Remark

Obviously two rational fractions are equal, if one is obtained from the other by multiplying the numerator and denominator by the same polynomial.

The rational function:

$$f(x)=\frac{x^3-2x}{2(x^2-5)} \tag{7.1.79}$$

is not defined at $x^2=5 \Leftrightarrow x=\pm\sqrt{5}$. It is asymptotic (see further below) to $\frac{x}{2}$ as x approaches infinity:

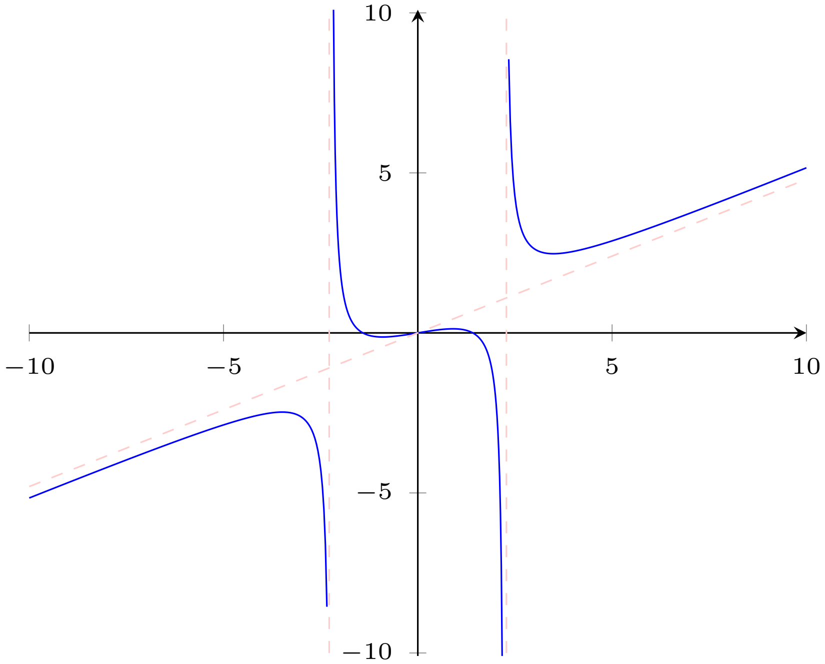

Figure 7.47: **Example of a rational function $f(x)=\frac{x^3-2x}{2(x^2-5)}$**

The rational function:

$$f(x)=\frac{x^2+2}{x^2+1} \tag{7.1.80}$$

is defined for all real numbers, but not for all complex numbers, since if x were a square root of -1 (i.e. the imaginary unit or its negative), then formal evaluation would lead to division by zero!

Remarks

A constant function is a rational function since constants are polynomials! Every polynomial function $f(x)=P(x)$ is a rational function with $Q(x)=1$. The power functions $f(x)=x^m$ are also rational functions when $m\in\mathbb{N}$.

- "Algebraic functions" are defined by the fact that the function $f(x)$ is the result of addition, subtraction, multiplication, division, of variables put to an integer or non-integer power. Therefore most of the functions defined previously can be included in this definition: linear functions, affine functions, power functions, polynomial functions, rational functions.
- "Piecewise functions" is a function defined by different formulas on different parts of its domain. The absolute value is a famous example of a piecewise-defined function because the formula changes with the sign of x:

$$f(x)=|x|:\begin{cases}-x & x<0\\ +x & x\geq 0\end{cases} \qquad (7.1.81)$$

  Another well-known example is the function that calculates pension contributions based on age. All countries (or companies) that have a pension concept have contribution amounts based on a piecewise continuous function.

- "Step functions" $f:[a,b]\in\mathbb{R}$ is defined if and only if there exists a subdivision $(a_i)_{0\leq i\leq n}$ of $[a,b]$ such that $a_0=a$ and $a_n=b$ and $(\lambda_0,\ldots,\lambda_n)\in\mathbb{R}^n$ such as:

$$\forall\in\{0,\ldots,n-1\}\,,\forall x\in]a_i,a_{i+1}[\Leftrightarrow f(x)=\lambda_i \qquad (7.1.82)$$

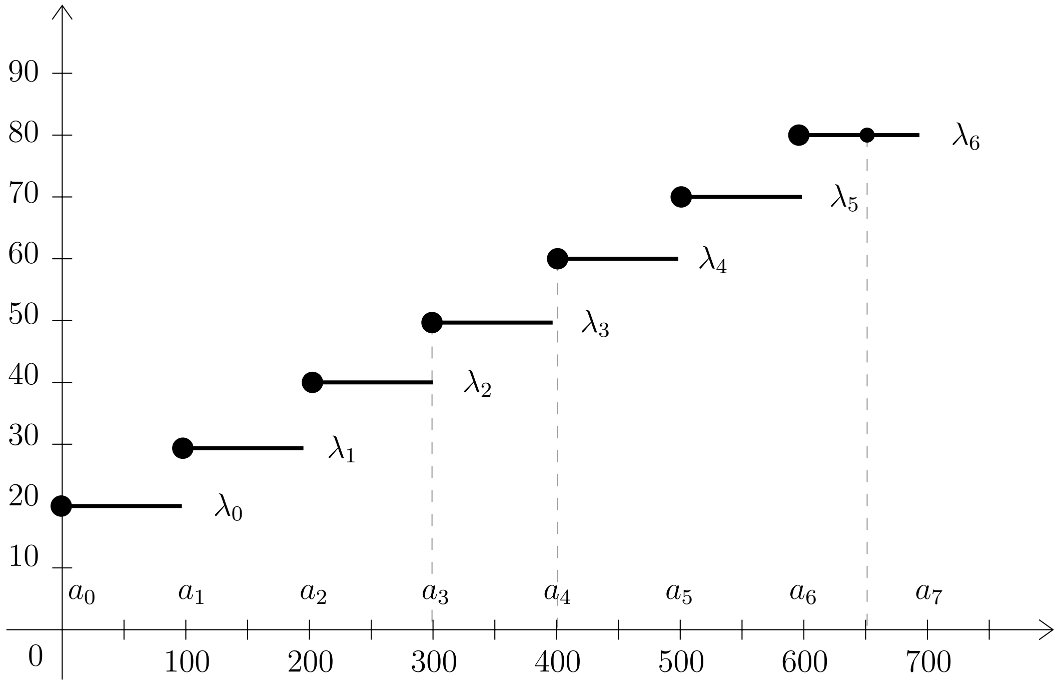

Figure 7.48: **Example of a step function**

Such functions can be found in signal processing and also in statistics for survival analysis.

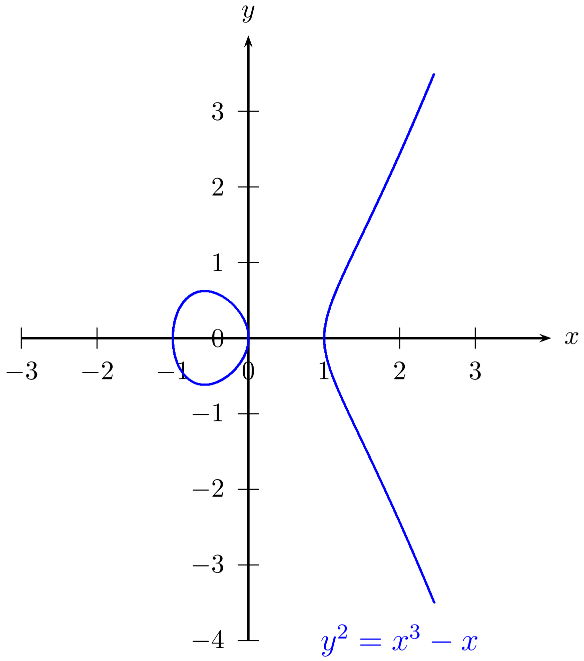
However, there are a very large number of other elementary functions that will meet in the individual sections of this textbook. Examples include the "Bessel functions" (see section Sequences and Series page 1768), the "Lipschitz functions" (see section Topology page 2457), the "Dirac functions" (see section Differential and Integral Calculus page 1569), the "distribution functions" (see section Statistics page 633), the "Euler gamma function" (see section Differential and Integral Calculus page 1574), etc. The reader will notice that the Dirac function also belongs to the family of distribution functions.

Here is a quite good summary of most elementary functions (non exhaustive but still good!):

Constant  $f(x)=c^{te}$	Linear  $f(x)=x$	Absolute Value  $f(x)=\|x\|$	Quadratic  $f(x)=x^2$
Square root  $f(x)=\sqrt{x}$	Cubic  $f(x)=x^3$	Cube root  $f(x)=\sqrt[3]{x}$	Inverse  $f(x)=\frac{1}{x}$
Rational  $f(x)=\frac{1}{x^2}$	Logarithmic  $f(x)=\ln(x)$	Exponential  $f(x)=e^x$	Greatest Integer (step function)  $f(x)=[x]$
Polynomial  $f(x)=1/100(x^6-2x^5-26x^4+\ldots$	Binomial distribution  $f(x)=\mathcal{B}(N,k)$	Gaussian distribution  $f(x)=e^x$	Poisson distribution  $f(x)=\mathcal{P}(\mu,k)$
Trigonometric Functions $\rightarrow$	Sine  $f(x)=\sin(x)$	Cosine  $f(x)=\cos(x)$	Tangent  $f(x)=\tan(x)$

Table 7.4: **A summary of some elementary college level functions**

If once you see the plot like that one of an elliptic curve (mathematical tool used in cryptography):



You have to avoid to name that a "function". Indeed, by definition, a "function" has to pass the "vertical line test": The vertical line test is a method that is used to determine whether a given relation is a function or not. The approach is rather simple. Draw a vertical line cutting through the graph of a relation, and then observe the points of intersections. The vertical line test supports the definition of a function. That is, every x-value of a function must be paired to a single y-value. If a vertical line intersects the graph of a relation at exactly one point, it implies that a single x-value is only paired to a unique value of y.

The definition of an "elliptic curve" is the set of all points such that $y^2 = x^3 + ax + b$. That is, $E_{a,b,c} \equiv \{(x, y) : y^2 = x^3 + ax + b\}$.

Let a solution $(x_0, y_0) \in E_{a,b,c}$. then by definition $y_0^2 = x_0^3 + ax_0 + b$. So, $(-y_0)^2 = y_0^2 = x_0^3 + ax_0 + b$. Therefore, $(x_0, -y_0) \in E_{a,b,c}$. Hence, this will fail the vertical line test at $x = x_0$.

That is to say, an elliptic curve cannot be a function!

The graph of relation $yRx \Leftrightarrow y^2 = x^3 - x$ above (as we can't use the word "function" in this case...) is said to be "disconnected"; more specifically, it consists of two "connected components". This is a general topological concept that can be applied to all sets, not just to graphs of relations.

7.1.2.1 Limits and Continuity of functions

We will now consider ordered variables of a special type, which we define by the relation "the variable tends to a limit." In what will follow, the concept of limit of a variable will play a fundamental role, being intimately related to the basic notions of mathematical analysis, derivatives, integrals, etc.

Definition (#7.1.273): The number a is named the "limit" of variable magnitude x, if for any arbitrarily small positive number ε we have:

$$|x-a|<\varepsilon \tag{7.1.83}$$

If the number a is the limit of the variable x, we say that "x tends to the limit a".

We can also define the concept of limit from geometrical considerations (this can help to better understand ... but not always ...):

The constant number a is the limit of the variable x, if for any given neighbourhood, no matter how small, of center a and of radius ε, we can find a value x such that all the points corresponding to the following values of the variable belong to this neighbourhood (notions that we defined earlier). We represent geometrically this as:

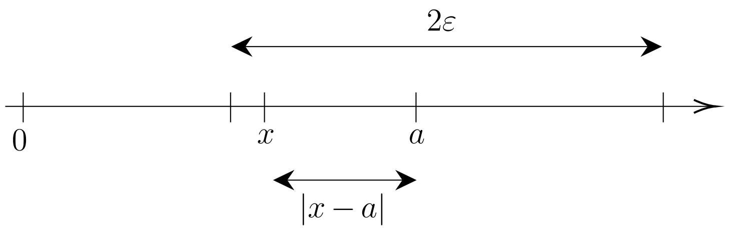


Figure 7.49: **Geometric concept of limit in $\mathbb{R}^3$**

Remarks

R1. It should be trivial that the limit of a constant value is equal to this constant, since the inequality $|x-c^{te}|=|c^{te}-c^{te}|=0<\varepsilon$ is always satisfied for an arbitrary $\varepsilon>0$.

R2. Not all variable have limits. For example $y=\sin(x)$ as this trigonometric function fluctuates between $[-1,+1]$ from $[-\infty,+\infty]$.

Definition (#7.1.274): A variable x tends to infinity if for any positive chosen M, we indicate one value of x from which all successive values of the variable x (values in the neighbourhood of the previous chosen value) satisfy the inequality $|x|>M$. Formally:

$$|x|\rightarrow+\infty,\forall M>0: \quad |x|>M \tag{7.1.84}$$

- A variable x "tends to $+\infty$" if for any positive chosen $M>0$, we indicate one value of x from which all the successive values of the variables x satisfy the inequality $M<x$.

  It is typically the type of consideration that we have for divergent sequences (divergent to infinity) where for a given term of value M of the sequence all the other terms are greater than M:

$$x \to +\infty, \forall M > 0: \quad x > M \tag{7.1.85}$$

- A variable x "tends to $-\infty$" if for any negative chosen $M < 0$, we indicate one value of x from which all the successive values of the variable x satisfy the inequality $x < M$:

$$x \to -\infty, \forall M < 0: \quad x < M \tag{7.1.86}$$

Definition (#7.1.275): Given $y = f(x)$ a function defined in a neighbourhood of a or on some point of this neighbourhood. The function $y = f(x)$ tends to the limit L (that is to say $y \to L$) when x tends to a (that is to say $x \to a$) if for any positive number ε as small as possible, we can indicate a positive number δ such that all x different from a satisfying the inequality $0 < |x - L| < \delta$ also satisfy $|f(x) - L| < \varepsilon$. Formally a function has a limit L on L when in a domain E if:

$$\boxed{\lim_{x \to a} = L \Leftrightarrow \forall x \in E, \exists L, \forall \delta > 0, \forall \varepsilon > 0: \quad 0 < |x - a| < \delta \Rightarrow |f(x) - L| < \varepsilon} \tag{7.1.87}$$

The relation above is named the "epsilon-delta definition of limit or "(ε, δ) definition of limit".

The inequality $0 < |x - a| < \delta$ gives the possibility to have the distance from which we come with our x without taking care of the direction (left or right) as we take for measurement of distance the absolute values. Indeed on a system of axis representing ordinates values, we can, for a given value, coming from the left or from the right (if necessary you can imagine a bus coming to a bus stop that can from the left or from the right only since the absolute distance from it to the bus stop is less than or equal to δ).

If L is the limit of the function $f(x)$ when $x \to a$ we then write in this textbook in any case:

$$\lim_{x \to L} f(x) = L \tag{7.1.88}$$

Obviously the above definition is available when $a = \pm\infty$ or/and $L = \pm\infty$!

To define the direction from which we come from by applying the limit, we use a special notation (recall that this will give us the information of which side of the road comes our bus from...). Thus, if $f(x)$ tends towards the limit L_1 when x approaches a number a by taking only values smaller than a, then we write:

$$\lim_{x \to a_-} f(x) = L_1 \tag{7.1.89}$$

(notice the small $-$ subscript) and we name L_1 the "left limit" of the function $f(x)$ at point a (because remember that the horizontal axis goes from left to right from $-\infty$ to $+\infty$, so small values compared to a given value, are on the left).

If x takes values greater than a, then we will write:

$$\lim_{x \to a_+} f(x) = L_2 \tag{7.1.90}$$

(notice the small $+$ subscript) and we name L_2 the "right limit" of the function $f(x)$ at point a.

In the figure below we have for example:

$$\lim_{x\rightarrow -3_+} f(x)=-\infty \qquad \lim_{x\rightarrow -3_-} f(x)=+\infty \tag{7.1.91}$$

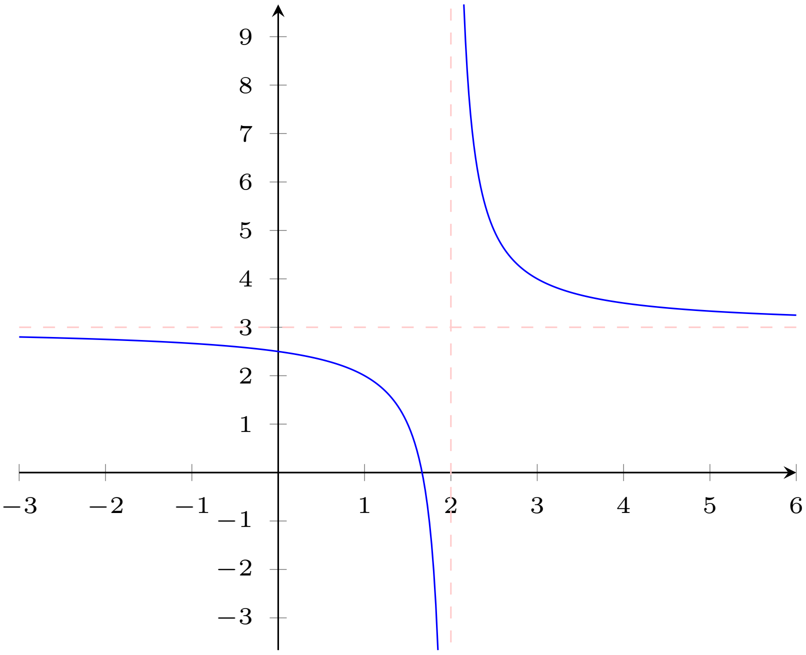

Figure 7.50: Left and right limit examples

It is not always easy (or even possible) to calculate limits of some functions. Let us see some typical examples:

✍**Examples:**

E1. Let us prove that:

$$\lim_{x\rightarrow +\infty}\dfrac{x+1}{x}=1 \tag{7.1.92}$$

is true. For this purpose we have to prove that for any small ε the inequality:

$$\left|1+\dfrac{1}{x}-1\right|<\varepsilon \tag{7.1.93}$$

will be satisfied as soon as $|x|>M$ where M is defined by the choice of ε. The previous inequality is obviously equal to:

$$\left|\dfrac{1}{x}\right|<\varepsilon \tag{7.1.94}$$

which is satisfied if we have x:

$$\left|x\right|>\dfrac{1}{\varepsilon}=M \tag{7.1.95}$$

We admit that the example and the method can be discussed.... But in fact it is only an application of the l'Hôpital's rule (ratio of the derivatives) already proved in the section of Differential and Integral Calculus at page 1461. The reader must also know that we will see also other techniques to determine limits further below with better examples.

E2. Now using Taylor series and change of variables consider we want to calculate:

$$\lim_{x\to+\infty}\sqrt{(x^2+5x)}-x \tag{7.1.96}$$

The method is quite intuitive. Indeed, first we do a change of variable:

$$\begin{aligned}\lim_{x\to+\infty}\sqrt{(x^2+5x)}-x&=\lim_{x\to+\infty}x\sqrt{1+\frac{5}{x}}-x\\&=\lim_{x\to+\infty}x\left(\sqrt{1+\frac{5}{x}}-1\right)=\lim_{y\to 0}\frac{1}{y}\left(\sqrt{1+5y}-1\right)\end{aligned} \tag{7.1.97}$$

Now consider the Taylor series about $x=0$ for the function $f(x)=\sqrt{1+ax}$. We have:

$$f'(x)=\frac{1}{2}a(1+ax)^{-1/2}\qquad f''(x)=-\frac{1}{4}(1+ax)^{-3/2} \tag{7.1.98}$$

Which gives:

$$f(x)\cong 1+\frac{1}{2}ax+\mathcal{O}(x^2) \tag{7.1.99}$$

as a Taylor expansion about $x=0$. Applying this to our limit we see that:

$$\lim_{y\to 0}\frac{1}{y}\left(\sqrt{(1+5y)}-1\right)\cong\lim_{y\to 0}\frac{1}{y}\left(1+\frac{5}{2}y+\mathcal{O}(y^2)-1\right)=\lim_{y\to 0}\frac{1}{y}\left(\frac{5}{2}+\mathcal{O}(y)\right)=\frac{5}{2} \tag{7.1.100}$$

E3. We want to calculate the limit of:

$$\lim_{x\to+\infty}\arctan(x) \tag{7.1.101}$$

How can we deal with something like this? An idea is the to remember that it also implicitly means:

$$\arctan(+\infty)=\theta \tag{7.1.102}$$

Hence:

$$+\infty=\tan(\theta) \tag{7.1.103}$$

And to answer what is the value of θ, we refer to the plot of the function $\tan(\theta)$ and we see then that the first corresponding value is $\pi/2$, therefore:

$$\lim_{x\to+\infty}\arctan(x)=\frac{\pi}{2} \tag{7.1.104}$$

The signification of the symbols $x \to -\infty$ and $x \to +\infty$ makes obvious the signification of the expressions:

$$f(x) \text{ tends to } L \text{ when } x \to +\infty \tag{7.1.105}$$

and:

$$f(x) \text{ tends to } L \text{ when } x \to -\infty \tag{7.1.106}$$

that we denote formally by:

$$\lim_{x \to +\infty} f(x) = L \quad \text{and} \quad \lim_{x \to -\infty} f(x) = L \tag{7.1.107}$$

We have defined the case where the function $f(x)$ tends to a certain limit L when $x \to a_{+,-}$ or $x \to \pm\infty$. Now let us consider the case where the function tend to infinity when the variable x change in a certain way.

We then have typically and obviously:

$$\lim_{x \to a} f(x) = +\infty \qquad \text{or} \qquad \lim_{x \to a} f(x) = +\infty \tag{7.1.108}$$

Or when we need to indicate the direction:

$$\lim_{x \to a_{+,-}} f(x) = +\infty \qquad \text{or} \qquad \lim_{x \to a_{+,-}} f(x) = +\infty \tag{7.1.109}$$

If the function $f(x) \to +\infty$ when $a \to +\infty$ then we write:

$$\lim_{x \to +\infty} f(x) = +\infty \tag{7.1.110}$$

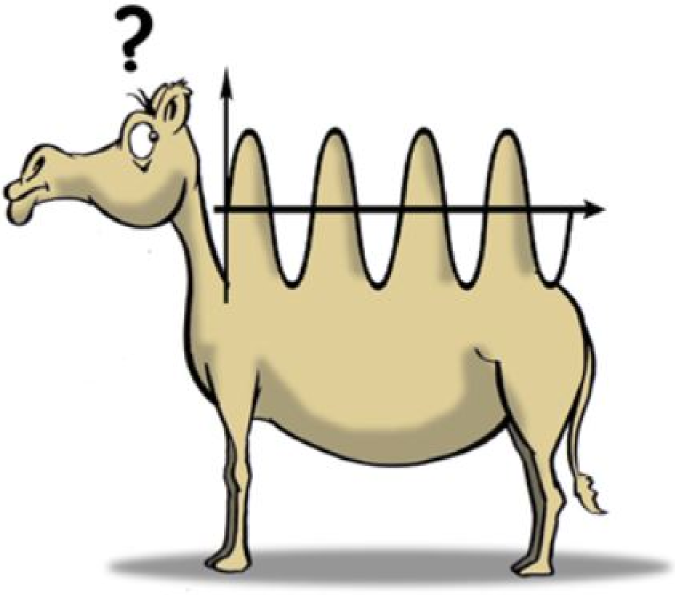
And as we have four possibilities for the sign, we write:

$$\lim_{x \to \pm\infty} f(x) = \pm\infty \tag{7.1.111}$$

that is to say the four following possibilities:

$$\lim_{x \to +\infty} f(x) = +\infty, \; \lim_{x \to -\infty} f(x) = +\infty, \; \lim_{x \to +\infty} f(x) = -\infty, \; \lim_{x \to -\infty} f(x) = -\infty \tag{7.1.112}$$

And once again don't forget as we already mentioned before that some function such as for example $f(x) = \sin(x)$ don't have any finite limit when $x \to \pm\infty$. Then we say that the function is just "bounded" (see section Set Theory page 282).



Now that we've roughly an overview of the concept of limit, we will give an extremely important definition that has a very important place of many areas of high-level mathematics, theoretical physics and computing science (numerical methods).

Definition (#7.1.276): Given a function $f(x)$ and one of its subdomain (or whole one) E (most of time $E \subseteq \mathbb{R}$) and $x_0 \in E$, we say that we have a "continuous function" on x_0 if and only if:

$$\lim_{x \to x_0} f(x) = f(x_0) \tag{7.1.113}$$

That is to say more formally (you have to be able to read the fact that we are going close in an infinitely small way of a limit and this allows the continuity):

$$\boxed{\forall x_0 \in E \forall \varepsilon > 0 \exists \delta > 0 \forall x \in E: \quad |x - x_0| < \delta \Rightarrow |f(x) - f(x_0)| < \varepsilon} \tag{7.1.114}$$

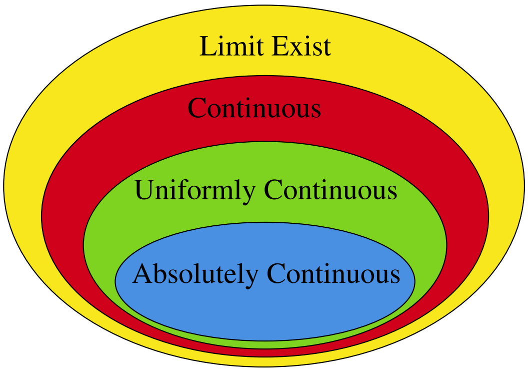
named the "epsilon-delta continuity" or "(ε, δ) continuity".

Remember that $|x - x_0| < \delta \Rightarrow |f(x) - f(x_0)| < \varepsilon$ says when the distance of the input relative to x_0 is small, the distance of the output relative to $f(x_0)$ must be small. How small? Arbitrarily small! If $|a - b| < \varepsilon$ for all $\varepsilon > 0$, then $a = b$! The only way $|x - x_0|$ can be small is if x was actually really close to x_0. That is the purpose of δ! To measure how close we are to x_0. So when we move close to x_0, we should expect to move closer to $f(x_0)$!

In other words: a function is "continuous" if for every point x_0 in the domain E, we can make the images of that point ($f(x_0)$) and another point ($f(x)$) arbitrarily close (of a distance ε) if we move the other point (x) close enough (distance δ) to our given point (x_0).

Caution! Some people have trouble understanding the difference between the definition of a limit of a function and definition of continuity. The difference is that for the limit $0 < |x - L| < \delta$ means that we are not imposing any conditions on the function for $x = L$, while in the definition of continuity, we have $|x - x_0| < \delta$. The difference is that in the definition of continuity at x_0, we insist that the function also be defined at $x = x_0$, but we don't in the definition of limit!

The latter relation will be generalized a little bit in the section of Topology and completed with the concept of... "uniform continuity" (that can itself be generlazied by "absolute continuity" but that's out of the scope of this textbook)!



Remarks

R1. f is "continuous on the left" or respectively "continuous on the right", if we add to the definition above the condition $x > x_0$, respectively $x < x_0$.

R2. A continuous function with a continuous inverse function is named a "homeomorphism".

R3. Instead of saying when it is necessary that a function is not continuous on x_0 or on a given domain, some practitioners prefer to say that the function has an "oscillation".

We have the following trivial corollaries:

C1. $f(x)$ is continuous on x_0 if and only if $f(x)$ is continuous on the left and on the right of x_0.

C2. $f(x)$ is continuous on E if and only if $f(x)$ is continuous on any point of E.

Let $f(x)$ and $g(x)$ be two functions that are continuous at x_0, then we have the following properties (we will prove some of them only on readers requests!):

P1. $f(x)+g(x)$ (also denoted $(f+g)(x)$) is also epsilon-delta continuous at x_0.

As a reader requested the proof of that claim, let's do it!

If $f(x)$ and $g(x)$ are epsilon-delta continuous at a, then $(f+q)(x)$ (shortcut notation for $f(g)+g(x)$) is also epsilon-delta continuous at a.

So far a given $\varepsilon>0$ we have to find $\delta>0$ so if $0|x-a|<\delta$, then $|(f+q)(x)-(f+g)(a)|<\varepsilon$.

First we have obviously:

$$|f(x)+g(x)-(f(a)+g(a))|=|f(x)+g(x)-f(a)-g(a)| \tag{7.1.115}$$

But because of the triangle inequality of absolute value we have:

$$|f(x)-f(a)+g(x)-g(a)|\leq|f(x)-f(a)|+|g(x)-g(a)| \tag{7.1.116}$$

As $f(x)$ and $g(x)$ are assumed epsilon-delta continuous, i.e. $|f(x)-f(a)|<\varepsilon$ when $<|x-a|<\delta_f$ and $|g(x)-f(a)|<\varepsilon$ when $|x-a|<\delta_g$ we have therefore for the previous relation:

$$\underbrace{|f(x)-f(a)|}_{\leq\varepsilon}+\underbrace{|g(x)-g(a)|}_{\leq\varepsilon}\leq 2\varepsilon \tag{7.1.117}$$

Ok you have understand so far how we get that last relation and especially the 2ε, let us now reverse the reasoning! We have from the latter:

$$\begin{gathered}|f(x)-f(a)|+|g(x)-g(a)|<2\varepsilon\\ |f(x)-f(a)+g(x)-g(a)|<2\varepsilon\end{gathered} \tag{7.1.118}$$

and let δ_h be defined as $\min(\delta_g, \delta_f)$ and $h(x)$ be defined as $f(x)+g(x)$. Therefore:

$$|h(x)-h(a)|<2\varepsilon \tag{7.1.119}$$

We can obviously replace δ_f and δ_g by δ_h to get:

$$|f(x)-f(a)|<\varepsilon \text{ when } |x-a|<\delta_h \text{ and } |g(x)-g(a)|<\varepsilon \text{ when } |x-a|<\delta_h \tag{7.1.120}$$

Since:

$$|f(x)-f(a)|+|g(x)-g(a)|<2\varepsilon \tag{7.1.121}$$

that we have derived just before is true when $0<|x-a|<\delta_h$, we can find a δ_h for every value of 2ε.

Finally that means that for every $2\varepsilon>0$ there is a $\delta>0$ such that $|x-a|<\delta \Longrightarrow |h(x)-h(a)|<2\varepsilon$ and for every 2ε there exists an ε so for every ε there exists a δ.

P2. $f(x)-g(x)$ (also denoted $(f-g)(x)$) is also epsilon-delta continuous at x_0.

The proof is immediate from the previous proof as we just have to put $-g(x)=h(x)$ (we will admit that the negative sign of a epsilon-delta continuous function is still epsilon-delta continuous without proof) and therefore we fall back on a sum $f(x)+h(x)$.

P3. $c^{te}f(x)$ is also epsilon-delta continuous at x_0.

P4. $f(x)\cdot g(x)$ (also denoted $fg(x)$) is also epsilon-delta continuous at x_0.

Let $f,g:\mathbb{R}\mapsto\mathbb{R}$ be given such that f and g are epsilon-delta continuous. Let $u:\mathbb{R}\mapsto\mathbb{R}$ be defined by $u(x)=f(x)g(x)$. We want to show: u is epsilon-delta continuous, that is, for all $x_0\in\mathbb{R}$, for every $\varepsilon>0$, there exists some $\delta>0$ such that for all $x\in\mathbb{R}$ with $|x-x_0|<\delta$, $|u(x)-u(x_0)|<\varepsilon$.

We have first using a firs time the properties of the triangle inequality and of the multiplicativeness of the absolute value:

$$\begin{aligned}|f(x)g(x)-f(x_0))g(x_0))|&=|f(x)g(x)-f(x_0))g(x)+f(x_0))g(x)-f(x_0)g(x_0))|\\&\leq|f(x)g(x)-f(x_0))g(x)|+|f(a)g(x)-f(x_0)g(x_0)|\\&=|\,(g(x)[f(x)-f(x_0)]|+|f(x_0)[g(x)-g(x_0)]\,|\\&=|g(x)|\cdot|f(x)-f(x_0)|+|f(x_0)|\cdot|g(x)-g(x_0)|\end{aligned} \tag{7.1.122}$$

Now the $|f(x)-f(x_0)|$ and $|g(x)-g(x_0)|$ terms are good, since $f(x)$ and $g(x)$ are epsilon-delta continuous at x_0. Moreover, the $|g(x_0)|$ term is good since it is constant!

The problem is $g(x)$. Let's see if we can do something clever to get rid of it?! We can try to rewrite is using the triangular inequality (again...) of the absolute value:

$$|g(x)|=|g(x)-g(x_0)+g(x_0)|\leq|g(x)-g(x_0)|+|g(x_0)| \tag{7.1.123}$$

Now remember that $g(x)$ is continuous, therefore $\forall x\in\mathbb{R}$ with $|x-x_0|<\delta$ we have:

$$|g(x)-g(x_0)|<\varepsilon_g \tag{7.1.124}$$

Therefore we can rewrite the prior-previous inequality as:

$$|g(x)| \leq \underbrace{|g(x)-g(x_0)|}_{<\varepsilon_g}+|g(x_0)|<\varepsilon_g+|g(x_0)| \tag{7.1.125}$$

So we get finally a relationship that may help us to get rid of the $g(x)$ that mades us problem earlier:

$$|g(x)|<\varepsilon_g+|g(x_0)| \tag{7.1.126}$$

And we can inject it in the step that was making us troubles, that is:

$$\begin{aligned}|f(x)g(x)-f(x_0)g(x_0)| &\leq |g(x)|\cdot|f(x)-f(x_0)|+|f(x_0)|\cdot|g(x)-g(x_0)|\\ &<(\varepsilon_g+|g(x_0)|)\cdot|f(x)-f(x_0)|+|f(x_0)|\cdot|g(x)-g(x_0)|\end{aligned} \tag{7.1.127}$$

ie:

$$|f(x)g(x)-f(x_0)g(x_0)<(|g(x_0)|+\varepsilon_g)\cdot|f(x)-f(x_0)|+|f(x_0)|\cdot|g(x)-g(x_0)| \tag{7.1.128}$$

But as $f(x)$ and $g(x)$ are epsilon-delta continuous we know that we have $\varepsilon_f,\varepsilon_g$ that exist such that:

$$|f(x)-f(x_0)|<\varepsilon_f \qquad \text{and} \qquad |g(x)-g(x_0)|<\varepsilon_g \tag{7.1.129}$$

Therefore:

$$\begin{aligned}|f(x)g(x)-f(x_0)g(x_0)| &<(|g(x_0)|+\varepsilon_g)\cdot|f(x)-f(x_0)|+|f(x_0)|\cdot|g(x)-g(x_0)|\\ &=(|g(x_0)|+\varepsilon_g)\cdot\varepsilon_f+|f(x_0)|\cdot\varepsilon_g\end{aligned} \tag{7.1.130}$$

We may stop here and the proof is finished as we have only constant terms that can be infinitely small. However mathematicians like to finish[3] the proof with only one term on the right hand side of the equality that looks like a single ε. So obviously as we have two terms that adds together we should have something that looks like $\varepsilon/2+\varepsilon/2=\varepsilon$. For that purpose, mathematicians get rid of the ugly $(|g(x_0)|+\varepsilon_g)\cdot\varepsilon_f$ by defining (they absolutely can its not forbidden):

$$\varepsilon_f=\frac{\varepsilon}{2(|g(x_0)|+\varepsilon_g)} \tag{7.1.131}$$

Therefore we have:

$$\begin{aligned}|f(x)g(x)-f(x_0)g(x_0)| &<(|g(x_0)|+\varepsilon_g)\cdot\varepsilon_f+|f(x_0)|\cdot\varepsilon_g\\ &=(|g(x_0)|+\varepsilon_g)\cdot\frac{\varepsilon}{2(|g(x_0)|+\varepsilon_g)}+|f(x_0)|\cdot\varepsilon_g\\ &=\frac{\varepsilon}{2}+|f(x_0)|\cdot\varepsilon_g\end{aligned} \tag{7.1.132}$$

---

[3] There is a deep reason for that! If we can't finish the proof that way the function will be sure "continuous" but not "uniform continuous" (that's a property most engineers don't care about). For example x^2 or e^x are two functions that are epsilon-delta continuous but not uniform continuous. The impact is out of the scope of this textbook dedicated for reminder to engineers.

Ok it looks better however for mathematicians its still ugly because of the term $|f(x_0)|\cdot\varepsilon_g$. So you may thing we should simple put:

$$\varepsilon_g=\frac{\varepsilon}{2|f(x_0)|} \tag{7.1.133}$$

and it's done as the sum of the two terms would give ε! But it's not!!! Because if in the special case where we may have $|f(x_0)|=0$ then we would have a division by zero! So an idea would be to add a value, that we will denote $\Delta\neq 0$ such that the denominator can never be zero. Let us put for example:

$$\varepsilon_g=\frac{\varepsilon}{2|f(x_0)|+\Delta} \tag{7.1.134}$$

However if we do that we don't have:

$$|f(x_0)|\frac{\varepsilon}{2|f(x_0)|+\Delta}\neq\frac{\varepsilon}{2} \tag{7.1.135}$$

We see obviously that the only solution to get the expected (pretty) result would be to add a term in the firs factor such that:

$$\left(|f(x_0)|+\underbrace{\frac{\Delta}{2}}_{\text{we add that}}\right)\frac{\varepsilon}{2|f(x_0)|+\Delta}=\frac{\varepsilon}{2} \tag{7.1.136}$$

However... can we do that? In other words, can we write something like this (if we come some steps backward):

$$|f(x)g(x)-f(x_0)g(x_0)|\overset{?}{<}(|g(x_0)|+\varepsilon_g)\cdot\varepsilon_f+\left(|f(x_0)|+\frac{\Delta}{2}\right)\cdot\varepsilon_g \tag{7.1.137}$$

And we see obviously that the answer is YES if and only if $\Delta>0$.

Therefore to summarize all we went through, we have:

$$\begin{aligned}|f(x)g(x)-f(x_0)g(x_0)|&=|f(x)g(x)-f(x_0)g(x)+f(x_0)g(x)-f(x_0)g(x_0)|\\&\leq|f(x)g(x)-f(x_0)g(x)|+|f(x_0)g(x)-f(x_0)g(x_0)|\\&=|g(x)(f(x)-f(x_0)|+|f(x_0)(g(x)-g(x_0))|\\&=|g(x)|\cdot|f(x)-f(x_0)|+|f(x_0)|\cdot|g(x)-g(x_0)|\\&<(|g(x_0)|+\varepsilon)\cdot\frac{\varepsilon}{2(|g(x_0)|+\varepsilon)}+|f(x_0)|\cdot|g(x)-g(x_0)|\\&\leq\frac{\varepsilon}{2}+|f(x_0)|\cdot\frac{\varepsilon}{2|f(x_0)|+\Delta}\\&<\frac{\varepsilon}{2}+\left(|f(x_0)|+\frac{\Delta}{2}\right)\cdot\frac{\varepsilon}{2|f(x_0)|+\Delta}\\&=\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon\end{aligned} \tag{7.1.138}$$

And that's the pretty final result mathematicians like to have!

P5. $|f(x)|$ is also epsilon-delta continuous at x_0.

Let $\varepsilon > 0$ be given. Then, since $f(x)$ is continuous at x_0, there is $\delta > 0$ such that if $|x - x_0| < \delta$, then $|f(x) - f(x_0)| < \varepsilon$.

With that same δ, if $|x - x_0| < \delta$, then by the reverse triangle inequality (see section Arithmetic Operators page 326), which says $|a-b| \geq ||a| - |b||$, we have:

$$||f(x)| - |f(x_0)|| \leq |f(x) - f(x_0)| < \varepsilon \tag{7.1.139}$$

Therefore $|f(x)|$ is epsilon-delta continuous at x_0

P6. $1/f(x)$ is also epsilon-delta continuous at x_0.

This time we need to estimate:

$$\left|\frac{1}{f(x)} - \frac{1}{f(x_0)}\right| = \left|\frac{f(x_0) - f(x)}{f(x)f(x_0)}\right| = \frac{|f(x) - f(x_0)|}{|f(x)||f(x_0)|} \tag{7.1.140}$$

The $|f(x) - f(x_0)|$ term is good, and the $|f(x_0)|$ term is good as well (since it is constant).

The only term we need to control is the $|f(x)|$ term.

Since we want $\frac{1}{|f(x)|} <$ something, we need $|f(x)| >$ something!

Using the inverse triangular inequality of the absolute value, we know that we have:

$$|f(x) - f(x_0)| \geq ||f(x)| - |f(x_0)|| \tag{7.1.141}$$

But as $|a| \geq -a$ for all a, then we can write:

$$|f(x) - f(x_0)| \geq ||f(x)| - |f(x_0)|| \geq -(|f(x)| - |f(x_0)|) = |f(x_0)| - |f(x)| \tag{7.1.142}$$

Therefore we get:

$$|f(x_0)| - |f(x)| \leq |f(x) - f(x_0)| \tag{7.1.143}$$

But now keep in mind that as $f(x)$ is continuous there is a δ_1 such that if $|x - x_0| < \delta_1$, then $|f(x) - f(x_0)| < \varepsilon_1$. So let us choose empirically:

$$\varepsilon_1 = \frac{|f(x_0)|}{2} \tag{7.1.144}$$

Then with this choice (keep in mind that this inequality is valid if and only if $|x - x_0|$ is small enough and $f(x) \neq 0$ and that we may choose something else than 2 at the denominator but we made that choice because we will have a nice result at the end!):

$$|f(x_0)| - |f(x)| \leq |f(x) - f(x_0)| < \frac{|f(x_0)|}{2} \tag{7.1.145}$$

And therefore by rearranging:

$$|f(x)| > |f(x_0)| - \frac{|f(x_0)|}{2} = \frac{|f(x_0)|}{2} > 0 \tag{7.1.146}$$

Hence:

$$\frac{1}{|f(x)|}<\frac{2}{|f\left(x_0\right)|} \tag{7.1.147}$$

And that good it's want we wanted remember! We wanted $\frac{1}{|f(x)|}<$ something, we needed $|f(x)|>$ something! So now we have it!

Therefore:

$$\begin{aligned}\left|\frac{1}{f(x)}-\frac{1}{f\left(x_0\right)}\right| &= \frac{|f(x)-f\left(x_0\right)|}{|f(x)|\,|f\left(x_0\right)|}\\ &\leq \frac{|f(x)-f\left(x_0\right)|}{|f\left(x_0\right)|}\left(\frac{2}{|f\left(x_0\right)|}\right)\\ &= |f(x)-f\left(x_0\right)|\left(\frac{2}{|f\left(x_0\right)|^2}\right)\\ &?<\varepsilon\end{aligned} \tag{7.1.148}$$

So are we stuck? No! Because for the last line above we see that it would be just enough to have:

$$|f(x)-f\left(x_0\right)|<\frac{\varepsilon}{2}|f\left(x_0\right)|^2 \tag{7.1.149}$$

And this is something we can also choose as $f(x)$ is epsilon-delta continuous and $f(x)\neq 0$.

Therefore we can write the complete proof starting from here now that we have all the tools! :

Let $\varepsilon>0$ be given.

Then, since $f(x)$ is epsilon-delta continuous at x_0, there is $\delta_1>0$ such that if $|x-x_0|<\delta_1$, then $|f(x)-f\left(x_0\right)|<\frac{|f(x_0)|}{2}$, which implies $|f(x)|>\frac{|f(x_0)|}{2}$, and therefore $\frac{1}{|f(x)|}<\frac{2}{|f(I_0)|}$.

Moreover, since $f(x)$ is epsilon-delta continuous at x_0, there is $\delta_2>0$ such that if $|x-x_0|<\delta_2$, then $|f(x)-f\left(x_0\right)|<\frac{\varepsilon}{2}|f\left(x_0\right)|^2$.

Let $\delta=\min\left\{\delta_1,\delta_2\right\}>0$, then, if $|x-x_0|<\delta$, then:

$$\begin{aligned}\left|\frac{1}{f(x)}-\frac{1}{f\left(x_0\right)}\right| &= \frac{|f(x)-f\left(x_0\right)|}{|f(x)|\,|f\left(x_0\right)|}\\ &\leq \left(\frac{|f(x)-f\left(x_0\right)|}{|f\left(x_0\right)|}\right)\left(\frac{2}{|f\left(x_0\right)|}\right)\\ &= |f(x)-f\left(x_0\right)|\left(\frac{2}{|f\left(x_0\right)|^2}\right)\\ &< \left(\frac{\varepsilon|f\left(x_0\right)|^2}{2}\right)\left(\frac{2}{|f\left(x_0\right)|^2}\right)\\ &= \varepsilon\end{aligned} \tag{7.1.150}$$

And that finish the proof! If $f(x)$ is epsilon-delta continuous then we have indeed $\frac{1}{f}$ that is also epsilon-delta continuous at x_0.

P7. $f(x)/g(x)$ (also denoted $f/g(x)$) is also epsilon-delta continuous at x_0.

This is proven immediately using the property of epsilon-delta continuity of the inverse $(1/f(x))$ and of the multiplication $(f(x)\cdot 1/g(x))$.

P8. $f^n(x)$ is also epsilon-delta continuous at x_0.

This is immediate as it is product n times of $f\cdot f\cdot f\ldots$ as it follows from the property P4.

P9. $\sqrt[n]{x}$ is also epsilon-delta continuous at x_0.

The proof is given in the list of usual limits and continuities further below. What is much more useful is to prove the little bit more general case $\sqrt{f(x)}$ is epsilon-delta continuous!

Suppose you have to prove that $\sqrt{f(x)}$ is a continuous function (where $f(x)$ is continuous). We go by the definition of continuity. Take any $\varepsilon>0$. Then:

$$|\sqrt{f(x)}-\sqrt{f(y)}|^2=f(x)+f(y)-2\sqrt{f(x)f(y)} \tag{7.1.151}$$

Since $f(x)$ should be non-negative:

$$\begin{gathered}|\sqrt{f(x)}-\sqrt{f(y)}|^2<f(x)+f(y)=|f(x)+f(y)|\\ \Longrightarrow|\sqrt{f(x)}-\sqrt{f(y)}|<\sqrt{|f(x)+f(y)}\end{gathered} \tag{7.1.152}$$

Since $f(x)$ is continuous we know that there exist a $\delta>0$ such that:

$$|f(x)+f(y)|<\varepsilon^2 \text{ whenever } |x-y|<\delta \tag{7.1.153}$$

Hence:

$$|\sqrt{f(x)}-\sqrt{f(y)}|<\sqrt{|f(x)+f(y)}|<\varepsilon \text{ whenever } |x-y|<\delta \tag{7.1.154}$$

and therefore $\sqrt{f(x)}$ is epsilon-delta continuous!

P10. $g\circ f$ (also denoted $g(f(x))$ is also epsilon-delta continuous at x_0.

First a small reminder may be useful!:

If A,B,C are subsets of $\mathbb{R}$ and $f:A\rightarrow B$ and $g:B\rightarrow C$ are functions, then the composition $g\circ f:A\rightarrow C$ is defined by:

$$(g\circ f)(x)=g(f(x)) \tag{7.1.155}$$

Let's show that the composition of two epsilon-delta continuous functions is epsilon-delta continuous! In other words: If $f(x)$ is epsilon-delta continuous at x_0 and g is epsilon-delta continuous at $f(x_0)$, then $g\circ f$ is epsilon-delta continuous at x_0.

Let $\varepsilon>0$ be given.

Since g is epsilon-delta continuous at $f(x_0)$, there is $\delta'>0$ such that:

$$|x-f(x_0)|<\delta'\Rightarrow|g(x)-g(f(x_0))|<\varepsilon \tag{7.1.156}$$

Therefore there is $\delta'>0$ such that:

$$|f(x)-f(x_0)|<\delta'\Rightarrow|g(f(x))-g(f(x_0))|<\varepsilon \tag{7.1.157}$$

But now, since $f(x)$ is epsilon-delta continuous at x_0, by the definition of epsilon-delta continuity (but with δ' instead of ε), there is $\delta > 0$ such that if $|x-x_0|<\delta$, then $|f(x)-f(x_0)|<\delta'$.

Therefore, with δ as above, if $|x-x_0|<\delta$, then $|f(x)-f(x_0)|<\delta'$ and therefore:

$$|(g\circ f)(x)-(g\circ f)(x_0)| = |g(f(x))-g(f(x_0))| < \varepsilon \tag{7.1.158}$$

Therefore $g\circ f$ is epsilon-delta continuous at x_0.

7.1.2.1.1 Squeeze theorem

The "squeeze theorem" (also known as the "sandwich theorem", among other names[4]) is a theorem regarding the limit of a function that is trapped between two other functions.

The squeeze theorem is used in analysis, typically to confirm the limit of a function via comparison with two other functions whose limits are known. It was first used geometrically by the mathematicians Archimedes and Eudoxus in an effort to compute π, and was formulated in modern terms by Carl Friedrich Gauss. We will use it further below (in association with the definition of continuity) to compute/prove some very usual limits.

The squeeze theorem is formally stated as follow:

Theorem 7.3. Let I be an interval containing the point a. Let $g(x)$, $f(x)$, and $h(x)$ be functions defined on I, except possibly at a itself. Suppose that for every x in I not equal to a, we have:

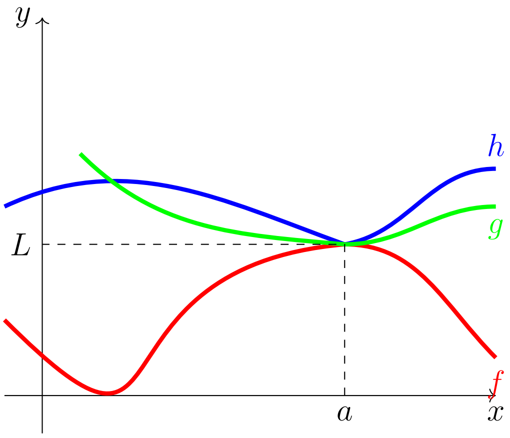
$$g(x)\leq f(x)\leq h(x) \tag{7.1.159}$$

and also suppose that:

$$\lim_{x\to a} g(x) = \lim_{x\to a} h(x) = L \tag{7.1.160}$$

Then:

$$\lim_{x\to a} f(x) = L \tag{7.1.161}$$



---

[4] Also known as the pinching theorem, the sandwich rule, the police theorem, the between theorem and sometimes the squeeze lemma. In Italy, the theorem is also known as the theorem of carabinieri.

The functions $g(x)$ and $h(x)$ are said to be lower and upper bounds (respectively) of $f(x)$ and converges to the limit a.

Here, a is not required to lie in the interior of I. Indeed, if a is an endpoint of I, then the above limits are left- or right-hand limits.

Remark

A similar statement holds for infinite intervals: for example, if $I=[0,+\infty[$, then the conclusion holds, taking the limits as $x\rightarrow+\infty$. This theorem is also valid for sequences. Let $(a_n),(c_n)$ be two sequences converging to ℓ, and (b_n) a sequence. If $\forall n\geq N, N\in\mathbb{N}$ we have $a_n\leq b_n\leq c_n$, then (b_n) also converges to ℓ.

According to the above hypotheses we have, taking the limit inferior and superior:

$$L=\lim_{x\rightarrow a} g(x)\leq\liminf_{x\rightarrow a} f(x)\leq\limsup_{x\rightarrow a} f(x)\leq\lim_{x\rightarrow a} h(x)=L \tag{7.1.162}$$

so all the inequalities are indeed equalities, and the thesis immediately follows.

Proof 7.3.1. A direct proof, using the (ε,δ)-definition of limit above, would be to prove that for all real $\varepsilon>0$ there exists a real $\delta>0$ such that for all x with $|x-a|<\delta$, we have $|f(x)-L|<\varepsilon$. Symbolically:

$$\forall\varepsilon>0,\exists\delta>0:\forall x,(|x-a|<\delta\Rightarrow|f(x)-L|<\varepsilon) \tag{7.1.163}$$

Let us assume that we know (because it is proven in the context of a special case) that:

$$\lim_{x\rightarrow a} g(x)=L \tag{7.1.164}$$

This means that:

$$\forall\varepsilon>0,\exists\delta_1>0:\forall x\,(|x-a|<\delta_1\Rightarrow|g(x)-L|<\varepsilon) \tag{7.1.165}$$

And let us also assume that we also know (because it is proven in the context of a special case) that:

$$\lim_{x\rightarrow a} h(x)=L \tag{7.1.166}$$

This means that:

$$\forall\varepsilon>0,\exists\delta_2>0:\forall x\,(|x-a|<\delta_2\Rightarrow|h(x)-L|<\varepsilon) \tag{7.1.167}$$

Then we have:

$$g(x)\leq f(x)\leq h(x) \tag{7.1.168}$$

and also:

$$g(x)-L\leq f(x)-L\leq h(x)-L \tag{7.1.169}$$

We can choose $\delta := \min\{\delta_1, \delta_2\}$. Then, if $|x-a| < \delta$, combining:

$$\begin{gathered}\forall \varepsilon > 0, \exists \delta_1 > 0 : \forall x\, (|x-a| < \delta_1 \Rightarrow |g(x) - L| < \varepsilon) \\ \text{and} \\ \forall \varepsilon > 0, \exists \delta_2 > 0 : \forall x\, (|x-a| < \delta_2 \Rightarrow |h(x) - L| < \varepsilon)\end{gathered} \tag{7.1.170}$$

We have:

$$-\varepsilon < g(x) - L \leq f(x) - L \leq h(x) - L < \varepsilon \tag{7.1.171}$$

Hence:

$$-\varepsilon < f(x) - L < \varepsilon \tag{7.1.172}$$

Which completes the proof!

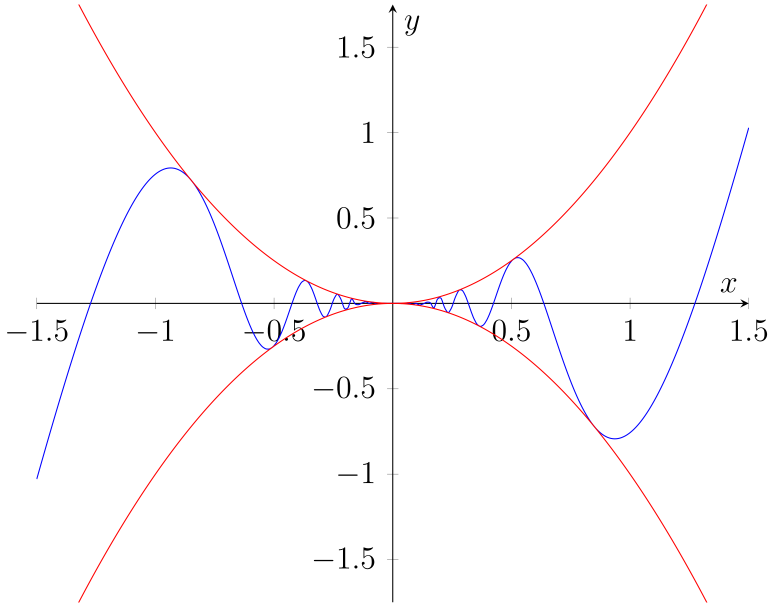
■ Q.E.D.

✍**Example:**

The limit:

$$\lim_{x \to 0} x^2 \sin\left(\frac{1}{x}\right)$$

illustrated below:



Cannot be determined through the limit law:

$$\lim_{x \to a} (f(x) \cdot g(x)) = \lim_{x \to a} f(x) \cdot \lim_{x \to a} g(x)$$

because:

$$\lim_{x \to 0} \sin\left(\frac{1}{x}\right)$$

does not exist.

However, by the definition of the sine function:

$$-1 \leq \sin\left(\frac{1}{x}\right) \leq 1$$

It follows that:

$$-x^2 \leq x^2 \sin\left(\frac{1}{x}\right) \leq x^2$$

Since (assuming that its continuity is proven somewhere):

$$\lim_{x\rightarrow 0} -x^2 = \lim_{x\rightarrow 0} x^2 = 0$$

by the squeeze theorem, $\lim_{x\rightarrow 0} x^2 \sin\left(\frac{1}{x}\right)$ must also be 0.

7.1.2.1.2 Usual Limits (and Continuities)

Delta-epsilon proofs are first found in the works of Augustin-Louis Cauchy (11789–11867 according to holocene calendar).

Here are some usual limits to know (obviously for each of them we will also prove if they are epsilon-delta continuous or not just for curiosity[5]):

1. For any real numbers a and c:

$$\lim_{x\rightarrow a} c = c \tag{7.1.173}$$

   - First we prove the epsilon-delta continuity:
     Let us apply the definition of epsilon-delta continuity. We pick an arbitrary real number x_0. Then for a given $\varepsilon > 0$, we are trying to find a $\delta > 0$ such that for all x:

$$|x - x_0| < \delta \Longrightarrow |f(x) - f(x_0)| = |k - k| = 0 < \varepsilon \tag{7.1.174}$$

     Since $0 < \varepsilon$ is true by hypothesis, we can choose an arbitrary δ like $\delta = \pi^{\pi^{\pi^{\pi}}}$. And this indeed satisfies the condition of epsilon-delta continuity at x_0.
     Since the choice for x_0 was arbitrary, this inequality holds for all real numbers and since the choice for k was arbitrary, this argument holds for all constant functions.
     Therefore, all constant functions are epsilon-delta continuous!
   - Second we prove the epsilon-delta limit:
     This is by definition. Don't need any proof.

2. For any real number a and $n \in \mathbb{N}^*$:

$$\lim_{x\rightarrow a} x^n = a^n \tag{7.1.175}$$

---

[5] Don't forget that the epsilon-delta continuity on a set or subset implies that the limit inside the same set or subset exist too but the contrary is not true!

- First we prove the epsilon-delta continuity:
  So we have to show $\forall\varepsilon>0$ there is a $\delta>0$ such that:

$$|x-x_0|<\delta \Longrightarrow |x^n-x_0^n|<\varepsilon \tag{7.1.176}$$

  We have to show that there is a δ that exists who satisfies the above relation.
  Let ε be any positive number. Denote $x_0+\delta=x$ and $x^n-x_0^n=\Delta$. Then identically:

$$\Delta=(x-x_0)\left(x^{n-1}+x^{n-2}x_0+\ldots+x_0^{n-1}\right) \tag{7.1.177}$$

  Taking the absolute value and using its triangle inequality (see section Arithmetics page 326) gives:

$$|\Delta|=|\delta|\cdot\left|x^{n-1}+x^{n-2}x_0+\ldots+x_0^{n-1}\right|\leq|\delta|\cdot\left(\left|x^{n-1}\right|+\left|x^{n-2}x_0\right|+\ldots+\left|x_0^{n-1}\right|\right) \tag{7.1.178}$$

  But since from the triangular inequality $|x|=|x_0+\delta|\leq|x_0|+|\delta|$ and also $|x_0|\leq|x_0|+|\delta|$, therefore each summand in the parentheses is at most equal to $(|x_0|+|\delta|)^{n-1}$, and since there are n summands, the sum is at most equal to $n\left(|x_0|+|\delta|\right)^{n-1}$. Thus we get:

$$|\Delta|\leqq n|\delta|\left(|x_0|+|h|\right)^{n-1} \tag{7.1.179}$$

  We may choose $|\delta|<1$. This implies:

$$|\Delta|\leq n|\delta|\left(|x_0|+1\right)^{n-1} \tag{7.1.180}$$

  The right hand side of this inequality is less than ε as soon as we still require:

$$|\delta|<\frac{\varepsilon}{n\left(|x_0|+1\right)^{n-1}} \tag{7.1.181}$$

  As we are able to find a δ means that the power function $x\mapsto x^n$ is epsilon-delta continuous at the point x_0 (however as the final relation depends on x_0 notice that it means the function is not uniform continuous!).
- Second we prove the epsilon-delta limit:
  The proof of the epsilon-delta limit is straightforward thanks to the previous result.
  As $x_0=a$, we have:

$$|\delta|<\frac{\varepsilon}{n\left(|a|+1\right)^{n-1}} \tag{7.1.182}$$

  And therefore we can always found a given ε such that the above inequality is satisfied and the limit exist on a. Then we can indeed write:

$$\lim_{x\to a}x^n=a^n \tag{7.1.183}$$

  Or here is another more detailed argument for those who prefer it:

$$\begin{aligned}&f(x)=x^n \text{ is continuous at } x_0>0\\&\Longleftrightarrow \lim_{x\to x_0}x^n=x_0^n\\&\Longleftrightarrow \forall\varepsilon>0,\exists\delta>0:\forall 0<|x-x_0|<\delta,|x^n-x_0^p|<\varepsilon\\&\Longleftrightarrow \forall\varepsilon>0,\exists\delta>0:\forall 0<\left|\frac{x}{x_0}-1\right|<\frac{\delta}{x_0},\left|\left(\frac{x}{x_0}\right)^n-1\right|<\frac{\varepsilon}{x_0^n}\end{aligned} \tag{7.1.184}$$

Let:

$$x'=\frac{x}{x_0},\delta'=\frac{\delta}{x_0},\varepsilon'=\frac{\varepsilon}{x_0^p}$$

Therefore:

$$\begin{aligned}&f(x)=x^n \text{ is continuous at } x_0>0\\ &\Longleftrightarrow \forall\varepsilon'>0,\exists\delta'>0:\forall 0<|x'-1|<\delta',|x'^n-1|<\varepsilon'\\ &\Longleftrightarrow \forall\varepsilon'>0,\exists\delta'>0:\forall 1-\delta<x'<1+\delta,x'\neq 1,1-\varepsilon'<x'^n<1+\varepsilon'\\ &\Longleftrightarrow \forall\varepsilon'>0,\exists\delta'>0:\forall 1-\delta'<x'<1+\delta',x'\neq 1,(1-\varepsilon')^{\frac{1}{n}}<x'<(1+\varepsilon')^{\frac{1}{n}}\end{aligned}\tag{7.1.185}$$

It is obvious to see that, we only need to put:

$$\delta=\min\left\{1-(1-\varepsilon')^{\frac{1}{n}},(1+\varepsilon')^{\frac{1}{n}}-1\right\}\tag{7.1.186}$$

in order the rightmost part of the final step to be satisfied. Therefore the epsilon-delta limit is proved to exist!

3. For any real number $a>0$:

$$\lim_{n\to+\infty}a^{1/n}=\lim_{n\to+\infty}\sqrt[n]{a}=1\tag{7.1.187}$$

- First we prove the epsilon-delta continuity:

  A function is epsilon-delta continuous at x_0 if, for any $\varepsilon>0$, there exists a $\delta>0$ so that, if $|x-x_0|<\delta$, then $|f(x)-f(x_0)|<\varepsilon$.

  Therefore:

$$\begin{aligned}|f(x)-f(x_0)|<\varepsilon\Leftrightarrow&\left|x^{1/n}-x_0^{1/n}\right|<\varepsilon\\ \Leftrightarrow& x_0^{1/n}-\varepsilon<x^{1/n}<x_0^{1/n}+\varepsilon\\ \Leftrightarrow&\left(x_0^{1/n}-\varepsilon\right)^n<x<\left(x_0^{1/n}+\varepsilon\right)^n\end{aligned}\tag{7.1.188}$$

  Thus, if we choose:

$$\delta=\min\left\{\left(c^{1/n}+\varepsilon\right)^n-c,c-\left(c^{1/n}-\varepsilon\right)^n\right\}\text{ for } c\neq 0\tag{7.1.189}$$

  then:

$$|x-x_0|<\delta\Rightarrow|f(x)-f(x_0)|<\varepsilon\tag{7.1.190}$$

  By the way that proves that if $f(x)>0$ is epsilon-delta continuous, then $\sqrt[n]{f(x)}$ is also epsilon-delta continuous!

  If you are not convinced of the last claim there is another way to show that! Further below we will prove in details that the exponential function e^x (see section Functional Analysis page 2289) and logarithm function $\log(x)$ are both epsilon-delta continuous. And as we can write:

$$\sqrt[n]{x}=e^{\ln(x)/n}\tag{7.1.191}$$

and we have proven earlier that if $f(x),g(x)$ are both epsilon-delta continuous then $g(f(x))$ is epsilon-delta continuous, then:

$$\sqrt[n]{x} \tag{7.1.192}$$

is epsilon-delta continuous too! And obviously we can replace x by a epsilon-delta continuous function $f(x)$ and the same reasoning would apply.

- Second we prove the epsilon-delta limit:
  Set $x_n=a^{1/n}$. We have:

$$\ln(x_n)=\frac{1}{n}\cdot\ln(a) \tag{7.1.193}$$

Clearly, we have:

$$\lim_{n\rightarrow+\infty}\ln(x_n)=0 \tag{7.1.194}$$

Hence:

$$\lim_{n\rightarrow+\infty}e^{\ln(x_n)}=e^0=1 \tag{7.1.195}$$

which translates into:

$$\lim_{n\rightarrow+\infty}a^{1/n}=1 \tag{7.1.196}$$

4. For any real numbers a and n:

$$\lim_{x\rightarrow a}\frac{x^n-a^n}{x-a}=na^{n-1} \tag{7.1.197}$$

- First we prove the epsilon-delta continuity:
  We have already proved earlier that if $f(x)$ is epsilon-delta continuous then $f^n(x)$ is epsilon-delta continuous and also that a^n is therefore also epsilon-delta continuous.
  We also have proven earlier that if $f(x),g(x)$ are epsilon-delta continuous then $f(x)-g(x)$ is also epsilon-delta continuous. Therefore we know that x^n-a^n and $x-a$ are epsilon-delta continuous.
  We also have proven earlier that if $f(x),g(x)$ are epsilon-delta continuous then $f(x)/g(x)$ is also epsilon-delta continuous if $g(x)\neq 0$. Therefore we know that:

$$\frac{x^n-a^n}{x-a} \tag{7.1.198}$$

is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:
  We simply use l'Hôpital's rule (see section Differential and Integral Calculus page 1461)! That is:

$$\lim_{x\rightarrow a}\frac{x^n-a^n}{x-a}=\lim_{x\rightarrow a}\frac{\dfrac{\mathrm{d}}{\mathrm{d}x}(x^n-a^n)}{\dfrac{\mathrm{d}}{\mathrm{d}x}(x-a)}=\lim_{x\rightarrow a}nx^{n-1}=na^{n-1} \tag{7.1.199}$$

5. For $a>0$ and n positive integer:

$$\lim_{x\to a}\frac{x-a}{x^n-a^n}=\frac{1}{na^{n-1}} \tag{7.1.200}$$

- First we prove the epsilon-delta continuity:

  The proof is straightforward as it is just the inverse of the previous example!

- Second we prove the epsilon-delta limit:

  It's just the inverse of the previous example so there is nothing special to prove!

6. We have:

$$\lim_{x\to 0}(1+x)^{1/x}=e \tag{7.1.201}$$

- First we prove the epsilon-delta continuity:

  We have already proved earlier that a constant is epsilon-delta continuous and x is also epsilon-delta continuous.

  We have also proved earlier that if $f(x),g(x)$ are epsilon-delta continuous then $f(x)+g(x)$ is epsilon-delta continuous and therefore $1+x$ is epsilon-delta continuous.

  We have also proved earlier that if $f(x)>0$ is epsilon-delta continuous that $f(x)^{1/x}$ is also epsilon-delta continuous. Therefore:

$$(1+x)^{1/x} \tag{7.1.202}$$

  is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

  This limit is already proven at page 2289.

7. For any real number a :

$$\lim_{x\to+\infty}\left(1+\frac{a}{x}\right)^x=e^a \tag{7.1.203}$$

This limit is well known by students in the special case where $a=1$.

- First we prove the epsilon-delta continuity:

  We have already proved earlier that a constant is epsilon-delta continuous. Therefore 1 is epsilon-delta continuous.

  We have also proved earlier that if $f(x),g(x)\neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is also epsilon-delta continuous and therefore a/x is epsilon-delta continuous.

  We have also proved earlier that if $f(x),g(x)$ are epsilon-delta continuous then $f(x)+g(x)$ is epsilon-delta continuous and therefore $1+(a/x)$ is epsilon-delta continuous.

  We have also proved earlier that if $f(x)$ is epsilon-delta continuous that $f(x)^n$ is also epsilon-delta continuous. Therefore:

$$\left(1+\frac{a}{x}\right)^x \tag{7.1.204}$$

  is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

  Let us note that it is equivalent to show that:

  $$\lim_{n\to+\infty}\frac{\ln\left(1+\frac{a}{n}\right)}{1/n}=a \tag{7.1.205}$$

  Do not worry about the domain of $\ln$, since for large n, the expression $1+\frac{a}{n}$ will be a positive number (close to 1). Consider the function:

  $$f(x)=\frac{\ln(1+x)}{x},\quad \text{for } x>0 \tag{7.1.206}$$

  and $f(0)=1$. Using the definition of the derivative of $\ln(1+x)$, we see that $f(x)$ is epsilon-delta continuous at 0, that is, $\lim_{x\to 0}f(x)=1=f(0)$. Hence, for any sequence $\{x_n\}$ which converges to 0, we have:

  $$\lim_{n\to+\infty}f(x_n)=f(0)=1 \tag{7.1.207}$$

  Now, set:

  $$x_n=\frac{a}{n} \tag{7.1.208}$$

  Clearly we have $x_n\to 0$. Therefore, we have:

  $$\lim_{n\to+\infty}\frac{\ln\left(1+\frac{a}{n}\right)}{\frac{a}{n}}=1 \tag{7.1.209}$$

  But, we have:

  $$\frac{\ln\left(1+\frac{a}{n}\right)}{\frac{1}{n}}=a\cdot\frac{\ln\left(1+\frac{a}{n}\right)}{\frac{a}{n}} \tag{7.1.210}$$

  which clearly implies:

  $$\lim_{n\to+\infty}\frac{\ln\left(1+\frac{a}{n}\right)}{1/n}=a \tag{7.1.211}$$

  Since:

  $$\left(1+\frac{a}{n}\right)^n=\exp\left(\frac{\ln\left(1+\frac{a}{n}\right)}{1/n}\right) \tag{7.1.212}$$

  we get:

  $$\lim_{n\to+\infty}\left(1+\frac{a}{n}\right)^n=e^a \tag{7.1.213}$$

8. We have:

$$\lim_{x\to 0}\frac{e^x-1}{x}=1 \tag{7.1.214}$$

- First we prove the epsilon-delta continuity:
  Suppose $|x-x_0|<\delta$ and fix $\varepsilon>0$.
  Consider $|e^x-e^{x_0}|<\varepsilon$, then using an engineer approach[6]:

$$\begin{gathered}-\varepsilon<e^x-e^{x_0}<\varepsilon\\ e^{x_0}-\varepsilon<e^x<e^{x_0}+\varepsilon\\ \ln\left(e^{x_0}-\varepsilon\right)<x<\ln\left(e^{x_0}+\varepsilon\right)\\ \ln\left(e^{x_0}-\varepsilon\right)-x_0<x-x_0<\ln\left(e^{x_0}+\varepsilon\right)-x_0\end{gathered}\tag{7.1.215}$$

  Hence e^x is epsilon-delta continuous at x_0 as long as:

$$\delta=\min\left\{x_0-\ln\left(e^{x_0}-\varepsilon\right),\ln\left(e^{x_0}+\varepsilon\right)-x_0\right\}\tag{7.1.216}$$

  Since x_0 is arbitrarily chosen then e^x is epsilon-delta continuous and we are done.

  Now that we have proven that the exponential is epsilon-delta continuous. We know that the numerator is epsilon-delta continuous and also that the denominator is epsilon-delta continuous. As we have proven earlier that if $f(x)$ and $g(x)$ are epsilon-delta continuous, then $f(x)/g(x)$ is epsilon-delta continuous too, this finish the proof!

- Second we prove the epsilon-delta limit:
  That latter is immediate using l'Hôpital's rule (see section Differential and Integral Calculus page 1461)! We have indeed:

$$\lim_{x\to 0}\frac{e^x-1}{x}=\lim_{x\to 0}\frac{\dfrac{\mathrm{d}}{\mathrm{d}x}(e^x-1)}{\dfrac{\mathrm{d}}{\mathrm{d}x}x}=\lim_{x\to 0}\frac{e^x}{1}=1\tag{7.1.217}$$

9. We have :

$$\lim_{x\to 0}\sin(x)=0\tag{7.1.218}$$

This limit must not be confused with the Maclaurin series that gives for small x that $\sin(x)\cong x$.

- First we prove the epsilon-delta continuity:
  Let $\varepsilon>0$ and $x,y\in\mathbb{R}$. We want:

$$|f(x)-f(y)|<\varepsilon\Longrightarrow|\sin(x)-\sin(y)|<\varepsilon\tag{7.1.219}$$

  Using trigonometric identities this is equivalent to:

$$\left|2\cos\left(\frac{x+y}{2}\right)\sin\left(\frac{x-y}{2}\right)\right|<\varepsilon\tag{7.1.220}$$

---

[6] Because for mathematicians this proof, although correct, relies on several facts about the logarithm, which (assuming it is defined as the inverse of the exponential) is usually shown to be a total function using the intermediate value theorem and hence assuming that the exponential is continuous... We also have to be careful with taking logs if $e^{x_0}-\varepsilon<0$...

Because $|\cos(\alpha)| \leqslant 1, \forall \alpha \in \mathbb{R}$ we can simplify:

$$\left|2\cos\left(\frac{x+y}{2}\right)\sin\left(\frac{x-y}{2}\right)\right| \leq 2\left|\sin\left(\frac{x-y}{2}\right)\right| \tag{7.1.221}$$

it suffices:

$$2\left|\sin\left(\frac{x-y}{2}\right)\right| < \varepsilon \tag{7.1.222}$$

when:

$$|x-y| < \delta \Longrightarrow \left|\frac{x-y}{2}\right| < \delta \tag{7.1.223}$$

Since $|\sin(x)| \leq |x|$:

$$2\left|\sin\left(\frac{x-y}{2}\right)\right| \leq 2\left|\frac{x-y}{2}\right| < 2\delta \tag{7.1.224}$$

Choosing $\delta = \varepsilon/2 > 0$ will do the trick. Because δ doesn't depend on x, y, the continuity is uniform!

- Second we prove the epsilon-delta limit:
  If we use the analytical definition of the $\sin(x)$ function (power series):

$$\sin(x) = \sum_{n=0}^{+\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!} \tag{7.1.225}$$

Therefore calculating:

$$\lim_{x\to 0} \sin(x) = 0 \tag{7.1.226}$$

is equivalent to:

$$\lim_{x\to 0} \sum_{n=0}^{+\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!} \tag{7.1.227}$$

And we have already proven earlier before that:

$$\lim_{x\to a} x^n = a^n \tag{7.1.228}$$

Therefore:

$$\lim_{x\to 0} \sum_{n=0}^{+\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!} = 0 \tag{7.1.229}$$

Hence:

$$\lim_{x\to 0} \sin(x) = 0 \tag{7.1.230}$$

10. We have:

$$\lim_{x\to 0}\cos(x)=1 \tag{7.1.231}$$

The method will be exactly similar to that of $\sin(x)$ seen just earlier!

- First we prove the epsilon-delta continuity:
  Let $\varepsilon>0$ and $x,y\in\mathbb{R}$. We want:

  $$|f(x)-f(y)|<\varepsilon \Longrightarrow |\cos(x)-\cos(y)|<\varepsilon \tag{7.1.232}$$

  Using trigonometric identities this is equivalent to:

  $$\left|2\sin\left(\frac{x+y}{2}\right)\sin\left(\frac{x-y}{2}\right)\right|<\varepsilon \tag{7.1.233}$$

  Because $|\sin(\alpha)|\leqslant 1,\forall\alpha\in\mathbb{R}$ we can simplify:

  $$\left|2\sin\left(\frac{x+y}{2}\right)\sin\left(\frac{x-y}{2}\right)\right|\leq 2\left|\sin\left(\frac{x-y}{2}\right)\right| \tag{7.1.234}$$

  it suffices:

  $$2\left|\sin\left(\frac{x-y}{2}\right)\right|<\varepsilon \tag{7.1.235}$$

  when:

  $$|x-y|<\delta \Longrightarrow \left|\frac{x-y}{2}\right|<\delta \tag{7.1.236}$$

  Since $|\sin(x)|\leq|x|$:

  $$2\left|\sin\left(\frac{x-y}{2}\right)\right|\leq 2\left|\frac{x-y}{2}\right|<2\delta \tag{7.1.237}$$

  Choosing $\delta=\varepsilon/2>0$ will do the trick. Because δ doesn't depend on x,y, the continuity is uniform.

- Second we prove the epsilon-delta limit:
  If we use the analytical definition of the $\cos(x)$ function (power series):

  $$\cos(x)=\sum_{n=0}^{+\infty}\frac{(-1)^n}{(2n)!}x^{2n} \tag{7.1.238}$$

  Therefore calculating:

  $$\lim_{x\to 0}\cos(x)=1 \tag{7.1.239}$$

  is equivalent to:

  $$\lim_{x\to 0}\sum_{n=0}^{+\infty}\frac{(-1)^n}{(2n)!}x^{2n}=\lim_{x\to 0}\left(1+\sum_{n=1}^{+\infty}\frac{(-1)^n}{(2n)!}x^{2n}\right) \tag{7.1.240}$$

And we have already proven earlier before that:

$$\lim_{x\to a} x^n = a^n \tag{7.1.241}$$

Therefore:

$$\lim_{x\to 0}\left(1+\sum_{n=1}^{+\infty}\frac{(-1)^n}{(2n)!}x^{2n}\right)=1+0=1 \tag{7.1.242}$$

Hence:

$$\lim_{x\to 0}\cos(x)=1 \tag{7.1.243}$$

11. We have:

$$\lim_{x\to 0}\tan(x)=0 \tag{7.1.244}$$

- First we prove the epsilon-delta continuity:
  The proof is straightforward! As by definition:

  $$\tan(x)=\frac{\sin(x)}{\cos(x)} \tag{7.1.245}$$

  He have proved earlier that $\sin(x)$ but also $\cos(x)$ are epsilon-delta continuous.
  But we have also proved that if $f(x),g(x)\neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is epsilon-delta continuous.
  Therefore $\tan(x)$ is epsilon-delta continuous!
- Second we prove the epsilon-delta limit:
  Notice that by the geometric definition we have:

  $$\lim_{x\to 0}\tan(x)=\lim_{x\to 0}\frac{\sin(x)}{\cos(x)}=\lim_{x\to 0}\sin(x)\lim_{x\to 0}\frac{1}{\cos(x)} \tag{7.1.246}$$

  And we have proved earlier above:

  $$\lim_{x\to 0}\sin(x)=0 \quad \text{and} \quad \lim_{x\to 0}\cos(x)=1 \tag{7.1.247}$$

  Therefore:

  $$\lim_{x\to 0}\tan(x)=\lim_{x\to 0}\sin(x)\lim_{x\to 0}\frac{1}{\cos(x)}=0 \tag{7.1.248}$$

12. We have:

$$\lim_{x\to 0}\frac{\sin(x)}{x}=1 \tag{7.1.249}$$

There are multiple ways more or less rigorous to prove that limit (geometric based, derivation based, series based, numerical based, squeeze theorem based, l'Hôpital theorem based, etc.) and that depend also on the definition of the function $\sin(x)$ itself...

- First we prove the epsilon-delta continuity:

  We have proven earlier that $\sin(x)$ is epsilon-delta continuous and also that x is epsilon-delta continuous. And we have proven earlier in the general case that if $f(x), g(x)$ are epsilon-delta continuous functions, assuming $g(x) \neq 0$, then $f(x)/g(x)$ is also epsilon-delta continuous!

  So that finish our proof!

- Second we prove the epsilon-delta limit:

  We have:

$$\lim_{x\to 0} \frac{\sin(x)}{x} = 1 \tag{7.1.250}$$

  if and only if for every $\varepsilon > 0$, there exists a $\delta > 0$ such that $|f(x) - 1| < \varepsilon$ whenever $0 < |x - 0| < \delta$.

  Let $\varepsilon > 0$ be an arbitrary real number.

  Note that:

$$\sin(x) = \sum_{n=0}^{+\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!} \tag{7.1.251}$$

  If $x \neq 0$, we have:

$$\frac{\sin(x)}{x} = \sum_{n=0}^{+\infty} (-1)^n \frac{x^{2n}}{(2n+1)!} = 1 + \sum_{n=1}^{+\infty} (-1)^n \frac{x^{2n}}{(2n+1)!} \tag{7.1.252}$$

  We thus have:

$$|f(x) - 1| = \left|\frac{\sin(x)}{x} - 1\right| = \left|\sum_{n=1}^{+\infty} (-1)^n \frac{x^{2n}}{(2n+1)!}\right| \leq \left|\sum_{n=1}^{+\infty} \frac{x^{2n}}{(2n+1)!}\right| \leq \sum_{n=1}^{+\infty} \left|\frac{x^{2n}}{(2n+1)!}\right| \tag{7.1.253}$$

  Therefore we have:

$$|f(x) - 1| \leq \sum_{n=1}^{+\infty} \left|\frac{x^{2n}}{(2n+1)!}\right| \leq \sum_{n=1}^{+\infty} \left|x^{2n}\right| = \sum_{n=1}^{+\infty} \left|x^2\right|^n \tag{7.1.254}$$

  If $0 < |x| < 1$, then $0 < |x^2| < 1$, and the infinite series $\sum_{n=1}^{+\infty} |x^2|^n$ converges to $\frac{x^2}{1-x^2}$. Choose $\delta := \sqrt{\frac{\varepsilon}{1+\varepsilon}}$. Then $0 < |x - 0| < \delta$ implies that $0 < |x| < \sqrt{\frac{\varepsilon}{1+\varepsilon}} < 1$, and hence $x^2 < \varepsilon - \varepsilon x^2$. But $x^2 < \varepsilon - \varepsilon x^2$ implies that $\frac{x^2}{1-x^2} < \varepsilon$.

  We therefore have $\sum_{n=1}^{+\infty} |x^2|^n < \varepsilon$ whenever $0 < |x - 0| < \delta$. But since $|f(x) - 1| \leq \sum_{n=1}^{+\infty} |x^2|^n$, we have $|f(x) - 1| < \varepsilon$ whenever $0 < |x - 0| < \delta$.

  Since ε was arbitrary, we have:

$$\lim_{x\to 0} \frac{\sin(x)}{x} = 1 \tag{7.1.255}$$

13. We have:

$$\lim_{x\to 0} \frac{\log(1+x)}{x} = 1 \tag{7.1.256}$$

- First we prove the epsilon-delta continuity:

  Let us put $z=1+x$ and we want to prove the epsilon-delta continuity near $x_0=0$ hence near $\log_b(1)$ for $b>1$.

  Let $\varepsilon>0$ and $z_0>0$. We want to find a small enough δ such that for $|z-z_0|<\delta$, $|\log_b(z)-\log_b(z_0)|<\varepsilon$. We have:

  $$|\log_b(z)-\log_b(z_0)|=\left|\log_b\left(\frac{z}{z_0}\right)\right| \tag{7.1.257}$$

  What we want is for z/z_0 to be close to 1. A better condition would be:

  $$b^{-\varepsilon}<\frac{z}{z_0}<b^{\varepsilon} \tag{7.1.258}$$

  In that case, we would have, by the strictly increasing nature of the $\log$ function:

  $$-\varepsilon<\log_b\left(\frac{z}{z_0}\right)<\varepsilon \tag{7.1.259}$$

  Therefore:

  $$\left|\log_b\left(\frac{z}{z_0}\right)\right|<|\varepsilon| \tag{7.1.260}$$

  So we are able to find such a ε but we see that the later is dependent of z_0 and we can't get rid of the latter. Hence $\log_b(z)$ is epsilon-delta continuous on z_0 but not uniformly continuous.

  Notice that in the literature it's very common to rearrange:

  $$b^{-\varepsilon}<\frac{z}{z_0}<b^{\varepsilon} \tag{7.1.261}$$

  as following:

  $$z_0b^{-\varepsilon}<z<z_0b^{\varepsilon} \tag{7.1.262}$$

  and to subtract z_0 everywhere such that:

  $$z_0b^{-\varepsilon}-z_0<z-z_0<z_0b^{\varepsilon}-z_0 \tag{7.1.263}$$

  As we wish to have $|z-z_0|<\delta$, he have finally:

  $$\delta=z_0\left\{1-b^{-\varepsilon},b^{-\varepsilon}-1\right\} \tag{7.1.264}$$

  When the base is the natural exponential the latter is written:

  $$\delta=z_0\left\{1-e^{-\varepsilon},e^{-\varepsilon}-1\right\} \tag{7.1.265}$$

- Second we prove the epsilon-delta limit:

  We simply use l'Hôpital's rule (see section Differential and Integral Calculus page 1461)! That is:

  $$\lim_{x\to 0}\frac{\log(1+x)}{x}=\lim_{x\to 0}\frac{\dfrac{\mathrm{d}}{\mathrm{d}x}\log(1+x)}{\dfrac{\mathrm{d}}{\mathrm{d}x}x}=\lim_{x\to 0}\frac{1}{1+x}=1 \tag{7.1.266}$$

14. We have:

$$\lim_{x\to 0}\frac{\sin^{-1}(x)}{x}=\frac{\arcsin(x)}{x}=1 \tag{7.1.267}$$

- First we prove the epsilon-delta continuity:

  Don't try to use the derivative or integral definition of $\arcsin(x)$ as they assume you already know that the function is epsilon-delta continuous! We want here to avoid using the "inverse theorem" as the latter is quite abstract and the proof not yet provided in this textbook (and very likely will never be!).

  The trick will be to used another expression for the $\arcsin(x)$ that uses the continuity proven earlier for $\sin(x)$. Let us remind for that purpose that we have proved in the section Numbers at page 252 the following de Moivre and Euler formula:

  $$\sin(x)=\frac{e^{\mathrm{i}x}-e^{-\mathrm{i}x}}{2\mathrm{i}} \tag{7.1.268}$$

  Let us put that as equal to y such that:

  $$y=\sin(x)=\frac{e^{\mathrm{i}x}-e^{-\mathrm{i}x}}{2\mathrm{i}} \tag{7.1.269}$$

  Hence:

  $$x=\arcsin(y) \tag{7.1.270}$$

  So we just need to solve for x. It will be a little bit easier if we do the substitution $e^{\mathrm{i}x}=z$. Therefore we get:

  $$2\mathrm{i}y=z-\frac{1}{z} \tag{7.1.271}$$

  And after rearranging:

  $$z^2-2\mathrm{i}yz-1=0 \tag{7.1.272}$$

  We apply the quadratic formula and get:

  $$z=\mathrm{i}y\pm\sqrt{1-y^2} \tag{7.1.273}$$

  One solution equals z the other solution equals $1/z$ pick one. And lets reverse the substitution:

  $$e^{\mathrm{i}x}=\mathrm{i}y+\sqrt{1-y^2} \tag{7.1.274}$$

  Therefore:

  $$x=-\mathrm{i}\ln\left(\mathrm{i}y+\sqrt{1-y^2}\right) \tag{7.1.275}$$

  So we have finally the interesting substitution:

  $$\arcsin(y)=-\mathrm{i}\ln\left(\mathrm{i}y+\sqrt{1-y^2}\right) \tag{7.1.276}$$

And we can rewrite our limit as:

$$\lim_{x\to 0}=\frac{\arcsin(x)}{x}=\frac{-\mathrm{i}\ln\left(\mathrm{i}x+\sqrt{1-x^2}\right)}{x}=1 \tag{7.1.277}$$

So we have to prove that:

$$\frac{\arcsin(x)}{x}=\frac{-\mathrm{i}\ln\left(\mathrm{i}x+\sqrt{1-x^2}\right)}{x} \tag{7.1.278}$$

is epsilon-delta continuous for $0<x<1$! And now that will be straightforward as we have proven that the sum of two epsilon-delta continuous function is epsilon-delta continuous (the content of the logarithm above). But also that the square root is epsilon-delta continuous (still the content of the logarithm above) and just previously that the logarithm is also epsilon-delta continuous! Hence the whole numerator above is epsilon-delta continuous for $0<x<1$!

And as the denominator (x) is also epsilon-delta continuous and that we have proven if $f(x),g(x)\neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is also epsilon-delta continuous. Then:

$$\frac{\arcsin(x)}{x}=\frac{-\mathrm{i}\ln\left(\mathrm{i}x+\sqrt{1-x^2}\right)}{x} \tag{7.1.279}$$

is indeed epsilon-delta continuous for $0<x<1$!

- Second we prove the epsilon-delta limit:

  We convert the inverse trigonometric sine function by the mathematical relationship between the trigonometric and inverse trigonometric functions. That is $y=\sin^{-1}(x)$, then $x=\sin(y)$.

  Therefore, the quotient of $\arcsin(x)$ by x can be written as the ratio of y to $\sin(y)$ mathematically:

$$\frac{\sin^{-1}(x)}{x}=\frac{y}{\sin(y)} \tag{7.1.280}$$

  Therefore, if x approaches zero, then y tends to $\sin^{-1}(0)$. More explicitly:

$$\lim_{x\to 0}\frac{\arcsin(x)}{x}=\lim_{y\to 0}\frac{y}{\sin(y)}=\lim_{y\to 0}\frac{1}{\frac{\sin(y)}{y}}=\frac{1}{1}=1 \tag{7.1.281}$$

15. We have:

$$\lim_{x\to 0}\frac{\tan(x)}{x}=1 \tag{7.1.282}$$

- First we prove the epsilon-delta continuity:

  We have already proved earlier that $\tan(x)$ is epsilon-delta continuous and same for x.

  We have also proved earlier that if $f(x),g(x)\neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is also epsilon-delta continuous.

  Therefore:

$$\frac{\tan(x)}{x} \tag{7.1.283}$$

  is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

  Once we have proved:

$$\lim_{x\to 0}\frac{\sin(x)}{x}=1 \quad \text{and} \quad \lim_{x\to 0}\cos(x)=1 \tag{7.1.284}$$

  We can prove quite easily that:

$$\lim_{x\to 0}\frac{\tan(x)}{x}=1 \tag{7.1.285}$$

  Indeed:

$$\lim_{x\to 0}\frac{\tan(x)}{x}=\lim_{x\to 0}\frac{\sin(x)}{x\cdot\cos(x)}=\lim_{x\to 0}\frac{\sin(x)}{x}\lim_{x\to 0}\frac{1}{\cos(x)}=1\cdot 1=1 \tag{7.1.286}$$

16. We have:

$$\lim_{x\to 0}\frac{\tan^{-1}(x)}{x}=\frac{\arctan(x)}{x}=1 \tag{7.1.287}$$

- First we prove the epsilon-delta continuity:

  Don't try to use the derivative or integral definition of $\arctan(x)$ as they assume you already know that the function is epsilon-delta continuous! We want here to avoid using the "inverse theorem" as the latter is quite abstract and the proof not yet provided in this textbook (and very likely will never be!).

  The trick will be to used another expression for the $\arctan(x)$ that uses the continuity proven earlier for $\sin(x)$ and $\cos(x)$. Let us remind for that purpose that we have proved in the section Numbers at page 252 the following de Moivre and Euler formula:

$$\sin(\varphi)=\frac{e^{\mathrm{i}\varphi}-e^{-\mathrm{i}\varphi}}{2\mathrm{i}},\quad \cos(\varphi)=\frac{e^{\mathrm{i}\varphi}+e^{-\mathrm{i}\varphi}}{2} \tag{7.1.288}$$

  which leads to:

$$\tan(\varphi)=\frac{\sin(\varphi)}{\cos(\varphi)}=\frac{e^{\mathrm{i}\varphi}-e^{-\mathrm{i}\varphi}}{\mathrm{i}\left(e^{\mathrm{i}\varphi}+e^{-\mathrm{i}\varphi}\right)} \tag{7.1.289}$$

  Let $\tan(\varphi)=x$, then:

$$\frac{e^{\mathrm{i}\varphi}-e^{-\mathrm{i}\varphi}}{e^{\mathrm{i}\varphi}+e^{-\mathrm{i}\varphi}}=\mathrm{i}x \tag{7.1.290}$$

  and solving it we find that:

$$e^{\mathrm{i}\varphi}=\sqrt{\frac{1+\mathrm{i}x}{1-\mathrm{i}x}} \tag{7.1.291}$$

  which leads us to:

$$\arctan(x)=\varphi=\frac{1}{\mathrm{i}}\ln\sqrt{\frac{1+\mathrm{i}x}{1-\mathrm{i}x}}=\frac{\mathrm{i}}{2}[\ln(1-\mathrm{i}x)-\ln(1+\mathrm{i}x)] \tag{7.1.292}$$

  when $\forall x\in\mathbb{C}\backslash(\mathrm{i}(]-\infty,-1]\cup[1,+\infty[))$.

Therefore we can rewrite the limit above as:

$$\lim_{x\to 0}\frac{\tan^{-1}(x)}{x}=\frac{\arctan(x)}{x}=\frac{\frac{\mathrm{i}}{2}[\ln(1-\mathrm{i}x)-\ln(1+\mathrm{i}x)]}{x}=1 \tag{7.1.293}$$

As we have proven that a constant is epsilon-delta continuous and x (and therefore $\mathrm{i}x$) is also epsilon-delta continuous then $1-\mathrm{i}x$ and $1+\mathrm{i}x$ are both epsilon-delta continuous.

But we have also proved earlier above that the logarithm is epsilon-delta continuous. Therefore as we have proven that if $f(x),g(x)$ are epsilon-delta continuous then $g(f(x))$ is also epsilon-delta continuous that lead us to the result that $\ln(1-\mathrm{i}x)$ and $\ln(1+\mathrm{i}x)$ are both epsilon-delta continuous!

As we have also proved that if $f(x),g(x)\neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is also epsilon-delta continuous then the ratio of of $\ln(1-\mathrm{i}x)-\ln(1+\mathrm{i}x)$ by x is also epsilon-delta continuous.

Finally we have proven that:

$$\frac{\tan^{-1}(x)}{x}=\frac{\arctan(x)}{x}=\frac{\frac{\mathrm{i}}{2}[\ln(1-\mathrm{i}x)-\ln(1+\mathrm{i}x)]}{x} \tag{7.1.294}$$

is indeed epsilon-delta continuous $\forall x\in\mathbb{C}\backslash(\mathrm{i}(]-\infty,-1]\cup[1,+\infty[))$.

- Second we prove the epsilon-delta limit:

  This is straightforward. Again we just use l'Hospital rule (see section Differential and Integral Calculus page 1461) and this leads to:

$$\lim_{x\to 0}\frac{\arctan(x)}{x}=\lim_{x\to 0}\frac{\frac{\mathrm{d}}{\mathrm{d}t}\arctan(x)}{\frac{\mathrm{d}}{\mathrm{d}t}x}=\lim_{x\to 0}\frac{\frac{1}{1+x^2}}{1}=\lim_{x\to 0}\frac{1}{1+x^2}=1 \tag{7.1.295}$$

17. We have:

$$\lim_{x\to 0}\frac{a^x-1}{x}=\ln(a) \tag{7.1.296}$$

- First we prove the epsilon-delta continuity:

  This is straightforward to prove! We have proven earlier that a constant (like 1) is epsilon-delta continuous.

  We have also proven that x is epsilon-delta continuous.

  We have proven that if $f(x),g(x)$ are epsilon-delta continuous then $f(x)+g(x)$ and $f(x)-g(x)$ are also epsilon-delta continuous.

  We have proven earlier that if $f(x)$ is epsilon-delta continuous then $f(x)^n$ is epsilon-delta continuous. Therefore a^x-1 is epsilon-delta continuous.

  We have proven that if $f(x),g(x)\neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is also epsilon-delta continuous.

  Therefore:

$$\frac{a^x-1}{x}=\ln(a) \tag{7.1.297}$$

is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

  $$\lim_{x\to 0}\frac{a^x-1}{x} \tag{7.1.298}$$

  Let $y=a^x-1$, then $1+y=a^x$.
  Consider the relation:

  $$1+y=a^x \tag{7.1.299}$$

  Using the logarithm on both sides, we have:

  $$\begin{aligned}&\ln(1+y)=\ln(a^x)\\ \Rightarrow&\ln(1+y)=x\ln(a)\\ \Rightarrow&x=\frac{\ln(1+y)}{\ln(a)}\end{aligned} \tag{7.1.300}$$

  Also:

  $$\lim_{x\to 0} y=\lim_{x\to 0}(a^x-1)=a^0-1=1-1=0 \tag{7.1.301}$$

  This shows that $y\to 0$ as $x\to 0$. Therefore, the given limit can be written as:

  $$\begin{aligned}&\lim_{x\to 0}\frac{a^x-1}{x}=\lim_{y\to 0}\frac{y}{\frac{\ln(1+y)}{\ln(a)}}\\ \Rightarrow&\lim_{x\to 0}\frac{a^x-1}{x}=\lim_{y\to 0}\frac{\ln(a)}{\frac{1}{y}\ln(1+y)}\\ \Rightarrow&\lim_{x\to 0}\frac{a^x-1}{x}=\lim_{y\to 0}\frac{\ln a}{\ln(1+y)^{\frac{1}{y}}}\\ \Rightarrow&\lim_{x\to 0}\frac{a^x-1}{x}=\frac{\ln(a)}{\lim_{y\to 0}\ln(1+y)^{\frac{1}{y}}}\\ \Rightarrow&\lim_{x\to 0}\frac{a^x-1}{x}=\frac{\ln(a)}{\ln\left[\lim_{y\to 0}(1+y)^{\frac{1}{y}}\right]}\end{aligned} \tag{7.1.302}$$

  Using the relation $\lim_{x\to 0}(1+x)^{\frac{1}{x}}=e$, we have:

  $$\Rightarrow\lim_{x\to 0}\frac{a^x-1}{x}=\frac{\ln(a)}{\ln(e)} \tag{7.1.303}$$

  But $\ln(e)=1$, we have:

  $$\Rightarrow\lim_{x\to 0}\frac{a^x-1}{x}=\frac{\ln(a)}{1}=\ln(a) \tag{7.1.304}$$

18. We have:

$$\lim_{x\to 0}\frac{(1+x)^m-1}{x}=m \tag{7.1.305}$$

- First we prove the epsilon-delta continuity:

  This is straightforward to prove! We have proven earlier that a constant (like 1) is epsilon-delta continuous.

  We have also proven that x is epsilon-delta continuous.

  We have proven that if $f(x), g(x)$ are epsilon-delta continuous then $f(x)+g(x)$ and $f(x)-g(x)$ are also epsilon-delta continuous. Therefore $1+x$ is epsilon-delta continuous.

  We have proven earlier that if $f(x)$ is epsilon-delta continuous then $f(x)^n$ is epsilon-delta continuous. Therefore $(1+x)^m-1$ is epsilon-delta continuous.

  We have proven that if $f(x), g(x) \neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is also epsilon-delta continuous. Therefore:

  $$\frac{(1+x)^m-1}{x} \tag{7.1.306}$$

  is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

  This is straightforward. Again we just use l'Hospital rule (see section Differential and Integral Calculus page 1461) and this leads to:

  $$\lim_{x\rightarrow 0}\frac{(1+x)^m-1}{x}=\lim_{x\rightarrow 0}\frac{\dfrac{\mathrm{d}}{\mathrm{d}t}(1+x)^m-1}{\dfrac{\mathrm{d}}{\mathrm{d}t}x}=\lim_{x\rightarrow 0}\frac{m(x+1)}{1}=\lim_{x\rightarrow 0}m(x+1)=m \tag{7.1.307}$$

19. We have:

$$\lim_{x\rightarrow 0}\frac{1-\cos(x)}{x}=0 \tag{7.1.308}$$

- First we prove the epsilon-delta continuity:

  The proof is straightforward! We have already proved earlier that a constant is epsilon-delta continuous therefore 1 has the same behaviour.

  We have already proved also earlier that $\cos(x)$ is epsilon-delta continuous !

  And we have proved that x is epsilon-delta continuous.

  We have proved that if $f(x), g(x)$ are epsilon-delta continuous then $f(x)-g(x)$ is epsilon-delta continuous. Therefore $1-\cos(x)$ is epsilon-delta continuous.

  We have proved that if $f(x), g(x) \neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is epsilon-delta continuous. Therefore:

  $$\frac{1-\cos(x)}{x} \tag{7.1.309}$$

  is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

$$\begin{aligned}\lim_{x\to 0}\frac{1-\cos(x)}{x}&=\lim_{x\to 0}\frac{(1-\cos(x))(1+\cos(x))}{x(1+\cos(x))}=\lim_{x\to 0}\frac{1-\cos(x)+\cos(x)-\cos^2(x)}{x(1+\cos(x))}\\&=\lim_{x\to 0}\frac{1-\cos^2(x)}{x(1+\cos(x))}=\lim_{x\to 0}\frac{\sin^2(x)}{x(1+\cos(x))}=\lim_{x\to 0}\frac{\sin(x)}{x}\cdot\frac{\sin(x)}{1+\cos(x)}\\&=\left(\lim_{x\to 0}\frac{\sin(x)}{x}\right)\left(\lim_{x\to 0}\frac{\sin(x)}{1+\cos(x)}\right)\end{aligned}\tag{7.1.310}$$

  We have proven earlier above that:

$$\lim_{x\to 0}\frac{\sin(x)}{x}=1\tag{7.1.311}$$

  Hence:

$$\begin{aligned}\lim_{x\to 0}\frac{1-\cos(x)}{x}&=\lim_{x\to 0}\frac{(1-\cos(x))(1+\cos(x))}{x(1+\cos(x))}=\left(\lim_{x\to 0}\frac{\sin(x)}{x}\right)\left(\lim_{x\to 0}\frac{\sin(x)}{1+\cos(x)}\right)\\&=1\cdot\lim_{x\to 0}\frac{\sin(x)}{1+\cos(x)}\\&=\frac{\sin(0)}{1+\cos(0)}=\frac{0}{1+1}=0\end{aligned}\tag{7.1.312}$$

20. We have:

$$\lim_{x\to+\infty}x^{1/x}=1\tag{7.1.313}$$

often denoted:

$$\lim_{n\to+\infty}n^{1/n}=1\tag{7.1.314}$$

- First we prove the epsilon-delta continuity:
  The proof is straightforward as:

$$f(x)=x^{\frac{1}{x}}=e^{\frac{1}{x}\ln(x)}\tag{7.1.315}$$

  Indeed, we have proven in the previous examples that for $x>0$, we had $1/x$ and $\ln(x)$ were epsilon-delta continuous.
  And as we have proven in the general case that if $f(x),g(x)$ are epsilon-delta continuous then $f(x)\cdot g(x)$ was also epsilon-delta continuous, then $\frac{1}{x}\ln(x)$ is epsilon-delta continuous!
  We have also proven in the example above that the exponential e is epsilon-delta continuous. And because we have proven in the general case that if $f(x),g(x)$ are epsilon-delta continuous then $g(f(x))$ is also epsilon-delta continuous, then:

$$e^{\frac{1}{x}\ln(x)}\tag{7.1.316}$$

  is epsilon-delta continuous and so is $x^{1/x}$!

- Second we prove the epsilon-delta limit:
  Set $x_n = n^{1/n}$. We have:

$$\ln\left(x_n\right) = \frac{\ln(n)}{n} \qquad (7.1.317)$$

  Clearly, we have (from above):

$$\lim_{n\to+\infty} \ln\left(x_n\right) = 0 \qquad (7.1.318)$$

  Hence:

$$\lim_{n\to+\infty} e^{\ln(x_n)} = e^0 = 1 \qquad (7.1.319)$$

  which translates into:

$$\lim_{n\to+\infty} n^{1/n} = 1 \qquad (7.1.320)$$

21. We have:

$$\lim_{x\to0^+} x\ln(x) = 0 \qquad (7.1.321)$$

- First we prove the epsilon-delta continuity:
  The proof is straightforward as we have proven that $\log(x)$ is epsilon-delta continuous (therefore $\ln(x)$ has the same behaviour) and that x is also epsilon-delta continuous.
  And we have proved earlier that if $f(x), g(x)$ are epsilon-delta continuous then $f(x)\cdot g(x)$ is also epsilon-delta continuous.
  Hence:

$$x\ln(x) \qquad (7.1.322)$$

  is epsilon-delta continuous!
- Second we prove the epsilon-delta limit:
  If we evaluate the limit of the numerator and denominator separately we'll find that as $\ln(x)$ goes to $+\infty$ as x goes to $+\infty : \ln(+\infty) = +\infty$ and x goes to $+\infty$.
  Therefore we have a ratio of two infinities $\frac{+\infty}{+\infty}$ meaning that we will have to apply l'Hôpital's rule (see section Differential and Integral Calculus page 1461):

$$\lim_{x\to+\infty} \frac{\ln(x)}{x} = \lim_{x\to+\infty} \frac{\frac{\mathrm{d}}{\mathrm{d}x}(\ln(x))}{\frac{\mathrm{d}}{\mathrm{d}x}(x)} = \lim_{x\to+\infty} \frac{\frac{1}{x}}{1} = \lim_{x\to+\infty} \frac{1}{x} = 0 \qquad (7.1.323)$$

  The limit approaches 0 because 1 divided over something approaching $+\infty$ becomes closer and closer to 0.

22. We have:

$$\lim_{x\to+\infty} \frac{\ln(x)}{x} = 0 \qquad (7.1.324)$$

- First we prove the epsilon-delta continuity:

  We have already proved earlier that $\log(x)$ is epsilon-delta continuous.

  We have also already proved earlier that x is epsilon-delta continuous.

  We have proved earlier that if we have $f(x), g(x) \neq 0$ that are epsilon-delta continuous then $f(x)/g(x)$ is epsilon-delta continuous.

  Therefore:

  $$\frac{\ln(x)}{x} \tag{7.1.325}$$

  is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

  The proof is straightforward using l'Hôpital's rule (see section Differential and Integral Calculus page 1461)! Indeed:

  $$\lim_{x\to+\infty}\frac{\ln(x)}{x}=\lim_{x\to+\infty}\frac{\dfrac{\mathrm{d}}{\mathrm{dx}}\ln(x)}{\dfrac{\mathrm{d}}{\mathrm{dx}}x}=\lim_{x\to+\infty}\frac{1}{x}=0 \tag{7.1.326}$$

23. We have:

$$\lim_{x\to 0} x^x=1 \tag{7.1.327}$$

- First we prove the epsilon-delta continuity:

  The proof follows exactly the same pattern as the case with $x^{1/x}$ done earlier above and leads to the same conclusion: x^x is epsilon-delta continuous for $x>0$.

- Second we prove the epsilon-delta limit:

  The proof uses a result we have obtained in one of the previous example. That is:

  $$\lim_{x\to 0} x\ln(x)=0 \tag{7.1.328}$$

  How? That's easy! We just rewrite:

  $$\lim_{x\to 0} x^x=e^{x\ln(x)} \tag{7.1.329}$$

  And therefore the result is immediate:

  $$\lim_{x\to 0} x^x=e^{x\ln(x)}=e^0=1 \tag{7.1.330}$$

24. We have:

$$\lim_{x\to 0}(1+\sin(x))^{1/x}=e \tag{7.1.331}$$

- First we prove the epsilon-delta continuity:

  That will be also straightforward thank to all previous examples!

  First we have proven that a constant like 1 is epsilon-delta continuous.

  We have also proven that $\sin(x)$ is epsilon-delta continuous.

We have also proven that in the general case if $f(x), g(x)$ are epsilon-delta continuous then $f(x)+g(x)$ is epsilon-delta continuous. Therefore $1+\sin(x)$ is epsilon-delta continuous.

We have proven earlier that if $x>0$ then $x^{1/x}$ was epsilon-delta continuous. Therefore we conclude (in the engineering way...) that:

$$(1+\sin(x))^{1/x} \tag{7.1.332}$$

is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

  Here we use exactly the same trick as before...! That is we rewrite the limit as:

  $$\lim_{x\to 0} e^{\frac{1+\sin(x)}{x}} \tag{7.1.333}$$

  Therefore we just have to compute:

  $$\lim_{x\to 0} \frac{1+\sin(x)}{x} \tag{7.1.334}$$

  We use l'Hôpital's rule (see section Differential and Integral Calculus page 1461)! Therefore we get:

  $$\lim_{x\to 0} \frac{1+\sin(x)}{x} = \frac{\dfrac{\mathrm{d}}{\mathrm{d}x}(1+\sin(x))}{\dfrac{\mathrm{d}}{\mathrm{d}x}x} = \lim_{x\to 0} \cos(x) = 1 \tag{7.1.335}$$

  Therefore:

  $$\lim_{x\to 0}(1+\sin(x))^{1/x} = \lim_{x\to 0} e^{\frac{1+\sin(x)}{x}} = e^1 = e \tag{7.1.336}$$

25. We have for any real a:

$$\lim_{x\to +\infty} x-\sqrt{x^2-a^2} = 0 \tag{7.1.337}$$

- First we prove the epsilon-delta continuity:

  The proof is straightforward using again the results of the previous examples and the general properties of epsilon-delta continuity!

  Indeed, we have already proven that a constant (like a or like a^2 that is still a constant too) is epsilon-delta continuous.

  We have also proven earlier above that x^2 is epsilon-delta continuous.

  And as we have proven the property that if $f(x), g(x)$ are epsilon-delta continuous then $f(x)-g(x)$ is epsilon-delta continuous. That means x^2-a^2 is epsilon-delta continuous.

  We have proven earlier also that if $f(x)>0$ is epsilon-delta continuous then $\sqrt{f(x)}$ is also epsilon-delta continuous. Therefore for $x^2-a^2>0$ (i.e. $x^2>a^2$, or $|x|>|a|$), we have that $\sqrt{x^2-a^2}$ is epsilon-delta continuous too!

- Second we prove the epsilon-delta limit:
  We use a trick:

  $$\lim_{x\rightarrow+\infty} x-\sqrt{x^2-a^2}=\lim_{x\rightarrow+\infty}\left(x-\sqrt{x^2-a^2}\right)\frac{x+\sqrt{x^2-a^2}}{x+\sqrt{x^2-a^2}} \tag{7.1.338}$$

  Hence after simplification:

  $$\lim_{x\rightarrow+\infty}\frac{a^2}{x+\sqrt{x^2-a^2}}=a^2\lim_{x\rightarrow+\infty}\frac{1}{x+\sqrt{x^2-a^2}} \tag{7.1.339}$$

  It's obvious now as $x>a$ and therefore that $\sqrt{x^2-a^2}\geq 0$ that:

  $$\lim_{x\rightarrow+\infty} x+\sqrt{x^2-a^2}=+\infty \tag{7.1.340}$$

  Hence:

  $$\lim_{x\rightarrow+\infty} x-\sqrt{x^2-a^2}=a^2\lim_{x\rightarrow+\infty}\frac{1}{x+\sqrt{x^2-a^2}}=\frac{1}{+\infty}=0 \tag{7.1.341}$$

26. We have:

  $$\lim_{x\rightarrow 0}\frac{\tan(x)-\sin(x)}{x^3}=\frac{1}{2} \tag{7.1.342}$$

  - First we prove the epsilon-delta continuity:
    This is quite straightforward thanks to everything we have proven so far! Indeed, we have proven earlier above that $\tan(x)$ and $\sin(x)$ are epsilon-delta continuous. But we have also proven earlier that if $f(x),g(x)$ are epsilon-delta continuous then $f(x)-g(x)$ is epsilon-delta continuous. Therefore $\tan(x)-\sin(x)$ is epsilon-delta continuous.
    And we have also proven earlier that if $f(x)$ is epsilon-delta continuous then $f(x)^n$ is also epsilon-delta continuous and therefore x^3 at the denominator is also epsilon-delta continuous.
    And finally as we have proven earlier that if $f(x),g(x)\neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is also epsilon-delta continuous and therefore:

    $$\frac{\tan(x)-\sin(x)}{x^3} \tag{7.1.343}$$

    is epsilon-delta continuous!
  - Second we prove the epsilon-delta limit:
    Let us do that without l'Hôpital's rule (personal choice!). So we use the definitions of trigonometric functions:

    $$\begin{aligned}\frac{\tan(x)-\sin(x)}{x^3}&=\frac{\dfrac{\sin(x)}{\cos(x)}-\sin(x)}{x^3}=\frac{\left(\dfrac{\sin(x)-\sin(x)\cos(x)}{\cos(x)}\right)}{x^3}\\&=\frac{\sin(x)-\sin(x)\cos(x)}{x^3\cos(x)}=\frac{\sin(x)(1-\cos(x))}{x^3\cos(x)}=\frac{\sin(x)}{x}\cdot\frac{1-\cos(x)}{x^2\cos(x)}\\&=\frac{\sin(x)}{x}\frac{1-\cos(x)}{x^2\cos(x)}\frac{(1+\cos(x))}{(1+\cos(x))}=\frac{\sin(x)}{x}\frac{1-\cos^2(x)}{x^2\cos(x)(1+\cos(x))}\\&=\frac{\sin(x)}{x}\frac{\sin^2(x)}{x^2\cos(x)(1+\cos(x))}=\frac{\sin(x)}{x}\left(\frac{\sin(x)}{x}\right)^2\frac{1}{\cos(x)(1+\cos(x))}\end{aligned} \tag{7.1.344}$$

Using the property that:

$$\lim_{x\rightarrow 0} f(x)g(x)=\lim_{x\rightarrow 0} f(x)\cdot\lim_{x\rightarrow 0} g(x) \tag{7.1.345}$$

We get:

$$\begin{aligned}\lim_{x\rightarrow 0}\frac{\tan(x)-\sin(x)}{x^3}&=\lim_{x\rightarrow 0}\frac{\sin(x)}{x}\cdot\left(\lim_{x\rightarrow 0}\frac{\sin(x)}{x}\right)^2\cdot\lim_{x\rightarrow 0}\frac{1}{\cos(x)(1+\cos(x))}\\&=1\cdot 1^2\cdot\frac{1}{1\cdot(1+1)}=\frac{1}{2}\end{aligned} \tag{7.1.346}$$

27. For $q>0$:

$$\lim_{x\rightarrow+\infty}\frac{\log^p(x)}{x^q}=0 \tag{7.1.347}$$

- First we prove the epsilon-delta continuity:

  The proof will be straightforward again thanks to everything we have proven so far! Indeed, we have proven earlier that the logarithm is epsilon-delta continuous, therefore $\log(x)$ is epsilon-delta continuous.

  We have also proven that x is epsilon-delta continuous.

  We have also proven that if $f(x)$ is an epsilon-delta continuous function then $f^n(x)$ is also epsilon-delta continuous. Hence $\log^p(x)$ and x^q are epsilon-delta continuous.

  And finally as we have proven that if $f(x),g(x)\neq 0$ are epsilon-delta continuous then $f(x)/g(x)$ is epsilon-delta continuous that lead us to the conclusion that:

  $$\frac{\log^p(x)}{x^q} \tag{7.1.348}$$

  is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

  We simply use l'Hôpital's rule (see section Differential and Integral Calculus page 1461)! That is:

  $$\lim_{x\rightarrow+\infty}\frac{\log^p(x)}{x^q}=\frac{\dfrac{\mathrm{d}}{\mathrm{d}x}\log^p(x)}{\dfrac{\mathrm{d}}{\mathrm{d}x}x^q}=\lim_{x\rightarrow+\infty}\frac{1/x}{qx^{q-1}}=\lim_{x\rightarrow+\infty}\frac{1}{qx^q}=0 \tag{7.1.349}$$

28. We have:

$$\lim_{x\rightarrow+\infty} n(\sqrt[n]{x}-1)=\log(x) \tag{7.1.350}$$

This formula is due to the English scientist and mathematician Edmond Halley (11656 to 11742 according to holocene calendar) and was known also by Leonhard Euler, who used it for defining the natural logarithm.

- First we prove the epsilon-delta continuity:

  The proof is straightforward we everything we have seen so far! Indeed, in the first examples above we have proven that $\sqrt[n]{x}$ is epsilon-delta continuous and also that a constant (like 1) is also epsilon-delta continuous.

  But we have proven earlier that if $f(x),g(x)$ are the both epsilon-delta continuous then $f(x)-g(x)$ is also epsilon-delta continuous. Therefore $\sqrt[n]{x}-1$ is epsilon-delta continuous.

  And finally we have proven that if $f(x)$ is epsilon-delta continuous then that same function multiplied by a constant is also epsilon-delta continuous. Therefore:

  $$n(\sqrt[n]{x}-1) \tag{7.1.351}$$

  is epsilon-delta continuous!

- Second we prove the epsilon-delta limit:

  We change the n-th root to power of e and use the power series expansion of exponential function:

  $$\begin{aligned}n(\sqrt[n]{x}-1)&=n\left(e^{\frac{\ln(x)}{n}}-1\right)=n\left(\sum_{m=0}^{+\infty}\frac{(\ln(x)/n)^m)}{m!}-1\right)\\&=\sum_{m=1}^{+\infty}\frac{n(\ln(x)/n)^m}{m!}=\ln(x)+\frac{1}{n}\sum_{m=2}^{+\infty}\frac{(\ln(x))^m}{m!n^{m-2}}\end{aligned} \tag{7.1.352}$$

  And finally:

  $$\lim_{x\rightarrow+\infty}n(\sqrt[n]{x}-1)=\lim_{x\rightarrow+\infty}\ln(x)+\frac{1}{n}\sum_{m=2}^{+\infty}\frac{(\ln(x))^m}{m!n^{m-2}}=\ln(x) \tag{7.1.353}$$

29. We want to show if:

$$\lim_{n\rightarrow+\infty}\left(1+\frac{1}{2}+\frac{1}{3}+\ldots+\frac{1}{n}\right)=+\infty \tag{7.1.354}$$

There are many ways to handle this sequence. Let us use calculus techniques again. Consider the function:

$$f(x)=\frac{1}{x},\qquad \text{for } x\geq 1 \tag{7.1.355}$$

We have:

$$\int\limits_{n}^{n+1}\frac{1}{x}\mathrm{d}x=[\ln(x)]_n^{n+1}=\ln(n+1)-\ln(n) \tag{7.1.356}$$

and:

$$\int\limits_{1}^{n+1}\frac{1}{x}\mathrm{d}x=[\ln(x)]_1^{n+1}=\ln(n+1) \tag{7.1.357}$$

for any $n \geq 1$. Note that for any $x \in [n, n+1]$, we have:

$$\frac{1}{n+1} \leq \frac{1}{x} \leq \frac{1}{n} \qquad (7.1.358)$$

hence:

$$\int_{n}^{n+1} \frac{1}{n+1}\mathrm{d}x \leq \int_{n}^{n+1} \frac{1}{x}\mathrm{d}x \leq \int_{n}^{n+1} \frac{1}{n}\mathrm{d}x \qquad (7.1.359)$$

which gives:

$$\frac{1}{n+1} \leq \int_{n}^{n+1} \frac{1}{x}\mathrm{d}x \leq \frac{1}{n} \qquad (7.1.360)$$

Since:

$$\int_{1}^{n+1} \frac{1}{x}\mathrm{d}x = \int_{1}^{2} \frac{1}{x}\mathrm{d}x + \int_{2}^{3} \frac{1}{x}\mathrm{d}x + \ldots + \int_{n-1}^{n} \frac{1}{x}\mathrm{d}x + \int_{n}^{n+1} \frac{1}{x}\mathrm{d}x \qquad (7.1.361)$$

we get:

$$\frac{1}{2} + \ldots + \frac{1}{n+1} \leq \int_{1}^{n+1} \frac{1}{x}\mathrm{d}x \leq 1 + \frac{1}{2} + \ldots + \frac{1}{n} \qquad (7.1.362)$$

In particular, we have:

$$\ln(n+1) = \int_{1}^{n+1} \frac{1}{x}\mathrm{d}x \leq 1 + \frac{1}{2} + \ldots + \frac{1}{n} \qquad (7.1.363)$$

Therefore, since $\lim_{n\rightarrow+\infty} \ln(n+1) = +\infty$, we must have:

$$\lim_{n\rightarrow+\infty} 1 + \frac{1}{2} + \ldots + \frac{1}{n} = +\infty \qquad (7.1.364)$$

We will stop here the list of common epsilon-delta limits and epsilon-delta continuities as it is almost without end! And the reader must keep in mind that we have focused only on univariate functions here above and that most of the examples were only for real valued functions (only two were in the complex planes)...

Most engineers don't like this topic but don't forget that it's the only rigorous way to show that a function can be differentiate or integrate (among other important application for professional mathematicians and theoretical physicists)!

To summarize here is a table with the most important limits:

Most common limits		
$\lim\limits_{z\to a} c^{te}=c^{te}$	$\lim\limits_{x\to a} x^n=a^n$	$\lim\limits_{x\to 0} x^2\sin\left(\dfrac{1}{x}\right)$
$\lim\limits_{z\to +\infty}\left(1+\dfrac{a}{x}\right)^z=e^a$	$\lim\limits_{x\to 0}\dfrac{e^x-1}{x}=1$	$\lim\limits_{x\to 0}\sin(x)=0$
$\lim\limits_{x\to 0}\tan(x)=0$	$\lim\limits_{z\to 0}(1+x)^{1/x}=e$	$\lim\limits_{x\to a}\dfrac{x-a}{x^n-a^n}=\dfrac{1}{na^{n-1}}$
$\lim\limits_{x\to 0}\dfrac{\sin(x)}{x}=1$	$\lim\limits_{x\to 0}\dfrac{\log(1+x)}{x}=1$	$\lim\limits_{x\to 0}\dfrac{\arcsin(x)}{x}=1$
$\lim\limits_{z\to 0}\dfrac{\arctan(x)}{x}=1$	$\lim\limits_{z\to 0}\dfrac{a^x-1}{x}=\ln(a)$	$\lim\limits_{x\to 0}\dfrac{1-\cos(x)}{x}=0$
$\lim\limits_{x\to 0^+} x\ln(x)=0$	$\lim\limits_{z\to +\infty}\dfrac{\ln(x)}{x}=0$	$\lim\limits_{x\to 0}(1+\sin(x))^{1/x}=e$
$\lim\limits_{x\to +\infty} x-\sqrt{x^2-a^2}=0$	$\lim\limits_{x\to 0}\dfrac{\tan(x)-\sin(x)}{x^3}=\dfrac{1}{2}$	$\lim\limits_{x\to +\infty}\dfrac{\log^p(x)}{x^q}=0$
$\lim\limits_{n\to +\infty}\left(1+\dfrac{1}{2}+\dfrac{1}{3}+\ldots+\dfrac{1}{n}\right)=+\infty$	$\lim\limits_{n\to +\infty}\sqrt[n]{a}=1$	$\lim\limits_{x\to 0}\cos(x)=1$
$\lim\limits_{x\to a}\dfrac{x^n-a^n}{x-a}=na^{n-1}$	$\lim\limits_{z\to 0}\dfrac{\tan(x)}{x}=1$	$\lim\limits_{z\to +\infty} x^{1/x}=1$
$\lim\limits_{x\to 0} x^x=1$	$\lim\limits_{z\to 0}\dfrac{\tan(x)}{x}=1$	$\lim\limits_{x\to +\infty} n(\sqrt[n]{x}-1)=\log(x)$

Table 7.5: **Most common limits**

Remark

In some of the proofs of usual limits seen earlier above the reader may have noticed that sometimes that arguments turn out to involve not just ε but a constant multiple of it. This may occur for instance when the limit involves a sum or several arithmetic processes.

But is $K\varepsilon$ just as good as ε? If we en upd with a proof with 2ε, or 22ε, or 0.001ε, that's just as good as coming out with ε! Indeed if ε is an arbitrary small number, so is 22ϵ and 0.001ε. Therefore, if we can prove something is less than $K\varepsilon$, you have shown that it can be made as small as desired.

We formulate this as a general principle, the "K-ε principle". This isn't a standard term in analysis, so don't use it when you go to your next mathematics congress, but it is useful to name an idea that will recur often.

7.1.2.1.3 Limit laws

We now take a look at the "limit laws", the individual properties limits in the univariate case. The proofs will be omitted as it is quite intuitive but any reader can request us the proof of one of them if needed!

Let $f(x)$ and $g(x)$ be defined for all $x\neq a$ over some open interval containing a. Assume that L and M are real numbers such that:

$$\lim_{x\to a} f(x)=L \qquad \text{and} \qquad \lim_{x\to a} g(x)=M \tag{7.1.365}$$

Let c^{te} be a constant. Then, each of the following statements holds:

- The sum law for limits gives:

$$\lim_{x\rightarrow a}(f(x)+g(x))=\lim_{x\rightarrow a}f(x)+\lim_{x\rightarrow a}g(x)=L+M \tag{7.1.366}$$

- The difference law for limits gives:

$$\lim_{x\rightarrow a}(f(x)-g(x))=\lim_{x\rightarrow a}f(x)-\lim_{x\rightarrow a}g(x)=L-M \tag{7.1.367}$$

- Constant multiple law for limits:

$$\lim_{x\rightarrow a}c^{te}f(x)=c^{te}\lim_{x\rightarrow a}f(x)=c^{te}L \tag{7.1.368}$$

- Product law for limits:

$$\lim_{x\rightarrow a}f(x)g(x)=\lim_{x\rightarrow a}f(x)\lim_{x\rightarrow a}g(x)=L\cdot M \tag{7.1.369}$$

- Quotient law for limits:

$$\lim_{x\rightarrow a}\frac{f(x)}{g(x)}=\frac{\lim\limits_{x\rightarrow a}f(x)}{\lim\limits_{x\rightarrow a}g(x)}=\frac{L}{M} \tag{7.1.370}$$

  for $M\neq 0$.

- Power law for limits:

$$\lim_{x\rightarrow a}(f(x))^n=\left(\lim_{x\rightarrow a}f(x)\right)^n=L^n \tag{7.1.371}$$

  for every positive integer n.

- Root law for limits:

$$\lim_{x\rightarrow a}\sqrt[n]{f(x)}=\sqrt[n]{\lim_{x\rightarrow a}f(x)}=\sqrt[n]{L} \tag{7.1.372}$$

  for all L if n is odd and for $L\geq 0$ if n is even.

7.1.2.1.4 Asymptotes

The term "asymptote" is used in mathematics to precise possible properties of an infinite branch of curve which growth tends to an infinitesimal value.

In analytic geometry, an asymptote of a curve is simply said to be a line such that the distance between the curve and the line approaches zero as they tend to infinity. In some contexts, such as algebraic geometry, an asymptote is defined as a line which is tangent to a curve at infinity.

The study of asymptotic behavior is particularly developed in the studies of functions. In the scientific field, it is common to study time-dependent functions (evolution of populations, chemical or nuclear reactions, temperature graphs, oscillation of a shock absorber). One of the researcher's objectives is then to know the state at the end of the experiment, that is to say when a large interval of time has passed. The objective is then not to know the intermediate variations, but to determine the stable, infinite behavior of the measured phenomenon. The researcher therefore studies the asymptotic behavior of his function with the tools that mathematics offers him.

Remark

The word "asymptote" is derived from the Greek and means "not falling together".

Definitions (#7.1.277):

D1. When the limit of a function $f(x)$ tends to a constant c^{te} when $x \to \pm\infty$, then the graphical representation of this function leads us to draw a horizontal line that we name "horizontal asymptote" which equation satisfies:

$$\lim_{x\to\pm\infty} f(x) - c^{te} = f(x_0) \tag{7.1.373}$$

D2. When the limit of a function $f(x)$ tends to $\pm\infty$ when $x \to a_{+,-}$, then the graphical representation of this function leads us to draw a vertical line that we name "vertical asymptote" which equation satisfies:

$$\lim_{x\to a_{+,-}} f(x) \pm \infty = 0 \tag{7.1.374}$$

Vertical asymptotes is the typical symptom of a division by zero in a fraction and has a very important place in physics. The syndrome is also named a "singularity".

✍**Example:**

The graph of the function:

$$f(x) = \frac{1}{x-1} \tag{7.1.375}$$

has the straight lines of $x = 1$ as vertical asymptote and $y = 0$ as horizontal asymptote:

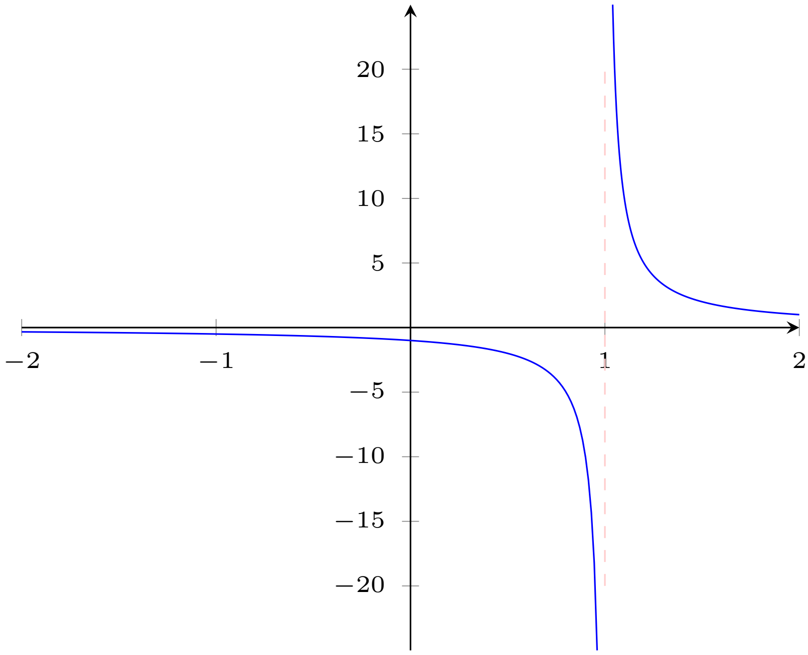


Figure 7.51: **Graphical representation of a horizontal and vertical asymptote**

D3. The straight line of equation $y=ax+b$ is an "oblique asymptote" or "slant asymptote" of a curve of function $f(x)$ if:

$$\lim_{x\to\pm\infty} f(x)-(ax+b)=0 \tag{7.1.376}$$

the values of a and b can be easily found using the following relations:

$$\begin{gathered}\lim_{x\to\pm\infty}\frac{f(x)}{x}\\ \lim_{x\to\pm\infty} f(x)-ax\end{gathered} \tag{7.1.377}$$

> Caution! A curve may have two distinct oblique asymptotes in $+\infty$ and $-\infty$.

To find a possible oblique asymptote, one must already be certain that the function $f(x)$ admits an infinite limit in $+\infty$ or $-\infty$ then only we look for the limits at $-\infty$ and $+\infty$ of $f(x)/x$ and $f(x)-ax$.

Three typical cases can be considered for oblique asymptotes:

(a) The representative curve of $f(x)$ has for asymptotical direction the affine equation $y=ax$:

$$\lim_{x\to\pm\infty}\frac{f(x)}{x}=a \tag{7.1.378}$$

✍**Example:**

The graph of the function:

$$f(x) = x + \frac{1}{x} \tag{7.1.379}$$

has the straight line of $y = x$ as oblique asymptote:

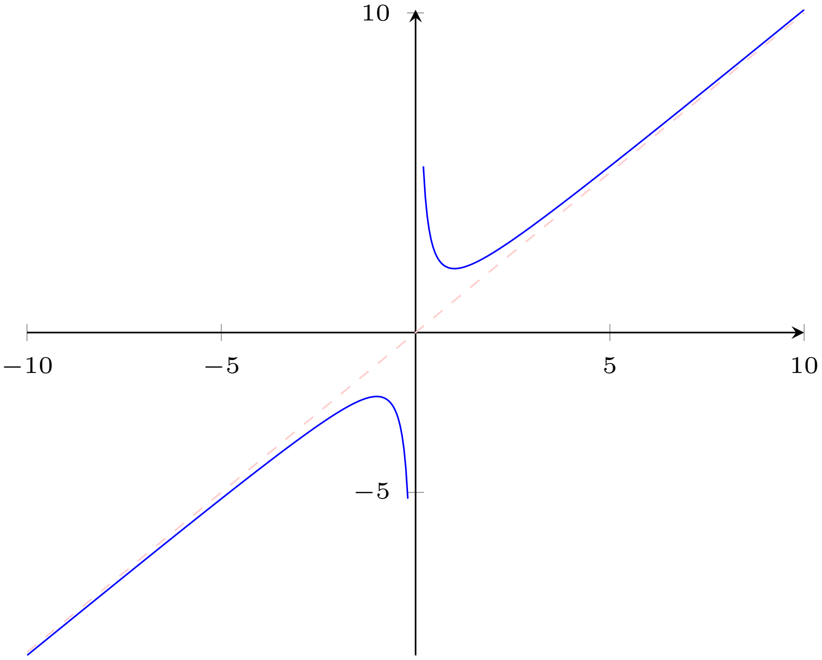

Figure 7.52: **Graphical representation of an oblique affine asymptote**

(b) The representative curve of $f(x)$ has an infinite branch (this branch has not close form asymptote) and the only one thing we can say is that x-axis is the direction of this asymptote. Such an asymptote exists when:

$$\lim_{x \to \pm\infty} \frac{f(x)}{x} = 0 \tag{7.1.380}$$

✍**Example:**

The functions $f(x)=\sqrt{x}$ (in red) or $\ln(x)$ (in green) have a limit $f(x)/x$ equal to 0 and both have a "parabolic branch" of direction following the x-axis:

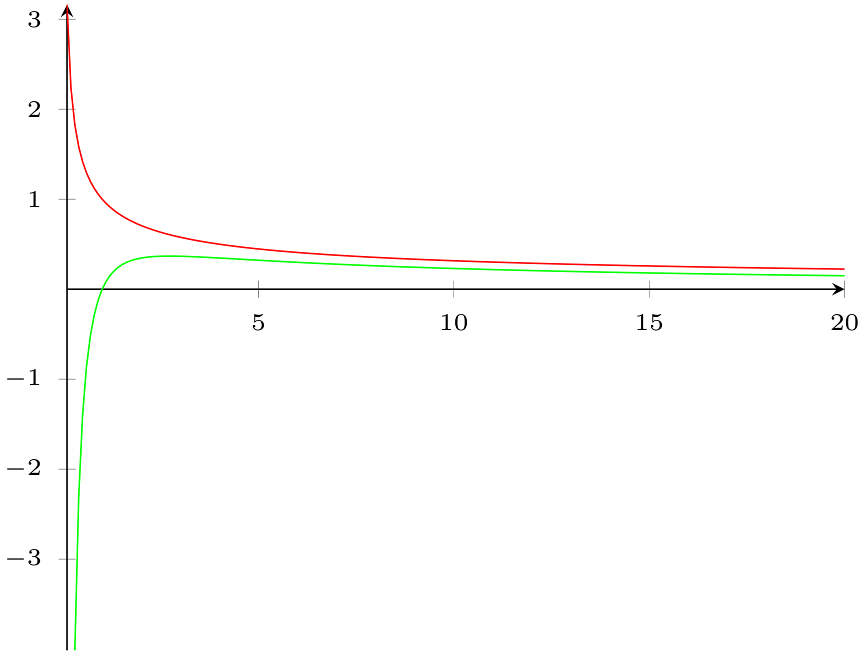

Figure 7.53: **Graphical representation of a parabolic branch example following x-axis**

(c) The representative curve of $f(x)$ has an infinite branch (this branch has not close form asymptote) and the only one thing we can say is that y-axis is the direction of this asymptote (we then also speak of "parabolic branch"):

$$\lim_{x\to\pm\infty}\frac{f(x)}{x}=\pm\infty \tag{7.1.381}$$

(d) A function $f(x)$ is say to have a "curvilinear asymptote" if it satisfies:

$$\lim_{x\to\pm\infty} f(x)=P_n(x) \tag{7.1.382}$$

for $n>1$ where for recall $P_n(x)$ is a polynomial of degree n.

✍**Example:**

The function :

$$f(x)=\frac{x^3+2x^2+3x+4}{x} \tag{7.1.383}$$

has a curvilinear asymptote that is:

$$x^2+2x^2+3x \tag{7.1.384}$$

Indeed:

$$\lim_{x\to\pm\infty} f(x)=\frac{x^3+2x^2+3x+4}{x}=x^2+2x^2+3x+\frac{4}{x} \tag{7.1.385}$$

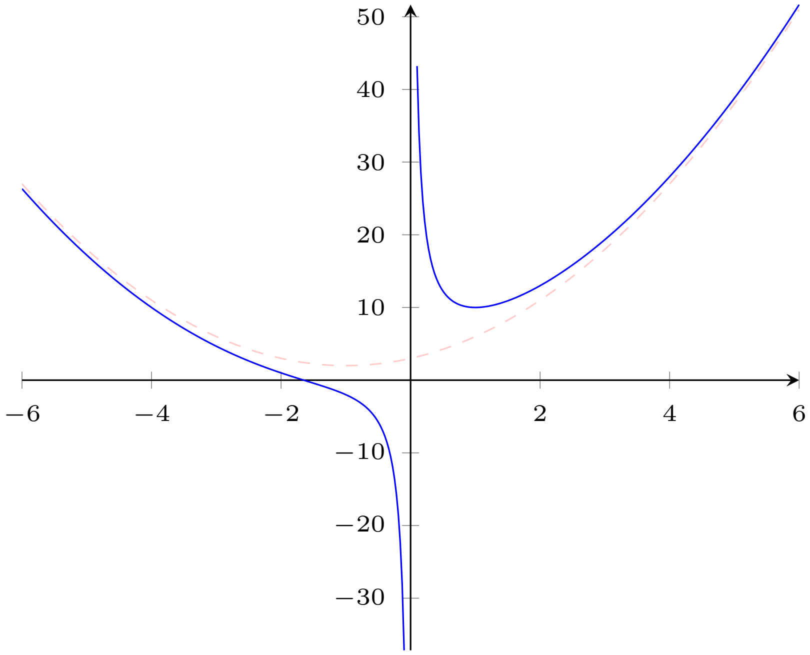

Figure 7.54: **Graphical representation of a curvilinear asymptote of equation** x^2+2x+3

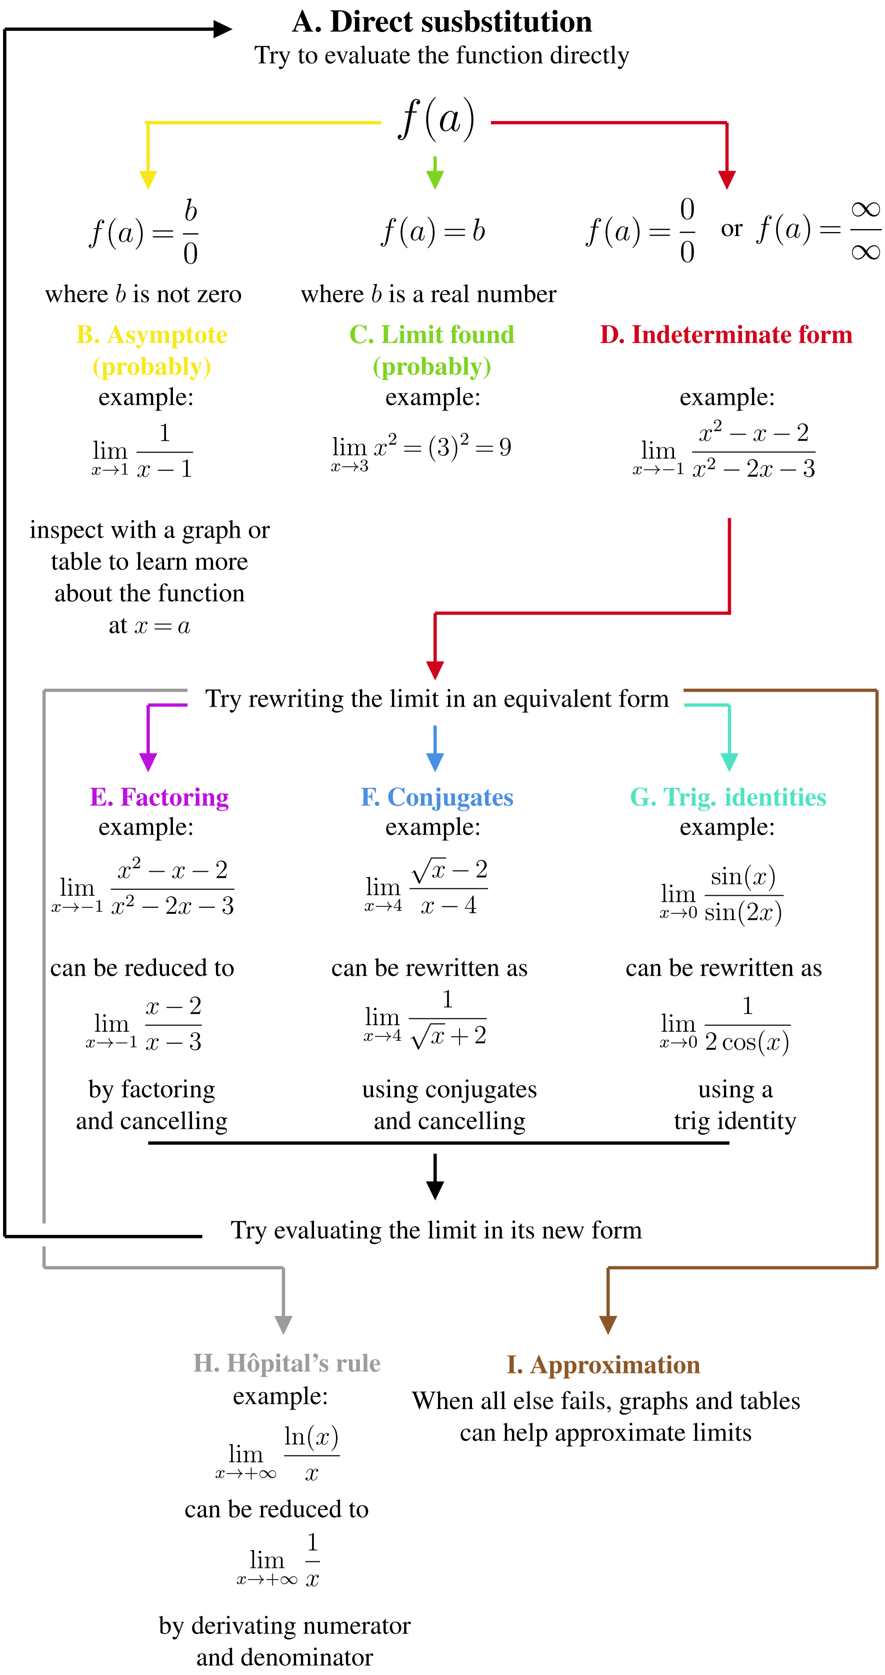
There are many techniques for finding limits that apply in various conditions. It's important to know all these techniques, but it's also important to know when to apply which technique. Some basic techniques who doesn't involve derivation are:

Calculating $\lim\limits_{x\to 0} f(x)$



A. Direct susbstitution
Try to evaluate the function directly
$f(a)$
$f(a)=\frac{b}{0}$
where b is not zero
B. Asymptote (probably)
example:
$\lim\limits_{x\to 1}\frac{1}{x-1}$
inspect with a graph or table to learn more about the function at $x=a$
$f(a)=b$
where b is a real number
C. Limit found (probably)
example:
$\lim\limits_{x\to 3} x^2=(3)^2=9$
$f(a)=\frac{0}{0}$ or $f(a)=\frac{\infty}{\infty}$
D. Indeterminate form
example:
$\lim\limits_{x\to -1}\frac{x^2-x-2}{x^2-2x-3}$
Try rewriting the limit in an equivalent form
E. Factoring
example:
$\lim\limits_{x\to -1}\frac{x^2-x-2}{x^2-2x-3}$
can be reduced to
$\lim\limits_{x\to -1}\frac{x-2}{x-3}$
by factoring and cancelling
F. Conjugates
example:
$\lim\limits_{x\to 4}\frac{\sqrt{x}-2}{x-4}$
can be rewritten as
$\lim\limits_{x\to 4}\frac{1}{\sqrt{x}+2}$
using conjugates and cancelling
G. Trig. identities
example:
$\lim\limits_{x\to 0}\frac{\sin(x)}{\sin(2x)}$
can be rewritten as
$\lim\limits_{x\to 0}\frac{1}{2\cos(x)}$
using a trig identity
Try evaluating the limit in its new form
H. Hôpital's rule
example:
$\lim\limits_{x\to +\infty}\frac{\ln(x)}{x}$
can be reduced to
$\lim\limits_{x\to +\infty}\frac{1}{x}$
by derivating numerator and denominator
I. Approximation
When all else fails, graphs and tables can help approximate limits

Figure 7.55: **Basic techniques for finding limits**

7.1.2.1.5 Discontinuities

Continuous functions are of utmost importance in mathematics! However, not all functions are continuous. If a function is not continuous at a point in its domain, one says that it has a "discontinuity" there. The set of all points of discontinuity of a function may be a discrete set, a dense set, or even the entire domain of the function.

In practice we consider the four following types of discontinuities (more details and examples follow after the figure!):

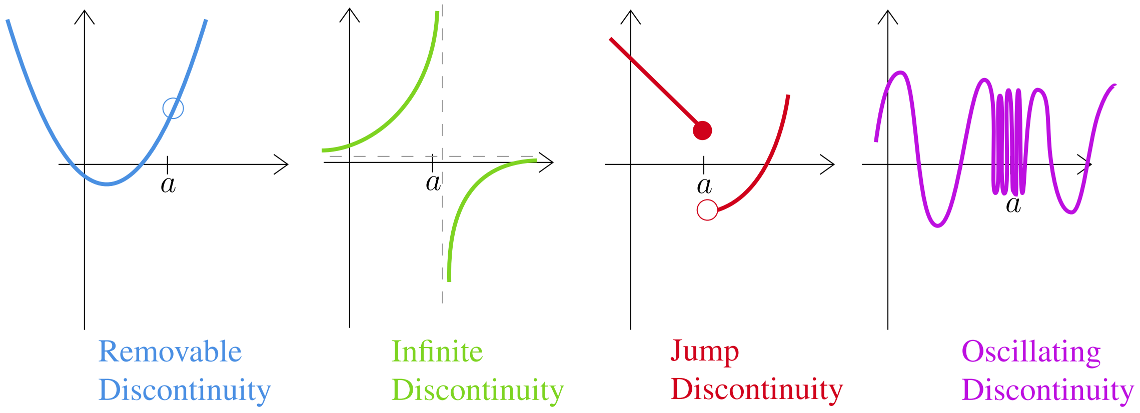


Figure 7.56: **Common types of discontinuities**

For each of the following, consider a real valued function $f(x)$ of a real variable x, defined in a neighborhood of the point x_0 at which $f(x)$ is discontinuous!

Definitions (#7.1.278):

D1. Removable discontinuity:

Consider the following fraction:

$$f(x)=\frac{x^3-3x^2+2x}{x-1} \tag{7.1.386}$$

It seems to have a discontinuity (singularity) in $x_0=1$, but in facts it's removable one (or an "apparent singularity"). Indeed we can easily remove it:

$$f(x)=\frac{x^3-3x^2+2x}{x-1}=\frac{x(x^2-3x+2)}{x-1}=\frac{x(x-1)(x-2)}{x-1}=x(x-2) \tag{7.1.387}$$

And that's it! No discontinuity anymore is visible nor exist. And obviously using the techniques we have seen earlier, it is immediate that this function is epsilon-delta continuous!

The one-sided limit from the negative direction:

$$L^-=\lim_{x\to x_0^-}f(x) \tag{7.1.388}$$

and the one-sided limit from the positive direction:

$$L^+=\lim_{x\to x_0^+}f(x) \tag{7.1.389}$$

at x_0 both exist, are finite, and are equal to $L = L^- = L^+$. In other words, since the two one-sided limits exist and are equal, the limit L of $f(x)$ as x approaches x_0 exists and is equal to this same value. If the actual value of $f\left(x_0\right)$ is not equal to L, then x_0 is named a "removable discontinuity".

D2. Infinite discontinuity/Essential discontinuity:

Consider the function:

$$f(x) = \frac{1}{x} \tag{7.1.390}$$

Notice that as the value of x approaches 0 from the left, the function grows infinitely smaller! Likewise, on the right of the y-axis, as the value of x approaches 0, the function increases infinitely!

How do we prove that this function doesn't have a limit at $x_0 = 0$ using epsilon-delta discontinuity?

That's quite simple! Remember that a function is epsilon-delta continuous if:

$$\forall x \in D \forall \varepsilon > 0 \exists \delta > 0 \forall x_0 \in D : |x - x_0| < \delta \Rightarrow |f(x) - f(x_0)| < \varepsilon \tag{7.1.391}$$

So if we choose $x_0 = 0$ that means obviously if a limit L would exist at this point that:

$$\forall x \in D \forall \varepsilon > 0 \exists \delta > 0 \forall x_0 \in D : |x| < \delta \Rightarrow \left| \frac{1}{x} - L \right| < \varepsilon \tag{7.1.392}$$

Hence:

$$\forall x \in D \forall \varepsilon > 0 \exists \delta > 0 \forall x_0 \in D : 0 < x < \delta \Rightarrow -\varepsilon < \frac{1}{x} - L < +\varepsilon \tag{7.1.393}$$

Let us choose arbitrarily $\varepsilon = 1$ and focus on the right part of the x axis (hence $L > 0$). Therefore if L exist, we should have:

$$\frac{1}{x} - L < +\varepsilon \Rightarrow \frac{1}{x} - L < 1 \tag{7.1.394}$$

ie:

$$\frac{1}{x} < L + 1 \tag{7.1.395}$$

And as we should be able to choose any $0 < x < \delta$ this contradicts obviously the previous inequality as we may always choose a x that gives $1/x > L + 1$. Hence the contradiction, therefore the limit L doesn't exist and $f(x) = 1/x$ is not epsilon-delta continuous at $x_0 = 0$!

Hence a function has an infinite discontinuity if:

$$\lim_{x \to x_0} f(x) = \pm\infty \tag{7.1.396}$$

In this example, both L^- and L^+ do not exist in $\mathbb{R}$, thus satisfying the condition of essential discontinuity. So x_0 is an "essential discontinuity", an "infinite discontinuity" or a "discontinuity of the second kind".

D3. Jump discontinuity:

Consider the function:

$$f(x) = \begin{cases} 2x+3, x \geq 1 \\ 2x-2, x < 1 \end{cases} \tag{7.1.397}$$

Then, the point $x_0 = 1$ is a jump discontinuity.

In this case, a single limit does not exist because the one-sided limits, $L^-$and L^+exist and are finite, but are not equal: since, $L^- \neq L^+$, the limit L does not exist. Then, x_0 is called a jump discontinuity, step discontinuity, or discontinuity of the first kind. For this type of discontinuity, the function f may have any value at x_0.

Let us prove that with the epsilon-delta continuity!

We have $f(1) = 5$. So to show that $f(x)$ is not continuous at $x = 1$, it is enough to show that it is not true that $\lim_{x\to 1} f(x) = 5$.

Suppose to the contrary that the limit exists and is equal to 5. Then for any $\varepsilon > 0$, there is a $\delta > 0$ such that if $|x-1| < \delta$, then $|f(x)-5| < \varepsilon$.

Pick $\varepsilon = 1/2$. We show there is no δ with the required property.

If $x < 1$, then $f(x) < 1$. In particular, if $x < 1$, then $|f(x)-5| > 4$. It follows that there is no δ such that $|x-1| < \delta$ guarantees that $|f(x)-5| < \varepsilon$.

D4. Oscillating discontinuity:

Consider the function:

$$f(x) = \sin\left(\frac{1}{x}\right) \tag{7.1.398}$$

with it's corresponding plot:

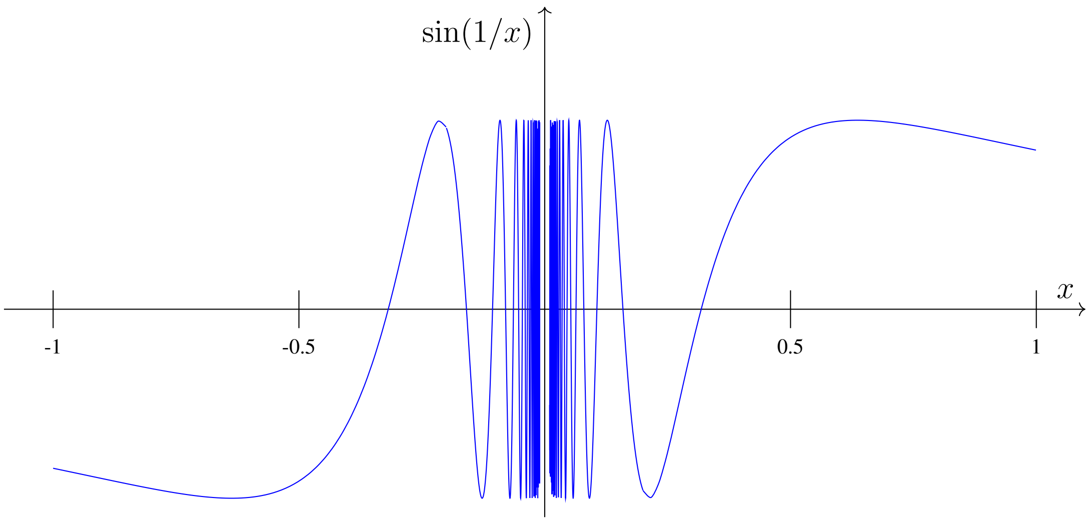

Figure 7.57: **Example of a famous oscillating discontinuity**

Then, the point $x_0 = 0$ is an oscillating discontinuity.

Or a more formal approach: Let $f(x) = \sin(1/x)$.

If $f(x)$ attains a limit L then there exists a $\delta > 0$ for every $\varepsilon > 0$ such that $|f(x) - L| < \varepsilon$ such that $0 < |x - 0| < \delta$.

Considering it from the right we have $0 < x < \delta$ or $+\infty < 1/x < 1/\delta$. Which means There are infinite number of $1/x$ of the form $2n\pi$. Which means the function is oscillating in the interval and the limit does not exist!

It's quite a fascinating result to imagine that for such a simple deterministic function (and that's not chaos physics nor quantum physics stuff but pure mathematics!) leads to a non-deterministic result... That's a nice example that even in pure mathematics not everything leads to perfect known result!

Oscillating discontinuities are bounded. In other words, their oscillations stay between certain lines. For example, the function might be bounded between a high point of $y = +3$ and a low point of $y = -1$. If the function is unbounded at one or both sides, it's an infinite discontinuity. In other words, the function must be completely bounded at all points in order for there to be an oscillating discontinuity. In addition, the one sided limits do not exist at all.

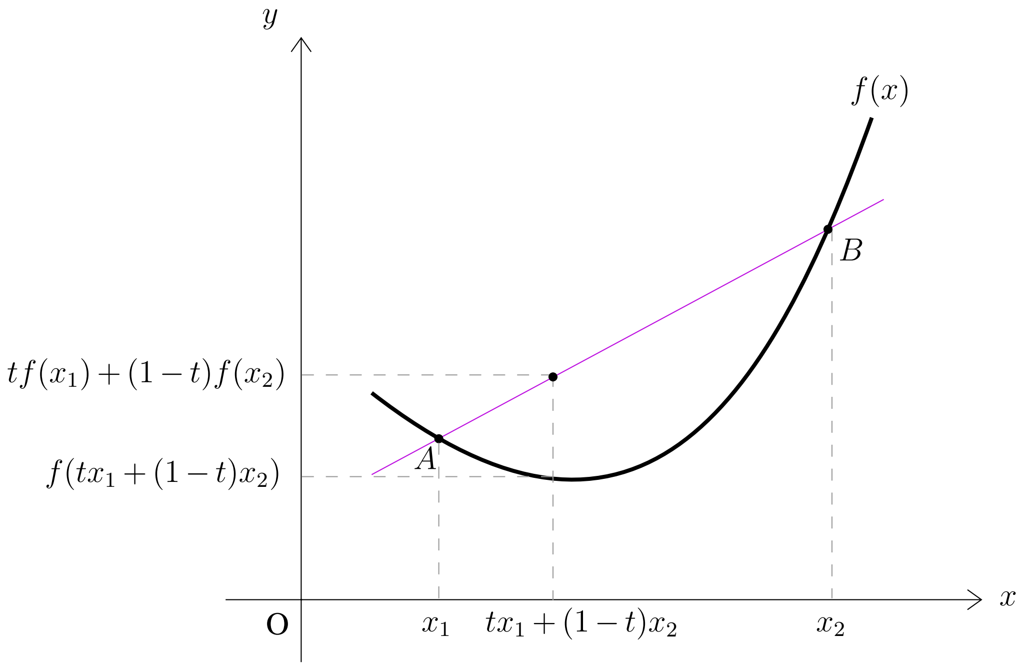
Remark

Oscillating discontinuities are considered by mathematicians as a sub-type of "essential discontinuities" or "non-repairable discontinuities".

7.1.2.2 Concavity/Convexity of a function

We will define now a property which at first sight may seem of no interest as it is so trivial but which we shall find in the section of Statistics for the demonstration of an important relation named "Jensen inequality" and which is of major importance Finance and Insurance for the valuation of options and premiums (see section Economy page 7674) and especially for the application of the Jensen's inequality (see section Statistics page 576).

Consider the following figure:



Definition (#7.1.279): In mathematics, a real function of a real variable is say to a "convex function" if, viewed from below, its graph is convex (in bump); we mean that if A and B are two points of the graph of the function, the segment $\overline{AB}$ is entirely situated above the graph. It is the same to say that the "epigraph" (the set of points above the graph) is a concave set. Conversely, a function whose graph, as seen from below, is seen as a cave, is say to be a "concave function". It is the same to say that the "hypograph" (the set of points below) is a convex set.

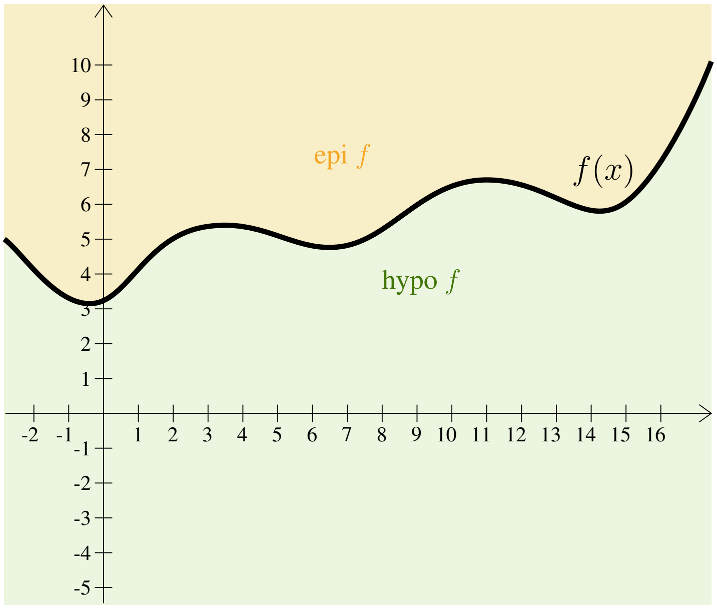


Figure 7.58: **Epigraph and Hypograph of a function**

By specifying by the values of the function what are the points A and B above, we get often an equivalent definition of the convexity of a function: a function defined on a real interval I is convex when, for any x_1 and x_2 of I and all t in $[0,1]$ we have:

$$\boxed{f(tx_1+(1-t)x_2)\leq tf(x_1)+(1-t)f(x_2)} \tag{7.1.399}$$

When the inequality is strict, then we obviously speak of a "strictly convex function".

Remark

Without proof, just by looking to the above chart, we will assume quite obvious that convexity implies $f''(x)\geq 0$ for all x. Just as before, strict convexity occurs when the inequality is strict.

By extension (common sense from our point of view), a function f is concave if $-f$ is convex (which is trivial with the payoff function - see section Economy page 7674 - profile of options from seller or buyer point of view).

✍**Examples:**

E1. Let us consider $f(x)=x^2$. The first derivative of $f(x)$ is given by $\frac{\mathrm{d}}{\mathrm{d}x}f=2x$ and its second derivative by $\frac{\mathrm{d}^2}{\mathrm{d}x^2}f=2$. Since this is always strictly greater than 0, we have proven that $f(x)=x^2$ is strictly convex.

E2. Let us consider $f(x)=\log(x)$. The first derivative is $\frac{\mathrm{d}}{\mathrm{d}x}f=\frac{1}{x}$ and its second derivative is given by $\frac{\mathrm{d}^2}{\mathrm{d}x^2}f=-\frac{1}{x^2}$. Since this is negative for all $x>0$, we have proven that $\log(x)$ is a concave function over $\mathbb{R}_+$.

7.1.2.3 Euler theorem for homogeneous functions

We have to introduce now a definition and a theorem that will be very important for quite advanced concepts in our study of Physics later in this textbook.

Definition (#7.1.280): A "homogeneous function" is one with multiplicative scaling behaviour: if all its arguments are multiplied by a factor, then its value is multiplied by some power of this factor. For example, a homogeneous real-valued function of two variables x and y is a real-valued function that satisfies the condition $f(tx,ty)=t^k f(x,y)$ for some constant k and all real numbers $t\in\mathbb{R}^*$. The constant k is named the "degree of homogeneity".

More generally, if $f:\mathbb{R}^n\mapsto\mathbb{R}$ is a function between two vector spaces over a field F, and k is an integer, then f is said to be homogeneous of degree k if:

$$f(tx,ty,ty)=t^k f(x,y,z) \tag{7.1.400}$$

or more commonly written:

$$f(t\vec{x})=t^k f(\vec{x}) \tag{7.1.401}$$

✍**Example:**

The function $f(x,y)=x^2+y^2$ is homogeneous of degree 2. Indeed:

$$f(tx,ty)=(tx)^2+(ty)^2=t^2(x^2+y^2)=t^2 f(x,y) \tag{7.1.402}$$

Now let us suppose $f:\mathbb{R}^n\mapsto\mathbb{R}$ is continuously differentiable on $\mathbb{R}$. We know that a function is homogeneous of degree k if:

$$f(t\vec{x})=t^k f(\vec{x}) \tag{7.1.403}$$

Differentiating both sides with respect to t, we get:

$$\frac{\mathrm{d}f(t\vec{x})}{\mathrm{d}t}=\sum_{i=1}^{n}\frac{\partial f(tx)}{\partial x_i}x_i=kt^{k-1}f(x) \tag{7.1.404}$$

by the total exact differential chain rule of f.

So the "Euler theorem for homogeneous functions" can be summarized as following:

$$\boxed{f(tx,ty,ty)=t^k f(x,y,z)\Leftrightarrow\sum_{i=1}^{n}\frac{\partial f(tx)}{\partial x_i}x_i=kt^{k-1}f(x)} \tag{7.1.405}$$

Remark

Remember that we have proved in the section of Differential and Integral Calculus (see page 1466) that:

$$\mathrm{d}f=\frac{\partial f}{\partial x}\mathrm{d}x+\frac{\partial f}{\partial y}\mathrm{d}y \tag{7.1.406}$$

Therefore:

$$\frac{\mathrm{d}f}{\mathrm{d}t}=\frac{\partial f}{\partial x}\frac{\mathrm{d}x}{\mathrm{d}t}+\frac{\partial f}{\partial y}\frac{\mathrm{d}y}{\mathrm{d}t}=\frac{\partial f}{\partial x}\frac{\mathrm{d}(tx)}{\mathrm{d}t}+\frac{\partial f}{\partial y}\frac{\mathrm{d}(ty)}{\mathrm{d}t}=\frac{\partial f}{\partial x}x+\frac{\partial f}{\partial y}y \tag{7.1.407}$$

Then if we choose to set with the special case $k=1$ (it's the case that will interest us the most in Physics) then the above becomes:

$$\sum_{i=1}^{n}\frac{\partial f(x)}{\partial x_i}x_i=f(x) \tag{7.1.408}$$

or explicitly for $n=2$:

$$x\frac{\partial f}{\partial x}+y\frac{\partial f}{\partial y}=f(x,y) \tag{7.1.409}$$

if $f(tx)$ is homogeneous of degree 1.

This is an important result we will need in Lagrangian Mechanics that will be useful for the study of the Lagrangian of a free particle in Special Relativity and in Quantum Cosmology.

7.1.3 Logarithms

We hesitated to put the definition of logarithms in the section Calculus. After a moment of reflection, we decided it was better to put it in this section because to understand it well, we must be aware of the concept of limits, of definition domain and of the power function. We hope that our choice will suit you best.

Given the power (bijective) function of any base where $a \in \mathbb{R}_{+}^{*}/1$ (we exclude 1 otherwise it is not bijective) and denoted for recall by:

$$f(x)=a^x \tag{7.1.410}$$

for which it corresponds to each real number x, exactly one positive number a^x (the image set of the function is in $\mathbb{R}$) such as the powers calculations rules are applicable (see section Calculus page 1353).

We know that for such a function that if $a>1$, then $f(x)$ is an increasing and positive (monotone) in $\mathbb{R}$, and if $0<a<1$, then $f(x)$ is positive and decreasing (monotone) in $\mathbb{R}$.

Remarks

R1. If $a>1$, when x decreases to negative values, the graph of $f(x)$ approaches the x-axis. Thus, the x axis is a horizontal asymptote. When x increases in positive values, the graph rises quickly. This type of change is characteristic of the "law of exponential of growth" and $f(x)$ is sometimes named "growing function"... If $0<a<1$, when x increases, the graph tends asymptotically to the x-axis. This type of variation is known as an "exponential decay".

R2. By studying a^x, we exclude the case where $a \leq 0$ and $a=1$. Notice that if $a<0$, then a^x is not a real number for many values of x (we recall that the whole image set is forced to $\mathbb{R}$ in our previous definition). If $a=0$, the $a^0=0$ is not defined. Finally, if $a=1$, then $a^x=1$ for all x and the graph of $f(x)$ is a horizontal line.

As the power function $f(x)$ is bijective then there exists an inverse function $f^{-1}(x)$ and is named "logarithm function" of base a and is denoted by:

$$f^{-1}(y)=\log_a(y) \tag{7.1.411}$$

and therefore:

$$x=\log_a(y) \tag{7.1.412}$$

if and only if $y=a^x$.

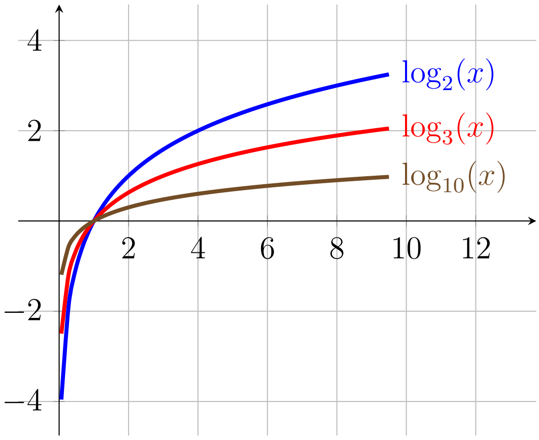
More generally it is defined by:

$$\boxed{\log_a(y)=x \Leftrightarrow a^x=y \qquad a>0, a\neq 1} \tag{7.1.413}$$

Considering $\log_a(x)$ as an exponent, we have the following properties:

Properties	**Justification**
$\log_a 1 = 0$	$a^0 = 1$
$\log_a a = a$	$a^1 = a$
$\log_a a^x$	$a^x = a^x$
$a^{\log_a(x)} = x$	$a^{\log_a(x)} = a^y = x$

Table 7.6: **Properties of the logarithm in base a**



Remarks

R1. The word "logarithm" means "number of logos", "logos" meaning "reason" or "ratio".

R2. The logarithm and power functions are defined by their bases (the number a). When using a power of 10 as a base $(10, 100, 1000, \ldots)$ then we speak of "common system" because they have for $\log$ successive integers.

R3. The integer part of the logarithm is named the "characteristic".

There are two types of logarithms that we find almost exclusively in mathematics and physics: the logarithm of base 10, logarithm of base e (the latter often named "natural logarithm") and logarithm of base 2 for information theory.

First the one in base 10 (the most used on graphical representations):

$$f(x) = \log_{10}(x) \tag{7.1.414}$$

abusively noted:

$$f(x) = \log(x) \tag{7.1.415}$$

and the base (Eulerian) e:

$$f(x) = \log_e(x) \tag{7.1.416}$$

historically noted:

$$\boxed{f(x) = \ln(x)} \tag{7.1.417}$$

the "n" meaning "Napierian".

Remark

Historically, it is John Napier (11550-11617 according to holocene calendar) whose name was Latinized "Napier" that we own the study of logarithms and the name of "natural logarithms" which aimed to facilitate greatly the time for manual calculations.

In English for the logarithm function in base-10 logarithmic we need to calculate:

$$f(x)=\log(x) \tag{7.1.418}$$

ask the following question: at what power $n \in \mathbb{R}$ should we raise 10 to get x?

Formally, this consist to solve the equation:

$$10^n=x \tag{7.1.419}$$

or written in another way:

$$10=\sqrt[n]{x} \tag{7.1.420}$$

with x being known and therefore in base 10:

$$\log(x)=n \tag{7.1.421}$$

To work with exponents of different bases, you also need its opposite operation, the logarithm we have just defined!. So if you are looking to (very useful for pedagogical reasons):

$$2^x=10^y \tag{7.1.422}$$

applying a $\log_{10}$ to the previous equation:

$$y=\log_{10} 2^x=x\cdot\log_{10} 2=0.30103x \tag{7.1.423}$$

Therefore we typically we have an order of $2^{10}\approx 10^3$.

Therefore if we remember that the probability of our universe as being as it is, is approximately of the order of $10^{-10^{500}}$ (see page 474) therefore this probability is equivalent to get a given outcome when throwing approximately $10^{10^{1500}}$ coins.

The logarithm in base 10 is used a lot in graphical representations in the scientific perspective when we look at amplitudes variations. For example with Maple™ 4.00b we have for two sine function having respectively for their respective mean the same amplitude variation of 50% visible below that do not highlights necessarily this fact trivially:

```
>plot(10+0.5*10*sin(x),100+100*0.5*sin(x),x=1..10);
```

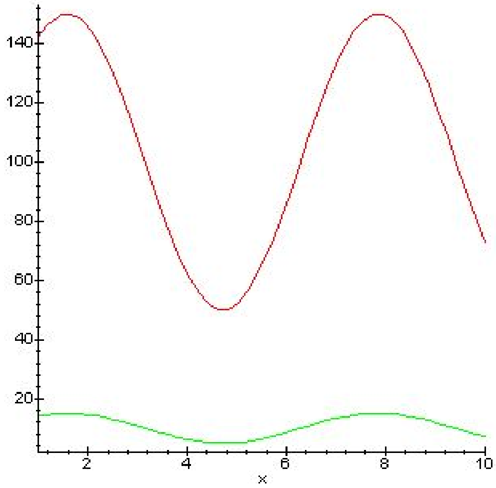


Figure 7.59: Plot with Maple™ 4.00b with two sine functions having same amplitude change compared to their average

While in logarithmic scale, this gives:

```
>with(plots):
>logplot(10+0.5*10*sin(x),100+100*0.5*sin(x),x=1..10);
```

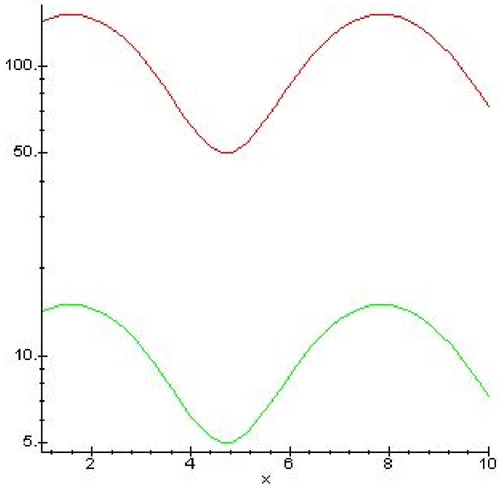

Figure 7.60: Same plot with Maple™ 4.00b but with the y-axis in logarithm (base 10) scale

The logarithmic scale is more well-known for the following kind of plot grid:

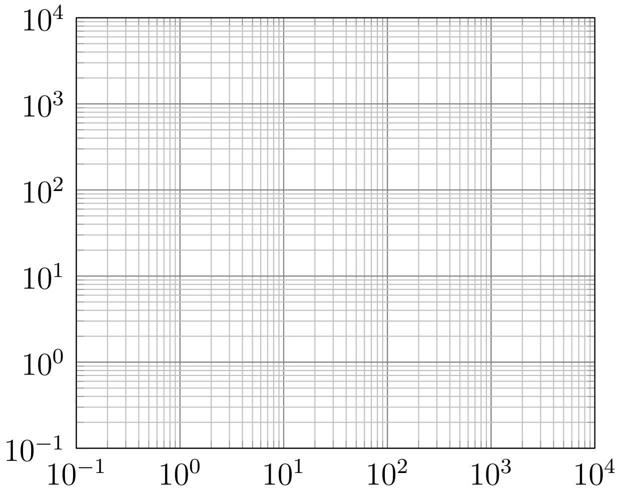

Figure 7.61: **Double logarithmic grid**

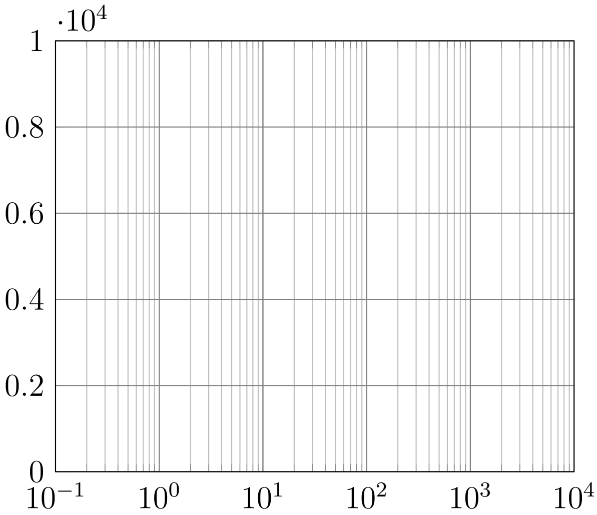

Figure 7.62: **Simple horizontal logarithmic grid**

For the logarithmic function in Eulerian base e it is necessary to calculate:

$$f(x)=\ln(x) \tag{7.1.424}$$

to ask ourselves the following question: at what power $n\in\mathbb{R}$ we must raise the number e to get x?

Formally this consists to solve the equation:

$$e^n=x \tag{7.1.425}$$

with x being known and therefore:

$$\ln(x)=n \tag{7.1.426}$$

Technically, we say that the exponential function (see below for details):

$$\boxed{f(x)=e^x} \tag{7.1.427}$$

is the inverse bijection of the $\ln(x)$ function.

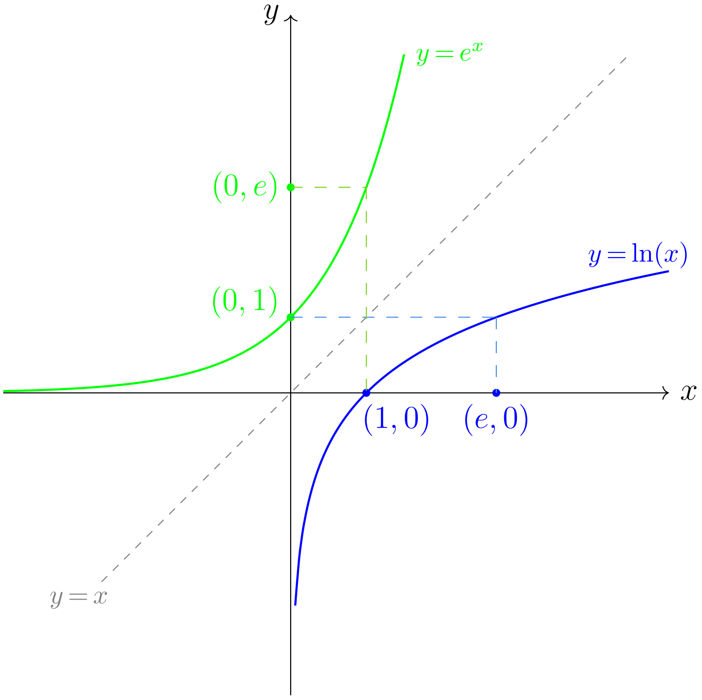

Figure 7.63: Graphical representation of the correspondence between the natural logarithm and the exponential

But what is that "Eulerian" number also named "Euler number"? Why do we find so often in physics and mathematics? Let us first determine the origin of its value:

$$\sqrt[n]{1+n}=(1+n)^{\frac{1}{n}}=\left(1+\frac{1}{\alpha}\right)^{\alpha} \tag{7.1.428}$$

with $\alpha \in \mathbb{N}$ and when $\alpha \rightarrow +\infty$.

Remark

The second term of the equality is typically the type of expression that we find in compound interest in finance (see section Economy page 7557) or in any other type of identical increase factor. And what interests us in this case is when this type of increase tends to infinity.

The interest we have to pose the problem as in this way is that if we do tend $\alpha \rightarrow +\infty$ the function written above tends to e and this function has the special property of being calculable more or less easily for historical reasons using Newton's binomial.

So according to the development of the Newton binomial (see section Calculus page 1364) we can write:

$$\begin{aligned}\left(1+\frac{1}{\alpha}\right)^{\alpha}=&1+\frac{\alpha}{1!}\frac{1}{\alpha}+\frac{\alpha(\alpha-1)}{2!}\frac{1}{\alpha^2}+\frac{\alpha(\alpha-1)(\alpha-2)}{3!}\frac{1}{\alpha^3}\\&+\cdots+\frac{\alpha(\alpha-1)\ldots(\alpha-(\alpha-1))}{\alpha!}\frac{1}{\alpha^{\alpha}}\end{aligned} \tag{7.1.429}$$

This development is similar to the Taylor expansion (see section Sequences and Series page 1696) of some given functions for particular cases of development values (hence the reason why we find this eulerian number in many fields related to applied mathematics as we will see later).

By performing some algebraic transformations that should now be obvious to the reader, we find:

$$\begin{aligned}\left(1+\frac{1}{\alpha}\right)^{\alpha}=1+1+\frac{1}{2!}\left(1-\frac{1}{\alpha}\right)+\frac{1}{3!}\left(1-\frac{1}{\alpha}\right)\left(1-\frac{2}{\alpha}\right)\\+\cdots+\frac{1}{\alpha!}\left(1-\frac{1}{\alpha}\right)\left(1-\frac{2}{\alpha}\right)\ldots\left(1-\frac{\alpha-1}{\alpha}\right)\end{aligned}\tag{7.1.430}$$

We see in this last equality that the function $\left(1+\frac{1}{\alpha}\right)^{\alpha}$ is increasing when α increases. Indeed, when we move from α to the value $\alpha+1$ each term of this sum increases:

$$\frac{1}{2!}\left(1-\frac{1}{\alpha}\right)<\frac{1}{2!}\left(1-\frac{1}{\alpha+1}\right)\text{, etc.}\tag{7.1.431}$$

Let us prove now that the variable $\left(1+\frac{1}{\alpha}\right)^{\alpha}$ is bounded. By seeing that:

$$\left(1-\frac{1}{\alpha}\right)<1,\;\left(1-\frac{1}{\alpha}\right)\left(1-\frac{2}{\alpha}\right)<1\text{, etc.}\tag{7.1.432}$$

So we get by analogy with the extended expression of Newton binomial determined just previously the following order relation:

$$\left(1-\frac{1}{\alpha}\right)^{\frac{1}{\alpha}}<1+\frac{1}{2!}+\frac{1}{3!}+\cdots+\frac{1}{\alpha!}\tag{7.1.433}$$

On the other hand:

$$\frac{1}{3!}<\frac{2}{2!},\;\frac{1}{4!}<\frac{2}{3!},\;\frac{1}{\alpha!}<\frac{2}{2^{\alpha-1}}\tag{7.1.434}$$

We then can write the inequality:

$$\left(1-\frac{1}{\alpha}\right)^{\frac{1}{\alpha}}<1+\underline{1+\frac{1}{2}+\frac{1}{2^2}+\cdots+\frac{1}{2^{\alpha-1}}}\tag{7.1.435}$$

The underlined terms constitute a geometric sequence of reason $q=1/2$ (see section Sequences and Series page 1656) and whose first term is 1. If follows using the result obtained in the section of Sequences ans Series, that we can write:

$$\left(1+\frac{1}{\alpha}\right)^{\alpha}<1+\left[1+\frac{1}{2}+\frac{1}{2^2}+\cdots+\frac{1}{2^{\alpha-1}}\right]=1+\frac{1-(1/2)^{\alpha}}{1-(1/2)}=1+\left[2-\left(\frac{1}{2}\right)^{\alpha-1}\right]<3\tag{7.1.436}$$

Therefore, we have:

$$2\leq\left(1+\frac{1}{\alpha}\right)^{\alpha}<3\tag{7.1.437}$$

We have therefore proved that the function $\left(1+\frac{1}{\alpha}\right)^{\alpha}$ is bounded.

The limit:

$$\boxed{e=\lim_{\alpha\rightarrow\infty}\left(1+\frac{1}{\alpha}\right)^{\alpha}} \tag{7.1.438}$$

tends to this limited value that is the number e whose value is:

$$e=2.7182818284\ldots \tag{7.1.439}$$

The prior previous relation is also know in the following form after an obvious change of variable:

$$e=\lim_{\alpha\rightarrow 0}(1+\alpha)^{1/\alpha} \tag{7.1.440}$$

Remark

As we have proved it in the section Numbers, this number is irrational.

We can then define the "natural exponential function" (reciprocal of the natural logarithm function) by (for those who want to see a kind of circular proof instead than a definition... see page 2246):

$$\boxed{f(x)=e^x=\lim_{\alpha\rightarrow +\infty}\left(1+\frac{x}{\alpha}\right)^{\alpha}} \tag{7.1.441}$$

also sometimes denoted by:

$$f(x)=\exp(x) \tag{7.1.442}$$

The number e and the function that determines it are very useful. We find them in all areas of mathematics and physics and thus in almost all the chapters of this textbook.

As we have proved it in the section of Differential and Integral Calculus the functions e^x has for remarkable property that its derivative is equal to itself:

$$\frac{\mathrm{d}e^x}{\mathrm{d}x}=e^x \tag{7.1.443}$$

and this is used a lot for the resolution of differential equations in physics and finance.

Logarithms have several properties. Here are the most important one in our point of view (we are referring to a given base X) and that are very useful in physics, electronics, chemistry and so on...

Let us begin. First:

$$\log_X(X^mX^n)=\log_X(X^{m+n})=\log_X(X^m)+\log_X(X^n)=m+n \tag{7.1.444}$$

If we put $X^m=a$ and $X^n=b$ we get:

$$\log_X(a\cdot b)=\log_X(a)+\log_X(b) \tag{7.1.445}$$

If we have the special case when $a=b$ then:

$$\log_X(a\cdot a)=\log_X(a)+\log_X(a)=2\log_X(a) \tag{7.1.446}$$

Now let us try to express:

$$\log_X\left(\frac{a}{b}\right) \tag{7.1.447}$$

in another way. For this we put first:

$$t=\frac{a}{b}\Leftrightarrow a=tb \tag{7.1.448}$$

which leads us to the development:

$$\begin{gathered}\log_X(a)=\log_X(t\cdot b)=\log_X(t)+\log_X(b)\\ \Rightarrow\log_X(t)=\log_X(a)-\log_X(b)=\log_X\left(\frac{a}{b}\right)\end{gathered} \tag{7.1.449}$$

Now let us try to express:

$$\log_X\left(x^{1/n}\right) \tag{7.1.450}$$

with $n\in\mathbb{N}^*$ in another way. For this we put first:

$$t=x^{\frac{1}{n}}\Leftrightarrow x=t^n \tag{7.1.451}$$

which leads us to the development:

$$\log_X(x)=\log_X(t^n)=n\cdot\log_X(t)\Rightarrow\log_X(t)=\log_X\left(x^{\frac{1}{n}}\right)=\frac{1}{n}\log_X(x) \tag{7.1.452}$$

There is also another relation used a lot of time in physics in respect to the change of logarithm basis. The first relation is trivial and follows from the algebraic properties of logarithms:

$$a^x=e^{x\ln(a)}=10^{x\log_{10}(a)}=b^{x\log_b(a)} \tag{7.1.453}$$

the second one:

$$\log_a(u)=\frac{\ln(u)}{\ln(a)}=\frac{\log_{10}(u)}{\log_{10}(a)}=\frac{\log_b(u)}{\log_b(a)} \tag{7.1.454}$$

is a bit less trivial and requires perhaps a proof (we used it for our study of continued fractions in the section Number Theory).

Proof 7.3.2. We first use the equivalent equations (of the first relation above):

$$w=\log_a(u)\quad\text{and}\quad a^w=u \tag{7.1.455}$$

and we proceed as follows:

$$\begin{gathered}a^w=u\\ \log_b(a^w)=\log_b(u)\\ w\cdot\log_b(a)=\log_b(u)\end{gathered} \tag{7.1.456}$$

What finally brings us to:

$$w=\frac{\log_b(u)}{\log_b(a)}=\log_a(u) \tag{7.1.457}$$

■ Q.E.D.

7.1.4 Convolutions

A convolution is a mathematical operation on two functions to produce a third function, that is typically viewed as a modified version of one of the original functions, giving the integral of the point-wise multiplication of the two functions as a function of the amount that one of the original functions is translated.

There are different type of convolutions and as always, we will focus in this textbook only on the one that are actually used in other sections of this textbook.

7.1.4.1 Continuous and Discrete Linear Convolution Product

Definition (#7.1.281): The "continuous convolution" of two continuous signals $x(t)$ and $h(t)$ is defined as:

$$\boxed{y(t)=h(t)*x(t)\triangleq\int\limits_{-\infty}^{+\infty}x(\tau)h(t-\tau)\mathrm{d}\tau} \tag{7.1.458}$$

Remark

The convolution is also sometimes denoted with different symbols:

$$y(t)=h(t)\star x(t)\triangleq\int\limits_{-\infty}^{+\infty}x(\tau)h(t-\tau)\mathrm{d}\tau \tag{7.1.459}$$

or:

$$y(t)=h(t)\circledast x(t)\triangleq\int\limits_{-\infty}^{+\infty}x(\tau)h(t-\tau)\mathrm{d}\tau \tag{7.1.460}$$

We will now prove some properties of the convolution by focusing only on those use in the other sections of this textbook!

P1. Convolution is commutative:

$$x(t)*h(t)=h(t)*x(t) \tag{7.1.461}$$

Proof 7.3.3. By making the change of variable $\lambda=t-\tau$, in one form of the definition of convolution:

$$y(t)=h(t)*x(t)\triangleq\int\limits_{-\infty}^{+\infty}x(\tau)h(t-\tau)\mathrm{d}\tau \tag{7.1.462}$$

it becomes:

$$x(t)*h(t)=\int\limits_{-\infty}^{+\infty} x(t-\lambda)h(\lambda)\mathrm{d}\lambda=\int\limits_{-\infty}^{+\infty} h(\lambda)x(t-\lambda)\mathrm{d}\lambda=h(t)*x(t) \tag{7.1.463}$$

proving that convolution is commutative.

■ Q.E.D.

P2. Convolution is associative:

$$(f*g)(t)=\int\limits_{0}^{t} f(s)g(t-s)\mathrm{d}s \tag{7.1.464}$$

Proof 7.3.4. The proof is easier to understand if we consider a limited integral (but you can change the bounds to the infinity one and you will fall back on the general result):

$$\begin{aligned}((f*g)*h)(t)&=\int_0^t (f*g)(s)h(t-s)\mathrm{d}s\\&=\int_{s=0}^t\left(\int_{u=0}^s f(u)g(s-u)\mathrm{d}u\right)h(t-s)\mathrm{d}s\\&=\int_{s=0}^t\int_{u=0}^s f(u)g(s-u)h(t-s)\mathrm{d}u\mathrm{d}s\\&=\int_{u=0}^t\int_{s=u}^t f(u)g(s-u)h(t-s)\mathrm{d}s\mathrm{d}u\\&=\int_{u=0}^t\int_{s=0}^{t-u} f(u)g(s)h(t-s-u)\mathrm{d}s\mathrm{d}u\\&=\int_{u=0}^t f(u)\left(\int_{s=0}^{t-u} g(s)h(t-u-s)\mathrm{d}s\right)\mathrm{d}u\\&=\int_{u=0}^t f(u)(g\star h)(t-u)\mathrm{d}u\\&=(f*(g*h))(t)\end{aligned} \tag{7.1.465}$$

The proof may not be obvious for many readers. So we recommend to see the equivalent proof for the discrete version further below.

■ Q.E.D.

P3. Convolution is distributive:

$$x(t)*[h_1(t)+h_2(t)]=x(t)*h_1(t)+x(t)*h_2(t) \tag{7.1.466}$$

Proof 7.3.5.

$$\begin{aligned}x(t)*[h_1(t)+h_2(t)]&=\int\limits_{-\infty}^{+\infty} x(t)\left[h_1(t-\tau)+h_2(t-\tau)\right]\mathrm{d}\tau=\int\limits_{-\infty}^{+\infty} x(t)h_1(t-\tau)\mathrm{d}\tau+\int\limits_{-\infty}^{+\infty} x(t)h_1(t-\tau)\mathrm{d}\tau\\&=x(t)*h_1(t)+x(t)*h_2(t)\end{aligned} \tag{7.1.467}$$

■ Q.E.D.

P4. Relation with differentiation:

$$(f*g)'=f'*g=f*g' \tag{7.1.468}$$

Proof 7.3.6.

$$\begin{gathered}(f*g)'=\frac{\mathrm{d}}{\mathrm{d}t}\int\limits_{-\infty}^{+\infty}f(\tau)g(t-\tau)\mathrm{d}\tau=\int_{-\infty}^{+\infty}f(\tau)\frac{\partial}{\partial t}g(t-\tau)\mathrm{d}\tau=\int\limits_{-\infty}^{+\infty}f(\tau)\frac{\partial}{\partial t}g(t-\tau)\mathrm{d}\tau\\=\int\limits_{-\infty}^{+\infty}f(\tau)g'(t-\tau)\mathrm{d}\tau=f*g'=\int\limits_{-\infty}^{+\infty}f(\tau)g'(t-\tau)\mathrm{d}\tau=f*g'\end{gathered} \tag{7.1.469}$$

■ Q.E.D.

We will assume as obvious that these properties also apply to the discrete convolution that we will introduce now!

Typically, $y(t)$ is the output of a system characterized by its impulse response function $h(t)$ with input $x(t)$.

Definition (#7.1.282): The "discrete convolution" of two discrete signals $x[n]$ and $h[n]$ is defined as:

$$\boxed{y[n]=\sum_{m=-\infty}^{+\infty}x[n-m]\,h[m]=\sum_{m=-\infty}^{+\infty}h[n-m]\,x[m]} \tag{7.1.470}$$

If $h[m]$ is finite, e.g.:

$$h[m]=\begin{cases}h[m] & |m|\leq k\\ 0 & |m|>k\end{cases} \tag{7.1.471}$$

the convolution becomes:

$$y[n]=\sum_{m=-k}^{k}x[n-m]\,h[m] \tag{7.1.472}$$

If the system in question were a causal system in time domain:

$$h(n)=h[n]u[n],\quad \text{i.e.,}\quad h[n]=0\quad \text{if } n<0 \tag{7.1.473}$$

the above would become:

$$y[n]=\sum_{m=0}^{k}x[n-m]\,h[m] \tag{7.1.474}$$

This is also written:

$$\boxed{(f*g)[n]=\sum_{k=0}^{n}f[k]g[n-k]} \tag{7.1.475}$$

✍**Examples:**

E1. Consider:

$$f[n]=3\delta(n)+2\delta(n-1)+1\delta(n-2) \tag{7.1.476}$$

$$g[n]=2\delta(n)+1\delta(n-1)+3\delta(n-2) \tag{7.1.477}$$

We get visually (it's not obvious!):

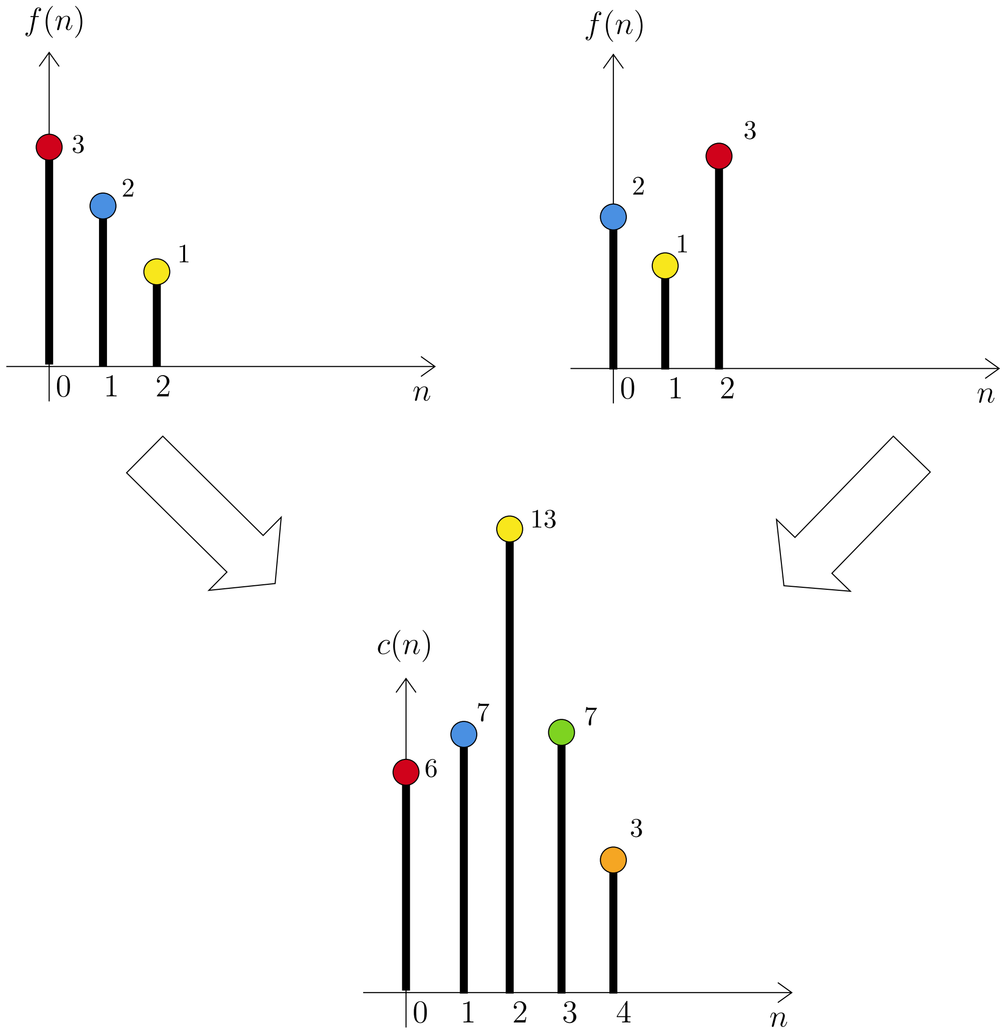

Figure 7.64: Discrete convolution example

The details steps are given by first considering that:

$$(f*g)[n]=c[n]=\sum_{m=0}^{2}g[n-m]f[m] \tag{7.1.478}$$

And we have for recall:

$$\begin{matrix} f(m=0)=3 & g(k=0)=2 \\ f(m=1)=2 & g(k=1)=1 \\ f(m=2)=1 & g(k=2)=3 \end{matrix} \tag{7.1.479}$$

And in tabular form:

n:	0	1	2	3	4
$m=0$	$2\cdot 3=6$	$1\cdot 3=3$	$3\cdot 3=9$	0	0
$m=1$	0	$2\cdot 2=4$	$1\cdot 2=2$	$3\cdot 2=6$	0
$m=2$	0	0	$2\cdot 1=2$	$1\cdot 1=1$	$3\cdot 1=3$
$c[n]$	6	7	13	7	3

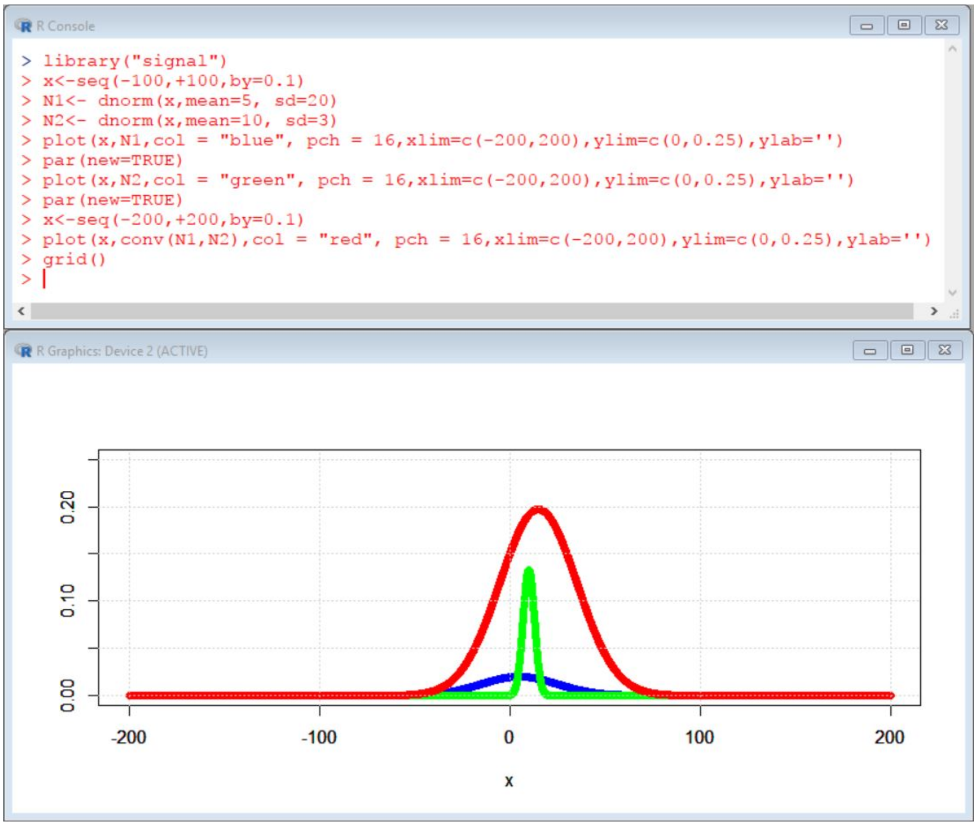
The $c[n>4]$ being all equal to zero.

The final result will then be written:

$$c[n]=6\delta(n)+7\delta(n-1)+13\delta(n-2)+7\delta(n-3)+3\delta(n-4) \tag{7.1.480}$$

Such a calculations can obviously be done very simply with softwares like R for example (see the corresponding companion book).

E2. A well known example is the convolution of two gaussians (see section Statistics page 709) that also result in a... gaussian. And obviously the discrete version of the convolution also give a gaussian as illustrated below with R (see the corresponding companion book for more details):



```
> library("signal")
> x<-seq(-100,+100,by=0.1)
> N1<- dnorm(x,mean=5, sd=20)
> N2<- dnorm(x,mean=10, sd=3)
> plot(x,N1,col = "blue", pch = 16,xlim=c(-200,200),ylim=c(0,0.25),ylab='')
> par(new=TRUE)
> plot(x,N2,col = "green", pch = 16,xlim=c(-200,200),ylim=c(0,0.25),ylab='')
> par(new=TRUE)
> x<-seq(-200,+200,by=0.1)
> plot(x,conv(N1,N2),col = "red", pch = 16,xlim=c(-200,200),ylim=c(0,0.25),ylab='')
> grid()
> |
```

where we have as the reader have noticed above, the following convolution $\mathcal{N}(5,20)*\mathcal{N}(10,3)$ and we see obviously that the result gives a gaussian of $\mathcal{N}(5+10=15,\sqrt{20^2+3^2}=15)$.

Let us now prove that the discrete convolution is also associative for the discrete convolution (as promised earlier!):

Proof 7.3.7.

$$\begin{aligned}((f*g)\star h)(n)&=\sum_{k=0}^{n}(f\star g)[k]h[n-k]\\&=\sum_{k=0}^{n}\sum_{l=0}^{k}f[l]g[k-l]h[n-k]\\&=\sum_{l=0}^{n}\sum_{k=l}^{n}f[l]g[k-l]h[n-k]\\&=\sum_{l=0}^{n}\sum_{k=0}^{n-l}f[l]g[k]h[n-k-l]\\&=\sum_{l=0}^{n}f[l](g*h)[n-l]\\&=(f*(g*h))(n)\end{aligned} \tag{7.1.481}$$

■ Q.E.D.

However, in image processing, we often consider convolution in spatial domain where causality does not apply.

If $h[m]=h[-m]$ is symmetric (almost always true in image processing), then replacing m by $-m$ we get:

$$y[n]=\sum_{m=-k}^{k}x[n+m]\,h[-m]=\sum_{m=-k}^{k}x[n+m]\,h[m] \tag{7.1.482}$$

We see now that the convolution is similar to the *correlation* of two functions!

If the input $x[m]$ is finite (always true in reality), i.e.:

$$x[m]=\begin{cases}x[m] & 0\leq m<N\\ 0 & \text{otherwise}\end{cases} \tag{7.1.483}$$

its index $n+m$ in the convolution has to satisfy the following for x to be in the valid non-zero range:

$$0\leq n+m\leq N-1 \tag{7.1.484}$$

or correspondingly, the index n of the output $y[n]$ has to satisfy:

$$-m\leq n\leq N-m-1 \tag{7.1.485}$$

When the variable index m in the convolution is equal to k, the index of output $y[n]$ reaches its lower bound $n=-k$; when $m=-k$, the index of $y[n]$ reaches its upper bound $n=N+k-1$. In other words, there are $N+2k$ valid (non-zero) elements in the output:

$$y[n],\quad(-k\leq n\leq N+k-1) \tag{7.1.486}$$

Assume the size of the input signal $x[n]$ is N $(n=0,\cdots,n=N-1)$ and the size of h is $M=2k+1$ (usually an odd number), then the size of the resulting convolution $y=x*h$ is $N+M-1=N+2k$. However, as it is usually desirable for the output y to have the same size as the input x, we can drop k components at each end of y. When the size of h is even,we can drop k components at one end and $k-1$ from the other of y.

7.1.4.2 Matrix Convolution

In image processing, all of the discussions above for one-dimensional convolution are generalized into two dimensions!

Definition(#7.1.283): "Matrix convolution" is the treatment of a matrix by another one which is named the "kernel". Most of the time, the convolution matrix filter uses a first matrix which is the image to be treated. The image is a bi-dimensional collection of pixels in rectangular coordinates. The used kernel h of always odd $k\times k$ dimensions depends on the effect you want!

By construction, we have:

$$\boxed{C[m,n]=\text{Image}*\text{Kernel}=f*h[m,n]=\sum_{i=-\frac{k-1}{2}}^{+\frac{k-1}{2}}\sum_{j=-\frac{k-1}{2}}^{+\frac{k-1}{2}} h\left(i+\frac{k+1}{2},j+\frac{k+1}{2}\right)f(m+i,n+j)} \tag{7.1.487}$$

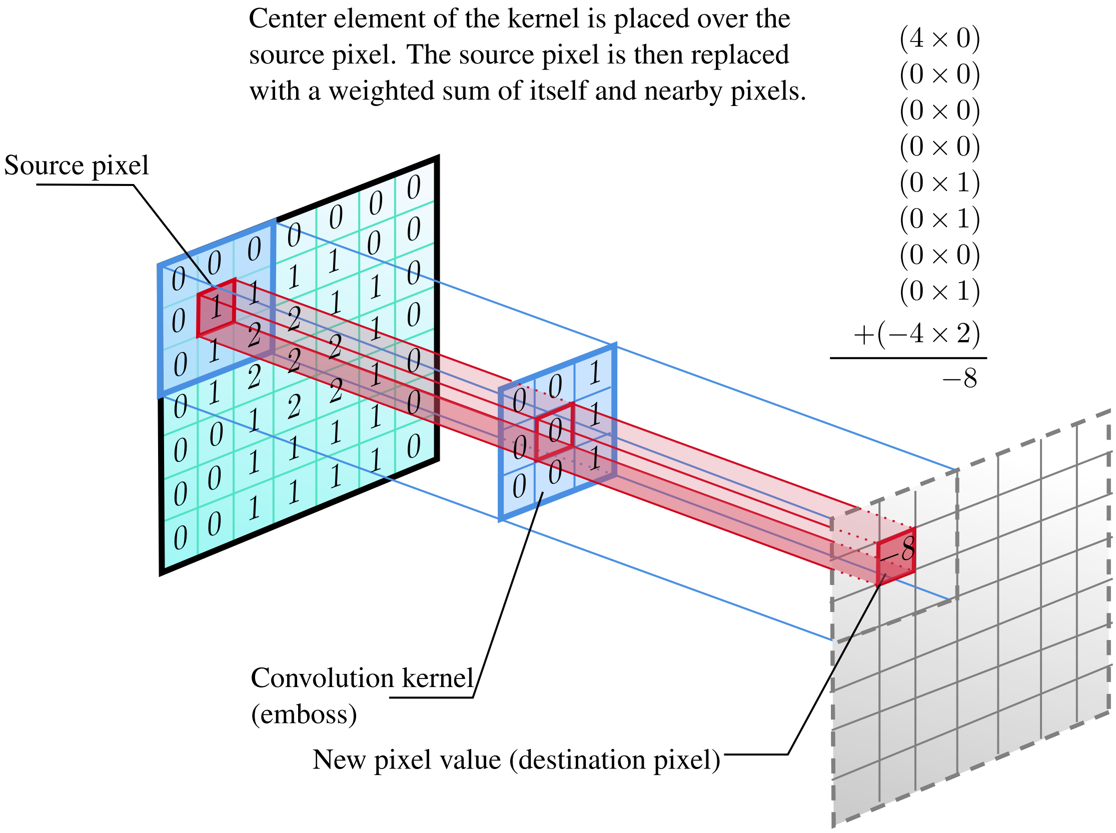
For example, if we have the following matrices:

$$f=\begin{bmatrix}0&0&0&0&0&0&0\\0&1&1&1&1&0&0\\0&1&2&2&1&1&0\\0&1&2&2&2&1&0\\0&0&1&2&2&1&0\\0&0&1&1&1&1&0\\0&0&1&1&1&1&0\end{bmatrix}\qquad h=\begin{bmatrix}-4&0&0\\0&0&0\\0&0&4\end{bmatrix} \tag{7.1.488}$$

Then (don't forget that the columns and row of the kernel matrix are flipped!):

$$\begin{aligned}C[2,2]=&\begin{bmatrix}0&0&0&0&0&0&0\\0&1&1&1&1&0&0\\0&1&2&2&1&1&0\\0&1&2&2&2&1&0\\0&0&1&2&2&1&0\\0&0&1&1&1&1&0\\0&0&1&1&1&1&0\end{bmatrix}*h[2,2]=\sum_{i=-1}^{+1}\sum_{j=-1}^{+1}h(i+2,j+2)f(2+i,2+j)\\&=f(1,1)h(1,1)+f(1,2)h(1,2)+f(1,3)h(1,3)+f(2,1)h(2,1)+f(2,2)h(2,2)\\&+f(2,3)h(2,3)+f(1,3)h(1,3)+f(2,3)h(2,3)+f(3,3)h(3,3)\\&=0\cdot 4+0\cdot 0+0\cdot 0+0\cdot 0+1\cdot 0+1\cdot 0+0\cdot 0+1\cdot 0+2\cdot(-4)=-8\end{aligned} \tag{7.1.489}$$

That can be illustrated as following (h has already been double-flipped in the figure below):

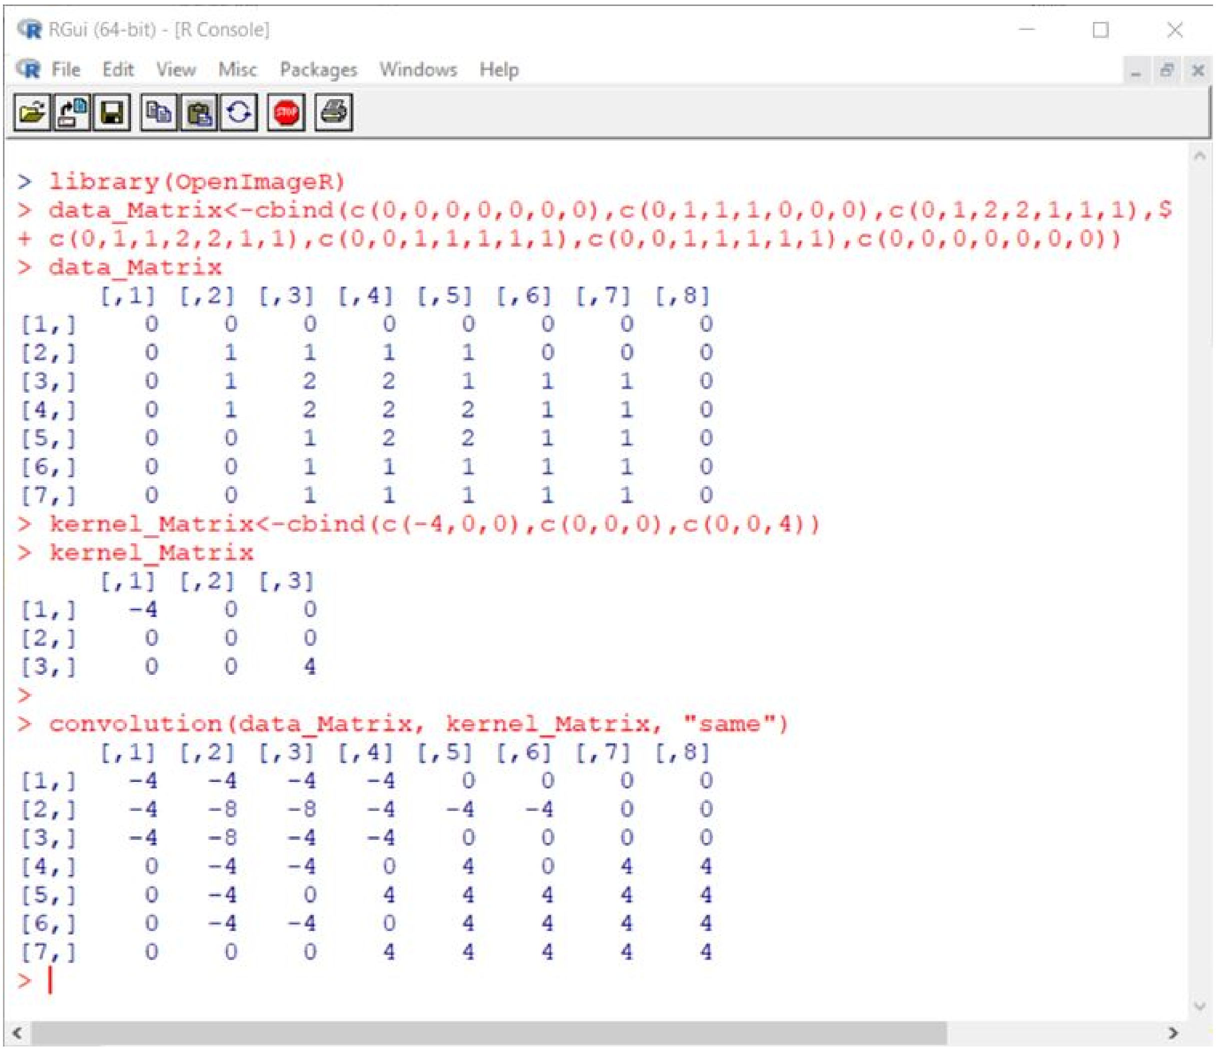


Center element of the kernel is placed over the source pixel. The source pixel is then replaced with a weighted sum of itself and nearby pixels.

(4 × 0)
(0 × 0)
(0 × 0)
(0 × 0)
(0 × 1)
(0 × 1)
(0 × 0)
(0 × 1)
+(−4 × 2)
−8
Source pixel
Convolution kernel (emboss)
New pixel value (destination pixel)

Figure 7.65: **Matrix Convolution**

The full example can be run and reproduced with a free software like `R`:



RGui (64-bit) - [R Console]
File Edit View Misc Packages Windows Help

```

> 
```

Or for people who may prefer a slow implementation in C++:

Listing 7.1: **C++ for matrix convolution**

```cpp
// find center position of kernel (half of kernel size)
kCenterX = kCols / 2;
kCenterY = kRows / 2;

for(i=0; i < rows; ++i)              // rows
{
    for(j=0; j < cols; ++j)          // columns
    {
        for(m=0; m < kRows; ++m)     // kernel rows
        {
            mm = kRows - 1 - m;      // row index of flipped kernel

            for(n=0; n < kCols; ++n) // kernel columns
            {
                nn = kCols - 1 - n;  // column index of flipped kernel

                // index of input signal, used for checking
```

```
                   boundary
                ii = i + (kCenterY - mm);
                jj = j + (kCenterX - nn);

                // ignore input samples which are out of bound
                if( ii >= 0 && ii < rows && jj >= 0 && jj < cols )
                    out[i][j] += in[ii][jj] * kernel[mm][nn];
            }
        }
    }
}
```

7.1.5 Integral Transforms

An "integral transform" is an operator that maps functions from one space to another. Formally:

$$\boxed{\mathcal{T}(f(x))=\int\limits_{-\infty}^{+\infty}K(x,y)f(y)\mathrm{d}y} \tag{7.1.490}$$

Now the practical motivation for an integral transform is to reduce the complexity of the problem i.e the mathematical operations will be much easier to handle in the image space (typically the resolution of differential equations!).

However, as much as it is fun to do work in the image space, one has to be able to interpret the results in the original space. To do so requires the study of the operator K. Usually one knows a priori the nature of the function f by the nature of the problem one is dealing. Hence the study of integral transforms is the study of the operator $\mathcal{T}$. Two properties come very easily:

$$\mathcal{T}(f+g)=\mathcal{T}(f)+\mathcal{T}(g) \tag{7.1.491}$$

$$\mathcal{T}(cf)=c\mathcal{T}(f) \tag{7.1.492}$$

To ensure invertibility, one has to show that the kernel space only contains the null function.

The Fourier and Laplace transforms are for example continuous (integral) transforms of continuous functions (even if there exist a discrete version of the Fourier transform!).

The Laplace transform maps a function $f(t)$ to a function $\mathcal{F}(s)$ of the complex variable s, where:

$$s=\sigma+\mathrm{i}\omega \tag{7.1.493}$$

Since the derivative:

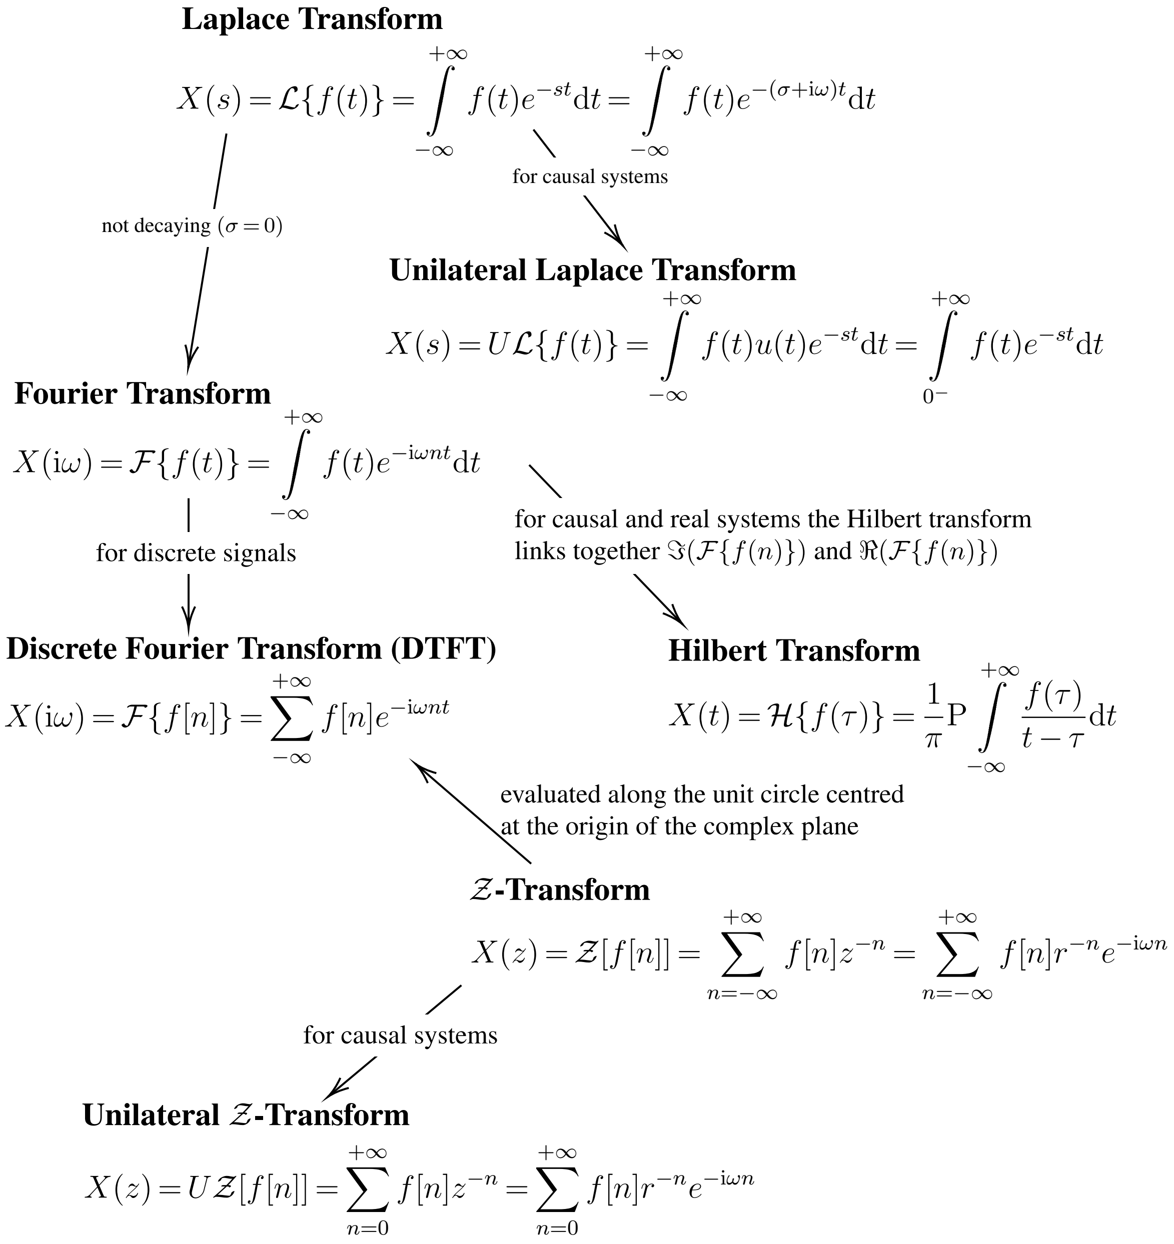
$$f'(t)=\frac{\mathrm{d}f(t)}{\mathrm{d}t} \tag{7.1.494}$$

maps to $s\mathcal{F}(s)$, the Laplace transform $\mathcal{L}$ of a linear differential equation is an algebraic equation. Thus, the Laplace transform is useful for, among other things, solving linear differential equations.

If we set the real part of the complex variable s to zero, $\sigma=0$, the result is the Fourier transform $\mathcal{F}(\mathrm{i}\omega)$ which is essentially the frequency domain representation of $f(t)$ (note that this is true only if for that value of σ the formula to obtain the Laplace transform of $f(t)$ exists, i.e., it does not go to infinity).

The $\mathcal{Z}$-transform is essentially a discrete version of the Laplace transform and, thus, can be useful in solving difference equations, the discrete version of differential equations. The $\mathcal{Z}$-transform maps a sequence $f[n]$ to a continuous function $F(z)$ of the complex variable $z=re^{\mathrm{i}\Omega}$.

If we set the magnitude of z to unity, $r=1$, the result is the Discrete Time Fourier Transform (DTFT) $\mathcal{F}(\mathrm{i}\Omega)$ which is essentially the frequency domain representation of $f[n]$.



Laplace Transform

$$X(s)=\mathcal{L}\{f(t)\}=\int\limits_{-\infty}^{+\infty} f(t)e^{-st}\mathrm{d}t=\int\limits_{-\infty}^{+\infty} f(t)e^{-(\sigma+\mathrm{i}\omega)t}\mathrm{d}t$$

Unilateral Laplace Transform

$$X(s)=U\mathcal{L}\{f(t)\}=\int\limits_{-\infty}^{+\infty} f(t)u(t)e^{-st}\mathrm{d}t=\int\limits_{0^-}^{+\infty} f(t)e^{-st}\mathrm{d}t$$

Fourier Transform

$$X(\mathrm{i}\omega)=\mathcal{F}\{f(t)\}=\int\limits_{-\infty}^{+\infty} f(t)e^{-\mathrm{i}\omega nt}\mathrm{d}t$$

Discrete Fourier Transform (DTFT)

$$X(\mathrm{i}\omega)=\mathcal{F}\{f[n]\}=\sum_{-\infty}^{+\infty} f[n]e^{-\mathrm{i}\omega nt}$$

Hilbert Transform

$$X(t)=\mathcal{H}\{f(\tau)\}=\frac{1}{\pi}\mathrm{P}\int\limits_{-\infty}^{+\infty}\frac{f(\tau)}{t-\tau}\mathrm{d}t$$

$\mathcal{Z}$-Transform

$$X(z)=\mathcal{Z}[f[n]]=\sum_{n=-\infty}^{+\infty} f[n]z^{-n}=\sum_{n=-\infty}^{+\infty} f[n]r^{-n}e^{-\mathrm{i}\omega n}$$

Unilateral $\mathcal{Z}$-Transform

$$X(z)=U\mathcal{Z}[f[n]]=\sum_{n=0}^{+\infty} f[n]z^{-n}=\sum_{n=0}^{+\infty} f[n]r^{-n}e^{-\mathrm{i}\omega n}$$

for causal systems
not decaying ($\sigma=0$)
for discrete signals
for causal and real systems the Hilbert transform links together $\Im(\mathcal{F}\{f(n)\})$ and $\Re(\mathcal{F}\{f(n)\})$
evaluated along the unit circle centred at the origin of the complex plane
for causal systems

Figure 7.66: **Most common types of integral transforms with harmonized notation**

Remarks

R1. The three integral transformations mentioned above (Fourier, Laplace, $\mathcal{Z}$) are only a sample of what exists in practice. Let us also mention the Hartley transform, the Mellin transform, the Weierstrass transform, the Hankel transform (Fourier-Bessel), the Abel transform, the Hilbert transform, the Gauss-Weierstrass transform, etc.

R2. For information we will calculate cases and prove properties of the Fourier, Laplace, $\mathcal{Z}$ and Hilbert transforms only used in concrete applications in the industry and mainly useful in other chapters of this textbook! Indeed a rather general presentation would require a few hundred pages and it is not the objective of this textbook, as you already know it, to prove mathematical properties not associated with concrete cases.

7.1.5.1 Fourier Transform

So we have already introduced Fourier Transforms in the section of Sequences and Series (page 1758), we will come back here more in details on this topic in (we wish) are more structured way...

7.1.5.1.1 Continuous Time Fourier Transform

The Fourier expansion coefficient $X[k]$ of a continuous periodic signal $x_T(t)=x_T(t+T)$ is:

$$X[k]=\frac{1}{T}\int_T x_T(t)e^{-\mathrm{i}k\omega_0 t}\mathrm{d}t \quad (k=0,\pm 1,\pm 2,\cdots) \tag{7.1.495}$$

and the Fourier expansion of the signal is:

$$x_T(t)=\sum_{k=-\infty}^{+\infty} X[k]e^{\mathrm{i}k\omega_0 t} \tag{7.1.496}$$

which can also be written as:

$$x_T(t)=\frac{1}{T}\sum_{k=-\infty}^{+\infty}(TX[k])e^{\mathrm{i}k\omega_0 t}=\frac{\omega_0}{2\pi}\sum_{k=-\infty}^{+\infty}X(k\omega_0)e^{\mathrm{i}k\omega_0 t} \quad (a) \tag{7.1.497}$$

where $X(k\omega_0)$ is defined as:

$$X(k\omega_0)\triangleq T\,X[k]=\int_T x_T(t)e^{-\mathrm{i}k\omega_0 t}\mathrm{d}t \quad (b) \tag{7.1.498}$$

When the period of $x_T(t)$ approaches infinity $T\rightarrow+\infty$, the periodic signal $x_T(t)$ becomes a non-periodic signal $x(t)$ and the following will result:

- Interval between two neighbouring frequency components becomes zero:

$$T\rightarrow+\infty\Longrightarrow\omega_0=\frac{2\pi}{T}\rightarrow 0 \tag{7.1.499}$$

- Discrete frequency becomes continuous frequency:

$$k\omega_0|_{\omega_0\rightarrow 0}\Longrightarrow\omega \tag{7.1.500}$$

- Summation of the Fourier expansion becomes an integral:

$$x(t)\triangleq\lim_{T\rightarrow+\infty}x_T(t)=\lim_{\omega_0\rightarrow 0}\frac{1}{2\pi}\sum_{k=-\infty}^{+\infty}X(k\omega_0)e^{\mathrm{i}k\omega_0 t}\omega_0=\frac{1}{2\pi}\int_{-\infty}^{+\infty}X(\omega)e^{\mathrm{i}\omega t}\mathrm{d}\omega \tag{7.1.501}$$

  the second equal sign is due to the general fact:

$$\lim_{\Delta x\rightarrow 0}\sum_{k=-\infty}^{+\infty}f(k\Delta x)\Delta x=\int_{-\infty}^{+\infty}f(x)\mathrm{d}x \tag{7.1.502}$$

- Time integral over T becomes over the entire time axis:

$$X(\omega)\stackrel{\triangle}{=}\lim_{T\to+\infty}X(k\omega_0)=\lim_{T\to+\infty}\int\limits_T x_T(t)e^{-\mathrm{i}k\omega_0 t}\mathrm{d}t=\int\limits_{-\infty}^{+\infty}x(t)e^{-\mathrm{i}\omega t}\mathrm{d}t \qquad (7.1.503)$$

In summary, when the signal is non-periodic $x(t)=\lim_{T\to+\infty}x_T(t)$, the Fourier expansion becomes Fourier transform. The forward transform (analysis) is:

$$X(\omega)=\int\limits_{-\infty}^{+\infty}x(t)e^{-\mathrm{i}\omega t}\mathrm{d}t \quad \text{or} \quad X(f)=\int\limits_{-\infty}^{+\infty}x(t)e^{-\mathrm{i}2\pi f t}\mathrm{d}t \qquad (7.1.504)$$

and the inverse transform (synthesis) is:

$$x(t)=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}X(\omega)e^{\mathrm{i}\omega t}\mathrm{d}\omega=\int\limits_{-\infty}^{+\infty}X(f)e^{\mathrm{i}2\pi f t}\mathrm{d}f \qquad (7.1.505)$$

Comparing Fourier coefficient of a periodic signal $x_T(t)$ with Fourier spectrum of a non-periodic signal $x(t)$:

$$X[k]=\frac{1}{T}\int\limits_T x_T(t)e^{-\mathrm{i}k\omega_0 t}\mathrm{d}t,\quad X(\omega)=\int\limits_{-\infty}^{+\infty}x(t)e^{-\mathrm{i}\omega t}\mathrm{d}t \qquad (7.1.506)$$

The spectrum of a time signal can be denoted by $X(\omega)$ or $X(f)$ to emphasize the fact that the spectrum represents how the energy contained in the signal is distributed as a function of frequency ω or f. Moreover, if $X(f)$ is used, the factor $1/2\pi$ in front of the inverse transform is dropped so that the transform pair takes a more symmetric form. On the other hand, as Fourier transform can be considered as a special case of Laplace transform when the real part σ of the complex argument $s=\sigma+\mathrm{i}\omega=\mathrm{i}\omega$ is zero:

$$X(s)|_{s=\mathrm{i}\omega}=\int\limits_{-\infty}^{+\infty}x(t)e^{-st}\mathrm{d}t|_{s=\mathrm{i}\omega}=\int\limits_{-\infty}^{+\infty}x(t)e^{-\mathrm{i}\omega t}\mathrm{d}t=X(\mathrm{i}\omega) \qquad (7.1.507)$$

It is also natural to denote the spectrum of $x(t)$ by $X(\mathrm{i}\omega)$.

Ok this done let us see now some important example for physics (especially quantum physics) and signal processing!

✍**Examples:**

E1. Consider the unit impulse function (Dirac function):

$$x(t-a)=\delta(t-a) \qquad (7.1.508)$$

Therefore:

$$X(\mathrm{i}\omega)=\int_{-\infty}^{+\infty}\delta(t-a)e^{-\mathrm{i}\omega t}\mathrm{d}t=e^{-\mathrm{i}\omega a} \tag{7.1.509}$$

and if $a=0$ we have then:

$$X(\mathrm{i}\omega)=\int_{-\infty}^{+\infty}\delta(t)e^{-\mathrm{i}\omega t}\mathrm{d}t=1 \tag{7.1.510}$$

E2. If the spectrum of a signal $x(t)$ is a delta function in frequency domain $X(\mathrm{i}\omega)=2\pi\,\delta(\omega)$, the signal can be found to be:

$$x(t)=\mathcal{F}^{-1}(X(\mathrm{i}\omega))=\frac{1}{2\pi}\int_{-\infty}^{+\infty}2\pi\,\delta(\omega)e^{\mathrm{i}\omega t}\mathrm{d}\omega=e^{0}=1 \tag{7.1.511}$$

i.e.:

$$\mathcal{F}(x(t))=\int_{-\infty}^{+\infty}e^{-\mathrm{i}\omega t}\mathrm{d}t=2\pi\,\delta(\omega) \tag{7.1.512}$$

E3. We consider:

$$x(t)=\begin{cases}1 & |t|<a\\ 0 & \text{else}\end{cases} \tag{7.1.513}$$

The spectrum is:

$$X(\mathrm{i}\omega)=\int_{-a}^{a}e^{-\mathrm{i}\omega t}\mathrm{d}t=\frac{1}{-\mathrm{i}\omega}e^{-\mathrm{i}\omega t}|_{-a}^{a}=\frac{2}{\omega}\sin(a\omega) \tag{7.1.514}$$

This is the sinc function with a parameter a.

Note that the height of the main peak is $2a$ and it gets taller and narrower as a gets larger.

Also note:

$$\int_{-\infty}^{+\infty}X(\mathrm{i}\omega)\mathrm{d}\omega=2\int_{-\infty}^{+\infty}\frac{\sin(a\omega)}{\omega}\mathrm{d}\omega=2\pi \tag{7.1.515}$$

When a approaches infinity, $x(t)=1$ for all t, and the spectrum becomes:

$$X(\mathrm{i}\omega)=\int_{-\infty}^{+\infty}e^{-\mathrm{i}\omega t}\mathrm{d}t=\lim_{a\to+\infty}\left[\frac{2}{\omega}\sin(a\omega)\right]=2\pi\delta(\omega)=\delta(f) \tag{7.1.516}$$

Recall that the Fourier coefficient of $x(t)=1$ is:

$$X[k]=\delta[k]=\begin{cases}1 & k=0\\ 0 & \text{else}\end{cases} \tag{7.1.517}$$

which represents the energy contained in the signal at $k=0$ (DC component at zero frequency), and the spectrum $X(\mathrm{i}\omega)=X[k]/\omega$ is the energy density or distribution which is infinity at zero frequency.

The integral in the above transform is an important formula to be used frequently later:

$$\int\limits_{-\infty}^{+\infty} e^{-\mathrm{i}\omega t}\mathrm{d}t=2\pi\delta(\omega)\quad\text{or}\quad\int\limits_{-\infty}^{+\infty} e^{-\mathrm{i}2\pi ft}\mathrm{d}t=\delta(f) \tag{7.1.518}$$

which can also be written as:

$$\int\limits_{-\infty}^{+\infty} e^{-\mathrm{i}\omega t}\mathrm{d}t=\int\limits_{-\infty}^{+\infty}[\cos(\omega t)+\mathrm{i}\,\sin(-\mathrm{i}\omega t)]\mathrm{d}t=\int\limits_{-\infty}^{+\infty}\cos(\omega t)\mathrm{d}t=\delta(f) \tag{7.1.519}$$

Switching t and f in the equation above, we also have:

$$\int\limits_{-\infty}^{+\infty} e^{-\mathrm{i}2\pi ft}\mathrm{d}f=\int\limits_{-\infty}^{+\infty}\cos(2\pi ft)\mathrm{d}f=\delta(t) \tag{7.1.520}$$

representing a superposition of an infinite number of cosine functions of all frequencies, which cancel each other any where along the time axis except at $t=0$ where they add up to infinity, an impulse.

E3. Let us now consider:

$$x(t)=\cos(\omega_0 t)=\frac{1}{2}[e^{\mathrm{i}\omega_0 t}+e^{-\mathrm{i}\omega_0 t}] \tag{7.1.521}$$

The spectrum of the cosine function is:

$$\begin{aligned}X(\mathrm{i}\omega)&=\int\limits_{-\infty}^{+\infty}x(t)e^{-\mathrm{i}\omega t}\mathrm{d}t=\frac{1}{2}\int\limits_{-\infty}^{+\infty}[e^{\mathrm{i}\omega_0 t}+e^{-\mathrm{i}\omega_0 t}]e^{-\mathrm{i}\omega t}\mathrm{d}t\\&=\pi[\delta(\omega-\omega_0)+\delta(\omega+\omega_0)]\end{aligned} \tag{7.1.522}$$

The spectrum of the sine function:

$$x(t)=\sin(\omega_0 t)=\frac{1}{2\mathrm{i}}[e^{\mathrm{i}\omega_0 t}-e^{-\mathrm{i}\omega_0 t}] \tag{7.1.523}$$

can be similarly obtained to be:

$$X(\mathrm{i}\omega)=\frac{\pi}{\mathrm{i}}[\delta(\omega-\omega_0)-\delta(\omega+\omega_0)]=-\mathrm{i}\pi[\delta(\omega-\omega_0)-\delta(\omega+\omega_0)] \tag{7.1.524}$$

Again, these spectra represent the energy density distribution of the sinusoids, while the corresponding Fourier coefficients:

$$X[k]=\mathcal{F}(\cos(\omega_0 t))=\frac{1}{2}[\delta[k-1]+\delta[k+1]] \tag{7.1.525}$$

and:

$$X[k]=\mathcal{F}(\sin(\omega_0 t))=\frac{1}{2\mathrm{i}}[\delta[k-1]-\delta[k+1]] \tag{7.1.526}$$

represent the energy contained at frequency $\omega=\omega_0$.

7.1.5.1.1.1 Properties of Fourier Transform

The properties of the Fourier transform are summarized below. For some of them already proved in the section of Sequences and Series we will not give the proof. But for others we will do it again!

In the following, we assume $\mathcal{F}(x(t))=X(\mathrm{i}\omega)$ and $\mathcal{F}(y(t))=Y(\mathrm{i}\omega)$.

P1. Linearity:

$$\mathcal{F}(ax(t)+by(t))=a\mathcal{F}(x(t))+b\mathcal{F}(y(t)) \tag{7.1.527}$$

P2. Time shift:

$$\mathcal{F}(x(t\pm t_0))=X(\mathrm{i}\omega)e^{\pm\mathrm{i}\omega t_0} \tag{7.1.528}$$

Proof 7.3.8. Let $t'=t\pm t_0$, i.e., $t=t'\mp t_0$, we have:

$$\begin{aligned}\mathcal{F}(x(t\pm t_0)) &= \int_{-\infty}^{+\infty} x(t\pm t_0)e^{-\mathrm{i}\omega t}\mathrm{d}t=\int_{-\infty}^{+\infty} x(t')e^{-\mathrm{i}\omega(t'\mp t_0)}\mathrm{d}t'\\ &= e^{\pm\mathrm{i}\omega t_0}\int_{-\infty}^{+\infty} x(t')e^{-\mathrm{i}\omega t'}\mathrm{d}t'=X(\mathrm{i}\omega)e^{\pm\mathrm{i}\omega t_0}\end{aligned}$$

■ Q.E.D.

P3. Frequency shift:

$$\mathcal{F}^{-1}\left(X(\mathrm{i}\omega\pm\omega_0)\right)=x(t)e^{\mp\mathrm{i}\omega_0 t} \tag{7.1.529}$$

Proof 7.3.9. Let $\omega'=\omega\pm\omega_0$, i.e., $\omega=\omega'\mp\omega_0$, we have:

$$\begin{aligned}\mathcal{F}^{-1}[X(\mathrm{i}(\omega\pm\omega_0))]&=\frac{1}{2\pi}\int_{-\infty}^{+\infty} X(\mathrm{i}(\omega\pm\omega_0))e^{\mathrm{i}\omega t}\mathrm{d}\omega=\frac{1}{2\pi}\int_{-\infty}^{+\infty} X(\mathrm{i}\omega')e^{\mathrm{i}\omega(\omega'\mp\omega_0)}\mathrm{d}\omega'\\ &=e^{\mp\mathrm{i}\omega_0 t}\frac{1}{2\pi}\int_{-\infty}^{+\infty} X(\mathrm{i}\omega')e^{\mathrm{i}\omega'}\mathrm{d}\omega'=x(t)e^{\mp\mathrm{i}\omega_0 t}\end{aligned} \tag{7.1.530}$$

■ Q.E.D.

P4. Time reversal:

$$\mathcal{F}(x(-t))=X(-\omega) \tag{7.1.531}$$

Proof 7.3.10.

$$\mathcal{F}(x(-t))=\int\limits_{-\infty}^{+\infty} x(-t)e^{-\mathrm{i}\omega t}\mathrm{d}t \tag{7.1.532}$$

Replacing t by $-t'$, we get:

$$\mathcal{F}(x(-t))=-\int\limits_{+\infty}^{-\infty} x(t')e^{\mathrm{i}\omega t'}\mathrm{d}t'=\int\limits_{-\infty}^{+\infty} x(t')e^{\mathrm{i}\omega t'}\mathrm{d}t'=X(-\omega) \tag{7.1.533}$$

■ Q.E.D.

P5. Even and Odd Signals and Spectra:

If the signal $x(t)$ is an even (or odd) function of time, its spectrum $X(\mathrm{i}\omega)$ is an even (or odd) function of frequency:

$$\text{if } x(t)=x(-t) \text{ then } X(\mathrm{i}\omega)=X(-\mathrm{i}\omega) \tag{7.1.534}$$

and:

$$\text{if } x(t)=-x(-t) \text{ then } X(\mathrm{i}\omega)=-X(-\mathrm{i}\omega) \tag{7.1.535}$$

Proof 7.3.11. If $x(t)=x(-t)$ is even, then according to the time reversal property, we have:

$$X(\mathrm{i}\omega)=\mathcal{F}(x(t))=\mathcal{F}(x(-t))=X(-\omega) \tag{7.1.536}$$

i.e., the spectrum $X(\mathrm{i}\omega)=X(-\omega)$ is also even. Similarly, if $x(t)=-x(-t)$ is odd, we have:

$$X(\mathrm{i}\omega)=\mathcal{F}(x(t))=\mathcal{F}(-x(-t))=-X(-\omega) \tag{7.1.537}$$

i.e., the spectrum $X(\mathrm{i}\omega)=-X(-\omega)$ is also odd.

■ Q.E.D.

P6. Time and frequency scaling:

$$\mathcal{F}(x(at))=\frac{1}{a}X\left(\frac{\omega}{a}\right) \quad \text{or} \quad \mathcal{F}(ax(at))=X\left(\frac{\omega}{a}\right) \tag{7.1.538}$$

Proof 7.3.12. Let $u = at$, i.e., $t = u/a$, where $a > 0$ is a scaling factor, we have:

$$\mathcal{F}(x(at)) = \int_{-\infty}^{+\infty} x(at)e^{-\mathrm{i}\omega t}\mathrm{d}t = \int_{-\infty}^{+\infty} x(u)e^{-\mathrm{i}\omega u/a}\mathrm{d}(u/a) = \frac{1}{a}X\left(\frac{\omega}{a}\right) \tag{7.1.539}$$

Note that when $a < 1$, time function $x(at)$ is stretched, and $X(\mathrm{i}\omega/a)$ is compressed; when $a > 1$, $x(at)$ is compressed and $X(\mathrm{i}\omega/a)$ is stretched. This is a general feature of Fourier transform, i.e., compressing one of the $x(t)$ and $X(\mathrm{i}\omega)$ will stretch the other and vice versa. In particular, when $a \to 0$, $x(at)$ is stretched to approach a constant, and $X(\mathrm{i}\omega/a)/a$ is compressed with its value increased to approach an impulse; on the other hand, when $a \to +\infty$, $ax(at)$ is compressed with its value increased to approach an impulse and $X(\mathrm{i}\omega/a)$ is stretched to approach a constant.

■ Q.E.D.

P7. Complex Conjugation:

$$\text{if } \mathcal{F}(x(t)) = X(\mathrm{i}\omega), \quad \text{then } \mathcal{F}(x^*(t)) = X^*(-\mathrm{i}\omega) \tag{7.1.540}$$

Proof 7.3.13. Taking the complex conjugate of the inverse Fourier transform, we get:

$$x^*(t) = \left[\frac{1}{2\pi}\int_{-\infty}^{+\infty} X(\mathrm{i}\omega)e^{\mathrm{i}\omega t}\mathrm{d}\omega\right]^* = \frac{1}{2\pi}\int_{-\infty}^{+\infty} X^*(\mathrm{i}\omega)e^{-\mathrm{i}\omega t}\mathrm{d}\omega \tag{7.1.541}$$

Replacing ω by $-\omega'$ we get the desired result:

$$x^*(t) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} X^*(-\omega')e^{\mathrm{i}\omega' t}\mathrm{d}\omega' = \mathcal{F}^{-1}\left(X^*(-\omega)\right) \tag{7.1.542}$$

■ Q.E.D.

We further consider two special cases:

- If $x(t) = x^*(t)$ is real, then:

  $$\begin{aligned}\mathcal{F}(x(t)) &= X(\mathrm{i}\omega) = X_r(\mathrm{i}\omega) + \mathrm{i}X_i(\mathrm{i}\omega)\\ &= \mathcal{F}(x^*(t)) = X^*(-\omega) = X_r(-\omega) - \mathrm{i}X_i(-\omega)\end{aligned} \tag{7.1.543}$$

  i.e., the real part of the spectrum is even (with respect to frequency ω), and the imaginary part is odd:

  $$\begin{cases} X_r(\mathrm{i}\omega) = X_r(-\mathrm{i}\omega)\\ X_i(\mathrm{i}\omega) = -X_i(-\mathrm{i}\omega)\end{cases} \tag{7.1.544}$$

- If $x(t) = -x^*(t)$ is imaginary, then:

  $$\begin{aligned}\mathcal{F}(x(t)) &= X(\mathrm{i}\omega) = X_r(\mathrm{i}\omega) + \mathrm{i}X_i(\mathrm{i}\omega)\\ &= \mathcal{F}(-x^*(t)) = -X^*(-\mathrm{i}\omega) = -X_r(-\mathrm{i}\omega) + \mathrm{i}X_i(-\mathrm{i}\omega)\end{aligned} \tag{7.1.545}$$

  i.e., the real part of the spectrum is odd, and the imaginary part is even:

  $$\begin{cases} X_r(\mathrm{i}\omega) = -X_r(-\mathrm{i}\omega)\\ X_i(\mathrm{i}\omega) = X_i(-\mathrm{i}\omega)\end{cases} \tag{7.1.546}$$

If the time signal $x(t)$ is one of the four combinations shown in the table (real even, real odd, imaginary even, and imaginary odd), then its spectrum $X(\mathrm{i}\omega)$ is given in the corresponding table entry:

	if $x(t)$ is real X_r even, X_i odd	if $x(t)$ is imaginary X_r odd, X_i even
if $x(t)$ is Even X_r and X_i even	$X_i = 0$, $X = X_r$ even	$X_r = 0$, $X = X_i$ even
if $x(t)$ is Odd X_r and X_i odd	$X_r = 0$, $X = X_i$ odd	$X_i = 0$, $X = X_r$ odd

Note that if a real or imaginary part in the table is required to be both even and odd at the same time, it has to be zero.

These properties are summarized below:

	$x(t) = x_r(t) + \mathrm{i}x_i(t)$	$X(\mathrm{i}\omega) = X_r(\mathrm{i}\omega) + \mathrm{i}X_i(\mathrm{i}\omega)$
1	real $x(t) = x_r(t)$	even $X_r(\mathrm{i}\omega)$, odd $X_i(\mathrm{i}\omega)$
2	real and even $x(-t) = x_r(t)$	real and even $X_r(\mathrm{i}\omega)$
3	real and odd $x(-t) = -x_r(t)$	imaginary and odd $X_i(\mathrm{i}\omega)$
4	imaginary $x(t) = x_i(t)$	odd $X_r(\mathrm{i}\omega)$, even $X_i(\mathrm{i}\omega)$
5	imaginary and even $x(-t) = x_i(t)$	imaginary and even $X_i(\mathrm{i}\omega)$
6	imaginary and odd $x(-t) = -x_i(t)$	real and odd $X_r(\mathrm{i}\omega)$

As any signal can be expressed as the sum of its even and odd components, the first three items above indicate that the spectrum of the even part of a real signal is real and even, and the spectrum of the odd part of the signal is imaginary and odd.

P8. Symmetry (or Duality):

$$\text{if } \mathcal{F}(x(t)) = X(\mathrm{i}\omega), \text{ then } \mathcal{F}(X(t)) = 2\pi\, x(-\mathrm{i}\omega) \tag{7.1.547}$$

Or in a more symmetric form:

$$\text{if } \mathcal{F}(x(t)) = X(f), \text{ then } \mathcal{F}(X(t)) = x(-f) \tag{7.1.548}$$

Proof 7.3.14. As $\mathcal{F}(x(t)) = X(\mathrm{i}\omega)$, we have:

$$x(t) = \mathcal{F}^{-1}\left(X(\mathrm{i}\omega)\right) = \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\mathrm{i}\omega)e^{\mathrm{i}\omega t}\mathrm{d}\omega \tag{7.1.549}$$

Letting $t' = -t$, we get:

$$x(-t') = \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\mathrm{i}\omega)e^{-\mathrm{i}\omega t'}\mathrm{d}\omega \tag{7.1.550}$$

Interchanging t' and ω we get:

$$2\pi x(-\omega)=\int\limits_{-\infty}^{+\infty}X(t')e^{-\mathrm{i}\omega t'}\mathrm{d}t'=\mathcal{F}(X(t)) \tag{7.1.551}$$

or:

$$x(-f)=\int\limits_{-\infty}^{+\infty}X(t')e^{-\mathrm{i}2\pi f t'}\mathrm{d}t'=\mathcal{F}(X(t)) \tag{7.1.552}$$

In particular, if the signal is even:

$$x(t)=x(-t) \tag{7.1.553}$$

then we have:

$$\text{if }\ \mathcal{F}(x(t))=X(f)\ \text{ then }\mathcal{F}(X(t))=x(f) \tag{7.1.554}$$

■ Q.E.D.

For example, the spectrum of an even square wave is a sinc function, and the spectrum of a sinc function is an even square wave.

P9. Multiplication theorem:

$$\int\limits_{-\infty}^{+\infty}x(t)y^*(t)\mathrm{d}t=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}X(\mathrm{i}\omega)Y^*(\mathrm{i}\omega)\mathrm{d}\omega \tag{7.1.555}$$

Proof 7.3.15.

$$\begin{aligned}\int\limits_{-\infty}^{+\infty}x(t)y^*(t)\mathrm{d}t&=\int\limits_{-\infty}^{+\infty}x(t)\left[\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}Y^*(\mathrm{i}\omega)e^{-\mathrm{i}\omega t}\mathrm{d}\omega\right]\mathrm{d}t\\&=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}Y^*(\mathrm{i}\omega)\left[\int\limits_{-\infty}^{+\infty}x(t)e^{-\mathrm{i}\omega t}\mathrm{d}t\right]\mathrm{d}\omega=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}X(\mathrm{i}\omega)Y^*(\mathrm{i}\omega)\mathrm{d}\omega\end{aligned} \tag{7.1.556}$$

■ Q.E.D.

P10. Parseval's equation for the Fourier transform (for more details see page 1756):

In the special case when $y(t)=x(t)$, the above becomes the Parseval's equation:

$$\int\limits_{-\infty}^{+\infty}|x(t)|^2\mathrm{d}t=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}|X(\mathrm{i}\omega)|^2\mathrm{d}\omega=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}S_X(\mathrm{i}\omega)\mathrm{d}\omega=\text{Total energy in }x(t) \tag{7.1.557}$$

where:

$$S_X(\mathrm{i}\omega)\triangleq|X(\mathrm{i}\omega)|^2 \tag{7.1.558}$$

is the energy density function, commonly named "power spectrum", representing how the signal's energy is distributed along the frequency axes. The total energy contained in the signal is obtained by integrating $S(\mathrm{i}\omega)$ over the entire frequency axes.

The Parseval's equation also indicates that the energy or information contained in the signal is reserved, i.e., the signal is represented equivalently in either the time or frequency domain with no energy gained or lost!

The latter relation is more commonly written:

$$\boxed{P_f = |\mathcal{F}(x(t))(\omega)|^2} \tag{7.1.559}$$

or more simply:

$$P_f = |\mathcal{F}(x(t))|^2 \tag{7.1.560}$$

✍**Example:**

We have already proved in the section of Sequences and Series that the Fourier transform of the square pulse was given by (see page 1763):

$$\mathcal{F}(\text{rect}(t)) = A\Delta t\text{sinc}(\pi f\Delta t) \tag{7.1.561}$$

Hence:

$$P_f = (A\Delta t\text{sinc}(\pi f\Delta t))^2 \tag{7.1.562}$$

The energy spectrum of the pulse we have just calculated shows a great similarity with the Fraunhofer diffraction pattern due to a narrow slit (see section Wave Optics page 4492). In reality, it is more than a similarity because it is possible to prove in physics that any diffraction pattern is the Fourier transform of the object that is the cause!

P11. Correlation:

The "cross-correlation" of two real signals $x(t)$ and $y(t)$ is defined as (notice that it is strictly equivalent to the definition of the continuous convolution seen just earlier above at page 2293):

$$R_{xy}(t) \triangleq \int\limits_{-\infty}^{+\infty} x(\tau)y(\tau - t)\mathrm{d}\tau = \int\limits_{-\infty}^{+\infty} x(t+\tau)y(\tau)\mathrm{d}\tau \tag{7.1.563}$$

Specially, when $x(t) = y(t)$, the above becomes the "auto-correlation" of signal $x(t)$:

$$R_x(t) \triangleq \int\limits_{-\infty}^{+\infty} x(\tau)x(\tau - t)\mathrm{d}\tau \tag{7.1.564}$$

Assuming $\mathcal{F}(x(t)) = X(\mathrm{i}\omega)$, we have $\mathcal{F}(x(t-\tau)) = X(\mathrm{i}\omega)e^{-\mathrm{i}\omega\tau}$ and according to multiplication theorem, $R_x(\tau)$ can be written as:

$$\begin{aligned} R_x(\tau) &= \int\limits_{-\infty}^{+\infty} x(t)x(t-\tau)\mathrm{d}t = \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\mathrm{i}\omega)X^*(\mathrm{i}\omega)e^{\mathrm{i}\omega\tau}\mathrm{d}\omega \\ &= \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} |X(\mathrm{i}\omega)|^2 e^{\mathrm{i}\omega\tau}\mathrm{d}\omega = \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} S_X(\mathrm{i}\omega)e^{\mathrm{i}\omega\tau}\mathrm{d}\omega = \mathcal{F}^{-1}\left(S_X(\mathrm{i}\omega)\right) \end{aligned} \tag{7.1.565}$$

i.e.:

$$\mathcal{F}(R_x(t)) = S_X(\mathrm{i}\omega) \tag{7.1.566}$$

that is, the auto-correlation and the energy density function of a signal $x(t)$ are a Fourier transform pair.

P12. Convolution Theorems:

The "convolution theorem" states that convolution in time domain corresponds to multiplication in frequency domain and vice versa:

$$\mathcal{F}(x(t) * y(t)) = X(\mathrm{i}\omega)\,Y(\mathrm{i}\omega) \quad (a) \tag{7.1.567}$$

$$\mathcal{F}(x(t)\,y(t)) = X(\mathrm{i}\omega) * Y(\mathrm{i}\omega) \quad (b) \tag{7.1.568}$$

Let us start with the proof of (a)!

Proof 7.3.16.

$$\begin{aligned} \mathcal{F}(x(t)*y(t)) &= \int\limits_{-\infty}^{+\infty}\left[\int\limits_{-\infty}^{+\infty} x(\tau)y(t-\tau)\mathrm{d}\tau\right]e^{-\mathrm{i}\omega t}\mathrm{d}t \\ &= \int\limits_{-\infty}^{+\infty} x(\tau)\left[\int\limits_{-\infty}^{+\infty} y(t-\tau)e^{-\mathrm{i}\omega t}\mathrm{d}t\right]\mathrm{d}\tau \\ &= \int\limits_{-\infty}^{+\infty} x(\tau)e^{-\mathrm{i}\omega\tau}\left[\int\limits_{-\infty}^{+\infty} y(t-\tau)e^{-\mathrm{i}\omega(t-\tau)}\mathrm{d}(t-\tau)\right]\mathrm{d}\tau \\ &= X(\mathrm{i}\omega)\,Y(\mathrm{i}\omega) \end{aligned} \tag{7.1.569}$$

■ Q.E.D.

And now let us continue with the proof of (b)!

Proof 7.3.17.

$$\begin{aligned}\mathcal{F}(x(t)\,y(t)) &= \int\limits_{-\infty}^{+\infty} x(t)\,y(t)e^{-\mathrm{i}\omega t}\mathrm{d}t\\ &= \int\limits_{-\infty}^{+\infty}\left[\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\mathrm{i}\omega')e^{\mathrm{i}\omega' t}\mathrm{d}\omega'\right] y(t)e^{-\mathrm{i}\omega t}\mathrm{d}t\\ &= \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\mathrm{i}\omega')\left[\int\limits_{-\infty}^{+\infty} y(t)e^{\mathrm{i}\omega' t}e^{-\mathrm{i}\omega t}\mathrm{d}t\right]\mathrm{d}\omega'\\ &= \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\mathrm{i}\omega')\left[\int\limits_{-\infty}^{+\infty} y(t)e^{-\mathrm{i}(\omega-\omega')t}\mathrm{d}t\right]\mathrm{d}\omega'\\ &= \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\mathrm{i}\omega')Y(\mathrm{i}(\omega-\omega'))\mathrm{d}\omega' = X(\mathrm{i}\omega)*Y(\mathrm{i}\omega)\end{aligned} \tag{7.1.570}$$

■ Q.E.D.

P13. Time Derivative:

$$\mathcal{F}\left(\frac{\mathrm{d}}{\mathrm{d}t}x(t)\right) = \mathrm{i}\omega\, X(\mathrm{i}\omega) \tag{7.1.571}$$

Proof 7.3.18. Differentiating the inverse Fourier transform $X(\mathrm{i}\omega)$ with respect to t we get:

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}x(t) = \frac{\mathrm{d}}{\mathrm{d}t}\left[\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\mathrm{i}\omega)e^{\mathrm{i}\omega t}\mathrm{d}\omega\right] &= \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\mathrm{i}\omega)\frac{\mathrm{d}}{\mathrm{d}t}e^{\mathrm{i}\omega t}\mathrm{d}\omega\\ = \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}[\mathrm{i}\omega X(\mathrm{i}\omega)]e^{\mathrm{i}\omega t}\mathrm{d}\omega = \mathcal{F}^{-1}(\mathrm{i}\omega X(\mathrm{i}\omega))\end{aligned} \tag{7.1.572}$$

Repeating this process we get:

$$\mathcal{F}\left(\frac{\mathrm{d}^n}{\mathrm{d}t^n}x(t)\right) = (\mathrm{i}\omega)^n X(\mathrm{i}\omega) \tag{7.1.573}$$

■ Q.E.D.

P14. Time Integration:

First consider the Fourier transform of the following two signals:

$$u(t) = \begin{cases} 0 & t<0\\ 1 & t>0\end{cases}, \qquad \mathrm{sgn}(t) = \begin{cases} -1/2 & t<0\\ +1/2 & t>0\end{cases} = u(t) - \frac{1}{2} \tag{7.1.574}$$

$$\frac{\mathrm{d}}{\mathrm{d}t}u(t)=\delta(t),\qquad \frac{\mathrm{d}}{\mathrm{d}t}\mathrm{sgn}(t)=\frac{\mathrm{d}}{\mathrm{d}t}\left[u(t)-\frac{1}{2}\right]=\delta(t) \tag{7.1.575}$$

According to the time derivative property above:

$$X(\mathrm{i}\omega)=\mathcal{F}(x(t))=\frac{1}{\mathrm{i}\omega}\mathcal{F}\left(\frac{\mathrm{d}}{\mathrm{d}t}x(t)\right) \tag{7.1.576}$$

we get:

$$\mathcal{F}(u(t))=\frac{1}{\mathrm{i}\omega}\mathcal{F}\left(\frac{\mathrm{d}}{\mathrm{d}t}x(t)\right)=\frac{1}{\mathrm{i}\omega}\mathcal{F}(\delta(t))=\frac{1}{\mathrm{i}\omega} \tag{7.1.577}$$

and:

$$\mathcal{F}(\mathrm{sgn}(t))=\frac{1}{\mathrm{i}\omega}\mathcal{F}\left(\frac{\mathrm{d}}{\mathrm{d}t}\mathrm{sgn}(t)\right)=\frac{1}{\mathrm{i}\omega}\mathcal{F}(\delta(t))=\frac{1}{\mathrm{i}\omega} \tag{7.1.578}$$

Why do the two different functions have the same transform?

In general, any two function $f(t)$ and $g(t)=f(t)+c^{te}$ with a constant difference c^{te} have the same derivative $\mathrm{d}\,f(t)/\mathrm{d}t$, and therefore they have the same transform according the above method. This problem is obviously caused by the fact that the constant difference c^{te} is lost in the derivative operation.

To recover this constant difference in time domain, a delta function needs to be added in frequency domain. Specifically, as function $\mathrm{sgn}(t)$ does not have DC component, its transform does not contain a delta:

$$\mathcal{F}(\mathrm{sgn}(t))=\frac{1}{\mathrm{i}\omega} \tag{7.1.579}$$

To find the transform of $u(t)$, consider:

$$u(t)=\mathrm{sgn}(t)+\frac{1}{2} \tag{7.1.580}$$

and:

$$\mathcal{F}(u(t))=\mathcal{F}(\mathrm{sgn}(t))+\mathcal{F}\left(\frac{1}{2}\right)=\frac{1}{\mathrm{i}\omega}+\pi\delta(\omega) \tag{7.1.581}$$

The added impulse term $\pi\delta(\omega)$ directly reflects the constant $c=1/2$ in time domain.

Now we show that the Fourier transform of a time integration is:

$$\mathcal{F}\left(\int\limits_{-\infty}^{t}x(\tau)\mathrm{d}\tau\right)=\frac{1}{\mathrm{i}\omega}X(\mathrm{i}\omega)+\pi X(0)\delta(\omega) \tag{7.1.582}$$

Proof 7.3.19. First consider the convolution of $x(t)$ and $u(t)$:

$$x(t)*u(t)=\int\limits_{-\infty}^{+\infty}x(\tau)u(t-\tau)\mathrm{d}\tau=\int\limits_{-\infty}^{t}x(\tau)\mathrm{d}\tau \tag{7.1.583}$$

Due to the convolution theorem, we have:

$$\mathcal{F}\left(\int\limits_{-\infty}^{t}x(\tau)\mathrm{d}\tau\right)=\mathcal{F}(x(t)*u(t))=X(\mathrm{i}\omega)\left[\frac{1}{\mathrm{i}\omega}+\pi\delta(\omega)\right]=\frac{1}{\mathrm{i}\omega}X(\mathrm{i}\omega)+\pi X(0)\delta(\omega) \tag{7.1.584}$$

■ Q.E.D.

P15. Frequency Derivative:

$$\mathcal{F}(tx(t)) = \mathrm{i}\frac{\mathrm{d}}{\mathrm{d}\omega}X(\mathrm{i}\omega) \tag{7.1.585}$$

Proof 7.3.20. We differentiate the Fourier transform of $x(t)$ with respect to ω to get:

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}\omega}X(\mathrm{i}\omega) &= \frac{\mathrm{d}}{\mathrm{d}\omega}\left[\int\limits_{-\infty}^{+\infty} x(t)e^{-\mathrm{i}\omega t}\mathrm{d}t\right] = \int\limits_{-\infty}^{+\infty} x(t)\frac{\mathrm{d}}{\mathrm{d}\omega}e^{-\mathrm{i}\omega t}\mathrm{d}t\\ &= \int\limits_{-\infty}^{+\infty} x(t)(-\mathrm{i}t)e^{-\mathrm{i}\omega t}\mathrm{d}t\end{aligned} \tag{7.1.586}$$

i.e.:

$$\mathcal{F}(-\mathrm{i}tx(t)) = \frac{\mathrm{d}}{\mathrm{d}\omega}X(\mathrm{i}\omega) \tag{7.1.587}$$

Multiplying both sides by i, we get:

$$\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}\omega}X(\mathrm{i}\omega) = \int\limits_{-\infty}^{+\infty} tx(t)e^{-\mathrm{i}\omega t}\mathrm{d}t = \mathcal{F}(tx(t)) \tag{7.1.588}$$

Repeating this process we get:

$$\mathcal{F}(t^n x(t)) = \mathrm{i}^n\frac{\mathrm{d}^n}{\mathrm{d}\omega^n}X(\mathrm{i}\omega) \tag{7.1.589}$$

■ Q.E.D.

Property name	**Time domainfunction** $f(t)$	**Fourier Transform** $F(\omega)$
Linearity	$af_1(t)+bf_2(t)$	$aF_1(\omega)+bF_2(\omega)$
Time Scaling	$f(at)$	$\frac{1}{\lvert a \rvert}F\left(\frac{\omega}{a}\right)$

Table 7.7: **Summary of most common Fourier transform properties**

7.1.5.1.1.2 Usual Fourier transforms

There are in math and physics many Fourier transforms of signals we see quite frequently (but not exclusively). Furthermore, all Fourier transforms proved below will be used in the various chapters on Physics, Engineering, Atomistic, Social Mathematics, etc of this textbook. So, as in any formula booklet, we propose you the most well known Fourier transforms but with... the proofs!

1. Impulse:

   As shown above:

   $$\mathcal{F}(\delta(t-a))=\int\limits_{-\infty}^{+\infty}\delta(t-a)e^{-\mathrm{i}\omega t}\mathrm{d}t=e^{\mathrm{i}\omega a} \qquad (7.1.590)$$

   or:

   $$\mathcal{F}(\delta(t))=1 \qquad (7.1.591)$$

   It is therefore immediate that the inverse Fourier transform of the complex exponential is the Dirac delta:

   $$\mathcal{F}^{-1}(e^{\mathrm{i}\omega a})=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}e^{\mathrm{i}\omega a}e^{-\mathrm{i}\omega t}\mathrm{d}t=\delta(t-a) \qquad (7.1.592)$$

2. Unit Step:

   As shown above:

   $$\mathcal{F}(u(t))=\frac{1}{\mathrm{i}\omega}+\pi\delta(\omega) \qquad (7.1.593)$$

3. Constant:

   As shown above:

   $$\mathcal{F}(x(t))=\int\limits_{-\infty}^{+\infty}e^{-\mathrm{i}\omega t}\mathrm{d}t=2\pi\,\delta(\omega) \qquad (7.1.594)$$

   This is a useful formula.

4. Complex exponential:

   The spectrum of a complex exponential can be found from the above due to the frequency shift property:

   $$\mathcal{F}(e^{\mathrm{i}\omega_0 t})=2\pi\,\delta(\omega-\omega_0) \qquad (7.1.595)$$

   Let us write this more explicitly:

   $$\mathcal{F}(e^{\mathrm{i}\omega_0 t})=\int\limits_{-\infty}^{+\infty}e^{\mathrm{i}\omega_0 t}e^{-\mathrm{i}\omega t}\mathrm{d}t=\int\limits_{-\infty}^{+\infty}e^{\mathrm{i}(\omega_0-\omega)t}\mathrm{d}t=\left.\frac{e^{\mathrm{i}(\omega_0-\omega)t}}{\mathrm{i}(\omega_0-\omega)}\right|_{-\infty}^{+\infty}=\text{hummm....} \qquad (7.1.596)$$

Now let us try to solve this using the physicist way... Using what we have just seen before (the inverse Fourier transform of the Dirac pulse), we have:

$$\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} e^{\mathrm{i}\omega a}e^{-\mathrm{i}\omega t}\mathrm{d}t=\delta(t-a) \tag{7.1.597}$$

it comes obviously after rearranging (multiplying both sides by 2π):

$$\int\limits_{-\infty}^{+\infty} e^{\mathrm{i}\omega a}e^{-\mathrm{i}\omega t}\mathrm{d}t=2\pi\delta(t-a) \tag{7.1.598}$$

5. Sinusoids:

$$x(t)=\cos(\omega_0 t)=\frac{1}{2}(e^{\mathrm{i}\omega_0 t}+e^{-\mathrm{i}\omega_0 t}) \tag{7.1.599}$$

Therefore:

$$X(\mathrm{i}\omega)=\mathcal{F}(\cos(\omega_0 t))=\frac{1}{2}\left(\mathcal{F}(e^{\mathrm{i}\omega_0 t})+\mathcal{F}(e^{-\mathrm{i}\omega_0 t})\right)=\pi[\delta(\omega-\omega_0)+\delta(\omega+\omega_0)] \tag{7.1.600}$$

Similarly, we have:

$$X(\mathrm{i}\omega)=\mathcal{F}(\sin(\omega_0 t))=\frac{\pi}{\mathrm{i}}[\delta(\omega-\omega_0)-\delta(\omega+\omega_0)] \tag{7.1.601}$$

6. Exponential decay (right-sided):

$$x(t)=e^{-at}u(t)\quad (a>0) \tag{7.1.602}$$

Therefore:

$$\begin{aligned}\mathcal{F}(e^{-at}u(t))&=\int\limits_{-\infty}^{+\infty} x(t)e^{-\mathrm{i}\omega t}\mathrm{d}t=\int\limits_{0}^{+\infty} e^{-at}e^{-\mathrm{i}\omega t}\mathrm{d}t\\&=\frac{-1}{a+\mathrm{i}\omega}e^{-(a+\mathrm{i}\omega)t}|_0^{+\infty}=\frac{1}{a+\mathrm{i}\omega}\end{aligned} \tag{7.1.603}$$

7. Exponential decay (left-sided):

Due to the time reversal property, we also have (for $a>0$):

$$\mathcal{F}(e^{at}u(-t))=\frac{1}{a-\mathrm{i}\omega} \tag{7.1.604}$$

or:

$$\mathcal{F}(-e^{at}u(-t))=\frac{1}{\mathrm{i}\omega-a} \tag{7.1.605}$$

8. Exponential decay (two-sided):

$$x(t)=e^{-a|t|}\quad(a>0) \tag{7.1.606}$$

As the two-sided exponential decay is the sum of the right and left-sided exponential decays, its spectrum of $x(t)$ is the sum of their spectra due to linearity:

$$\mathcal{F}(e^{-a|t|})=\frac{1}{a+\mathrm{i}\omega}+\frac{1}{a-\mathrm{i}\omega}=\frac{2a}{a^2+\omega^2} \tag{7.1.607}$$

9. Comb function:

The comb function is defined as:

$$\text{comb}(t)=\sum_{n=-\infty}^{+\infty}\delta(t-nT) \tag{7.1.608}$$

Its Fourier series coefficient is:

$$\text{COMB}[k]=\frac{1}{T}\int\limits_{-T/2}^{T/2}\text{comb}(t)e^{-\mathrm{i}\omega_0 t}\mathrm{d}t=\frac{1}{T}\int\limits_{-T/2}^{T/2}\delta(t)e^{-\mathrm{i}\omega_0 t}\mathrm{d}t=\frac{1}{T} \tag{7.1.609}$$

and its spectrum is:

$$\text{COMB}(\mathrm{i}\omega)=\frac{2\pi}{T}\sum_{k=-\infty}^{+\infty}\delta\left(\omega-k\omega_0\right)=\frac{1}{T}\sum_{k=-\infty}^{+\infty}\delta\left(f-\frac{k}{T}\right) \tag{7.1.610}$$

We see that the spectrum of an impulse train with time interval T is also an impulse train with frequency interval $\omega_0=2\pi/T$. Also, according to the definition of the Fourier transform, we have:

$$\begin{aligned}\text{COMB}(\mathrm{i}\omega)&=\int\limits_{-\infty}^{+\infty}\text{comb}(t)e^{-\mathrm{i}\omega t}\mathrm{d}t=\int\limits_{-\infty}^{+\infty}\left[\sum_{n=-\infty}^{+\infty}\delta(t-nT)\right]e^{-\mathrm{i}\omega t}\mathrm{d}t\\&=\sum_{n=-\infty}^{+\infty}\int\limits_{-\infty}^{+\infty}\delta(t-nT)e^{-\mathrm{i}\omega t}\mathrm{d}t=\sum_{n=-\infty}^{+\infty}e^{-\mathrm{i}\omega nT}\end{aligned} \tag{7.1.611}$$

Therefore we have this equation:

$$\sum_{n=-\infty}^{+\infty}e^{-\mathrm{i}\omega nT}=\frac{2\pi}{T}\sum_{k=-\infty}^{+\infty}\delta(\omega-k\omega_0)=\frac{1}{T}\sum_{k=-\infty}^{+\infty}\delta\left(f-\frac{k}{T}\right) \tag{7.1.612}$$

which can be compared with the equation in continuous case:

$$\int\limits_{-\infty}^{+\infty}e^{-\mathrm{i}\omega t}\mathrm{d}t=2\pi\delta(\omega)=\delta(f) \tag{7.1.613}$$

10. Square wave (for another detailed derivation see page 1763):

    A square wave or rectangular function of width a can be considered as the difference between two unit step functions:

$$\text{rect}_a(t)=u(t+a)-u(t-a)=\begin{cases}1 & -a\leq t<a\\ 0 & \text{else}\end{cases}\tag{7.1.614}$$

    and due to linearity, its Fourier spectrum is the difference between the two corresponding spectra:

$$\begin{aligned}\mathcal{F}(\text{rect}_a(t))&=\mathcal{F}(u(t+a))-\mathcal{F}(u(t-a))=\frac{1}{\mathrm{i}\omega}e^{\mathrm{i}a\omega}-\frac{1}{\mathrm{i}\omega}e^{-\mathrm{i}a\omega}\\&=\frac{2}{\omega}\,\frac{e^{\mathrm{i}a\omega}-e^{-\mathrm{i}a\omega}}{2\mathrm{i}}=\frac{2}{\omega}\sin(a\omega)=\frac{2a}{\omega}\text{sinc}(a\omega)\end{aligned}\tag{7.1.615}$$

11. Sinc function:

    The spectrum of an ideal low-pass filter is:

$$X(\mathrm{i}\omega)=\begin{cases}1 & -a\leq\omega<a\\ 0 & \text{else}\end{cases}\tag{7.1.616}$$

    and its impulse response can be found by inverse Fourier transform:

$$x(t)=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}X(\mathrm{i}\omega)e^{\mathrm{i}\omega t}\mathrm{d}\omega=\frac{1}{2\pi\mathrm{i}t}(e^{\mathrm{i}at}-e^{-\mathrm{i}at})=\frac{\sin(at)}{\pi t}\tag{7.1.617}$$

12. Triangle function:

$$x(t)=\text{triangle}(t)=\begin{cases}1-|t| & |t|<1\\ 0 & |t|\geq 1\end{cases}\tag{7.1.618}$$

    As $x(t)$ is an even function, its Fourier transform is:

$$\begin{aligned}\mathcal{F}(x(t))&=\int\limits_{-\infty}^{+\infty}x(t)e^{-\mathrm{i}\omega t}\mathrm{d}t=2\int\limits_{0}^{1}(1-t)\cos(\omega t)\mathrm{d}t\\&=2\left[\int\limits_{0}^{1}\cos(\omega t)\mathrm{d}t-\int\limits_{0}^{1}t\,\cos(\omega t)\mathrm{d}t\right]=\frac{2}{\omega}\left[\sin(\omega)-\int\limits_{0}^{1}t\mathrm{d}\sin(\omega t)\right]\\&=\frac{2}{\omega}\left[\sin(\omega)-(t\,\sin(\omega t)|_0^1-\int\limits_{0}^{1}\sin(\omega t)\mathrm{d}t)\right]=\frac{2}{\omega^2}\cos(\omega t)|_1^0\\&=\frac{2}{\omega^2}(1-\cos(\omega))=\left(\frac{2}{\omega}\right)^2\sin^2\left(\frac{\omega}{2}\right)=\frac{\sin^2(\pi f)}{(\pi f)^2}=\text{sinc}^2(\omega)\end{aligned}\tag{7.1.619}$$

    Alternatively, as the triangle function is the convolution of two square functions ($a=1/2$), its Fourier transform can be more conveniently obtained according to the convolution theorem as:

$$\mathcal{F}(\text{triangle}(t))=\mathcal{F}(\text{rect}(t)*\text{rect}(t))=\text{sinc}(\omega)\,\text{sinc}(\omega)=\left(\frac{2}{\omega}\right)^2\sin^2\left(\frac{\omega}{2}\right)\tag{7.1.620}$$

13. Gaussian function:

    The Fourier transform of a Gaussian or bell-shaped function $x(t)=e^{-\pi t^2}$ is:

$$\begin{aligned}X(\mathrm{i}\omega)=\mathcal{F}(x(t))&=\int\limits_{-\infty}^{+\infty}[e^{-\pi t^2}]e^{-\mathrm{i}\omega t}\mathrm{d}t\\&=\int\limits_{-\infty}^{+\infty}e^{-\pi(t^2+\mathrm{i}2ft)}\mathrm{d}t=e^{\pi(\mathrm{i}f)^2}\int\limits_{-\infty}^{+\infty}e^{-\pi[t^2+\mathrm{i}2ft+(\mathrm{i}f)^2]}\mathrm{d}t\\&=e^{-\pi f^2}\int\limits_{-\infty}^{+\infty}e^{-\pi(t+\mathrm{i}f)^2}\mathrm{d}(t+\mathrm{i}f)=e^{-\pi f^2}\end{aligned}\tag{7.1.621}$$

    Here we have used the identity:

$$\int\limits_{-\infty}^{+\infty}e^{-\pi x^2}\mathrm{d}x=1\tag{7.1.622}$$

    We see that the Fourier transform of a bell-shaped function is also a bell-shaped function:

$$\mathcal{F}(e^{-\pi t^2})=e^{-\pi f^2}\tag{7.1.623}$$

    Note that the area underneath either $x(t)$ or $X(\mathrm{i}\omega)$ is unity. Moreover, due to the property of time and frequency scaling, we have:

$$\mathcal{F}(a\,e^{-\pi(at)^2})=e^{-\pi(f/a)^2}\tag{7.1.624}$$

    Note that if $a=1/\sqrt{2\pi\sigma^2}$, then $a\,x(at)$ above is a normal distribution with variance σ^2 and mean $\mu=0$. If we let $a\rightarrow\infty$, $x(t)$ becomes narrower and taller and approaches $\delta(t)$, and its spectrum $e^{-\pi(f/a)^2}$ becomes wider and approaches constant 1. On the other hand, if we rewrite the above as:

$$\mathcal{F}(e^{-\pi(at)^2})=\frac{1}{a}e^{-\pi(f/a)^2}\tag{7.1.625}$$

    and let $a\rightarrow 0$, $x(t)$ approaches 1 and $X(\mathrm{i}\omega)$ approaches $\delta(\omega)$.

To summarize here is a table with the most important Fourier Transforms:

Function $f(t)$	**Fourier Transform** $\mathcal{F}(f(t))$
$f(t-t_0)$	$\mathcal{F}(\omega)e^{-\mathrm{i}\omega t_0}$
$f(t)e^{\mathrm{i}\omega_0 t}$	$\mathcal{F}(\omega-\omega_0)$
$f(\alpha t)$	$\dfrac{1}{\lvert\alpha\rvert}\mathcal{F}\left(\dfrac{\omega}{\alpha}\right)$
$\mathcal{F}(t)$	$2\pi f(-\omega)$
$\dfrac{\mathrm{d}^n f(t)}{\mathrm{d}t^n}$	$(\mathrm{i}\omega)^n\mathcal{F}(\omega)$
$(-\mathrm{i}t)^n f(t)$	$\dfrac{\mathrm{d}^n\mathcal{F}(\omega)}{\mathrm{d}\omega^n}$
$\displaystyle\int_{-\infty}^{t} f(\tau)d\tau$	$\dfrac{\mathcal{F}(\omega)}{\mathrm{i}\omega}+\pi\mathcal{F}(0)\delta(\omega)$
$h\cdot\text{rect}\left(\dfrac{t}{a}\right)$	$h\cdot a\cdot\text{sinc}\left(\dfrac{\omega a}{2}\right)$
$\text{rect}(t)$	$\frac{2a}{\omega}\text{sinc}(a\omega)$
e^{-at^2}	$\dfrac{1}{\sqrt{2a}}e^{-\frac{\omega^2}{4a}}$
$\delta(t-a)$	1
c^{te}	$2\pi\delta(\omega)$
$u(t)$	$\dfrac{1}{\mathrm{i}\omega}+\pi\delta(\omega)$
$e^{i\omega_0 t}$	$2\pi\delta(\omega-\omega_0)$
$\cos(\omega_0 t)$	$\pi\left[\delta(\omega-\omega_0)+\delta(\omega+\omega_0)\right]$
$\sin(\omega_0 t)$	$-\mathrm{i}\pi\left[\delta(\omega-\omega_0)-\delta(\omega+\omega_0)\right]$
$e^{-at}u(t)$	$\dfrac{1}{a+\mathrm{i}\omega}$
$e^{at}u(t)$	$\dfrac{1}{a-\mathrm{i}\omega}$
$-e^{at}u(-t)$	$\dfrac{1}{\mathrm{i}\omega-a}$
$e^{-a\lvert t\rvert}$	$\dfrac{2a}{a^2+\omega^2}$
$\text{comb}(t)=\displaystyle\sum_{n=-\infty}^{+\infty}\delta(t-nT)$	$\displaystyle\sum_{n=-\infty}^{+\infty}e^{-i\omega nT}$
$\text{triangle}(t)$	$\text{sinc}^2(\omega)$

Table 7.8: **Most common Fourier transforms**

Now that we have seen quite a number of properties and usual Fourier Transform, let us go back to our heat equation determined in the section of Thermodynamics (see page 3684) in the form:

$$\frac{\partial u}{\partial t}-D\frac{\partial^2 u}{\partial x^2}=0 \tag{7.1.626}$$

And let us also be interested in the case where:

$$\begin{aligned} u(x,0)&=f(x)\\ f(\pm\infty)&\rightarrow 0 \end{aligned} \tag{7.1.627}$$

To simplify the writing, we will write the differential equation in the following form:

$$\partial_t u=D\partial_x^2 u \tag{7.1.628}$$

Let us take the Fourier transform relatively to x of this equality. Let us recall that for this purpose we have proved in the section of Sequences and Series and just earlier at page 2316 that (time derivative property):

$$\mathcal{F}(\partial_x^2 u(x))=(\mathrm{i}\omega)^2\mathcal{F}(u(x))=-\omega^2\mathcal{F}(u(x)) \qquad (7.1.629)$$

Let us put to simplify the notations:

$$\mathcal{F}(u(x))=\hat{u} \qquad (7.1.630)$$

As we take the Fourier transform with respect to x, we can take out the partial derivative of the integral of the Fourier transform such as:

$$\mathcal{F}(\partial_t u(x))=\partial_t\mathcal{F}(u(x))=\partial_t\hat{u} \qquad (7.1.631)$$

Our differential equation is then reduced to:

$$\partial_t\hat{u}=-\omega^2 D\hat{u} \qquad (7.1.632)$$

Thus explicitly:

$$\partial_t\left(\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}ue^{-\mathrm{i}\omega x}\mathrm{d}x\right)=-\omega^2 D\left(\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}ue^{-\mathrm{i}\omega x}\mathrm{d}x\right) \qquad (7.1.633)$$

We see then immediately with the simplified version that a particular solution is:

$$\hat{u}(\omega,t)=C(\omega)e^{-\omega^2 Dt} \qquad (7.1.634)$$

The constant has to be determined by the initial condition:

$$u(x,0)=f(x)\Rightarrow\hat{u}(\omega,0)=\hat{f}(x) \qquad (7.1.635)$$

Therefore:

$$\hat{u}(\omega,t)=C(\omega)e^{-\omega^2 Dt}=\hat{u}(\omega,0)e^{-\omega^2 Dt}=\hat{f}(x)e^{-\omega^2 Dt} \qquad (7.1.636)$$

Then it comes by doing the inverse Fourier transform in x:

$$u(x,t)=\mathcal{F}^{-1}(\hat{u}(\omega,t))=\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}\hat{f}(x)e^{-\omega^2 Dt}e^{\mathrm{i}\omega x}\mathrm{d}x=\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}\hat{f}(x)e^{-\omega^2 Dt+\mathrm{i}\omega x}\mathrm{d}\omega \qquad (7.1.637)$$

Now let's make a small change of notation by putting:

$$\omega=\lambda \qquad \hat{f}(x)=F(\omega)=F(\lambda) \qquad (7.1.638)$$

Then we have:

$$u(x,t)=\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}F(\omega)e^{-\lambda^2 Dt+\mathrm{i}\lambda x}\mathrm{d}\omega \qquad (7.1.639)$$

We then fall much more quickly on the same integral that we obtained in the section of Thermodynamics in our study of the heat equation, the finishing work being the same, the reader can refer to it!

We had also proved in the section Thermodynamics that we obtained:

$$u(x,t)=\frac{1}{2\sqrt{\pi Dt}}\int\limits_{-\infty}^{+\infty}e^{-\frac{(v-x)^2}{4Dt}}\mathrm{d}v \tag{7.1.640}$$

We then notice that the Fourier transform is not only a tool for analysing a frequency domain signal but also for solving some differential equations more quickly.

But as many times in mathematics, we must be careful using such a tool. They may be some trap and subtilities. Let us see on famous example!

We know that the set of solutions of the differential equation:

$$y'=0 \tag{7.1.641}$$

where y is a continuous function from $\mathbb{R}\mapsto\mathbb{C}$, is made of the set of constant functions!

Let us try to solve this equation using the Fourier transform. By taking the Fourier transform on the left and on the right we get:

$$\omega\mathcal{F}(y)=0 \tag{7.1.642}$$

An error would be to think that we can divide left and right by ω and thus get:

$$\mathcal{F}(y)=0 \tag{7.1.643}$$

In this case, taking the inverse transform would get $y=0$ as the only solution to the equation, then we would lose all other solutions.

In fact, what we must remember is that the Fourier transform is defined on the space of "temperate distributions" and that therefore, as long as we decide to use this integral transform to solve the differential equation above, we also decide, implicitly, to look for solutions in this space. Now in the space of temperate distributions, the equation $\omega\mathcal{F}(y)=0$ possesses an infinity of solutions that are given by (without proof) $c\cdot\delta$ where c is a complex number and δ is the Dirac distribution. As a result:

$$\hat{y}=c\cdot\delta \tag{7.1.644}$$

and taking the inverse transform we get indeed:

$$y=c^{te} \tag{7.1.645}$$

We therefore conclude that when we solve differential equations with the Fourier transform it must be remembered that in the space of temperate distributions the usual algebraic calculation rules are to be handled with care. This remark is obviously valid only for people who know the Fourier transform but have only a vague idea of what is a temperate distribution (which is normally the case for engineers....

7.1.5.1.2 Discrete Time Fourier Transform

A discrete-time signal can be considered as a continuous signal $x(t)$ sampled at a rate $F=1/t_0$ or $\Omega=2\pi/t_0$, where t_0 is the sampling period (time interval between two consecutive samples). The corresponding sampling function (comb function) is:

$$\text{comb}(t)=\sum_{m=-\infty}^{+\infty}\delta(t-mt_0) \tag{7.1.646}$$

The sampling process can be represented by:

$$x_s(t)=x(t)\,\text{comb}(t)=x(t)\sum_{m=-\infty}^{+\infty}\delta(t-mt_0)=\sum_{m=-\infty}^{+\infty}x[m]\delta(t-mt_0) \tag{7.1.647}$$

where $x[m]=x(mt_0)$ is the value of $x(t)$ at $t=mt_0$. The Fourier transform of this discrete signal (treated as a special case of continuous signal) is:

$$\begin{aligned}X(\mathrm{i}\omega)&=\int_{\infty}^{+\infty}x_s(t)e^{-\mathrm{i}\omega t}\mathrm{d}t=\int_{\infty}^{+\infty}\left[\sum_{m=-\infty}^{+\infty}x[m]\delta(t-mt_0)\right]e^{-\mathrm{i}\omega t}\mathrm{d}t\\&=\sum_{m=-\infty}^{+\infty}x[m]\int_{\infty}^{+\infty}\delta(t-mt_0)\,e^{-\mathrm{i}\omega t}\mathrm{d}t=\sum_{m=-\infty}^{+\infty}x[m]\,e^{-\mathrm{i}\omega mt_0}\end{aligned} \tag{7.1.648}$$

This is the forward Fourier transform (analysis) of a discrete signal $x_s(t)$. The spectrum $X(\mathrm{i}\omega)$ is periodic with period $\Omega=2\pi F=2\pi/t_0$:

$$X(\mathrm{i}(\omega+\Omega))=\sum_{m=-\infty}^{+\infty}x[m]e^{-\mathrm{i}(\omega+\Omega))mt_0}=\sum_{m=-\infty}^{+\infty}x[m]e^{-\mathrm{i}\omega mt_0}e^{-\mathrm{i}\Omega mt_0}=X(\mathrm{i}\omega) \tag{7.1.649}$$

as :

$$e^{-\mathrm{i}\Omega mt_0}=e^{-\mathrm{i}2m\pi}=1 \tag{7.1.650}$$

To get back the time signal $x[m]$ from its spectrum:

$$X(\mathrm{i}\omega)=\sum_{m=-\infty}^{+\infty}x[m]\,e^{-\mathrm{i}\omega mt_0} \tag{7.1.651}$$

we multiply the equation by $e^{\mathrm{i}\omega nt_0}/\Omega$ and integrate both sides with respect to ω over the period $\Omega=2\pi F=2\pi/t_0$ to obtain the inverse Fourier transform (synthesis):

$$\begin{aligned}\frac{1}{\Omega}\int_{\Omega}X(\mathrm{i}\omega)e^{\mathrm{i}\omega nt_0}\mathrm{d}\omega&=\frac{1}{\Omega}\int_{\Omega}[\sum_{m=-\infty}^{+\infty}x[m]e^{-\mathrm{i}\omega mt_0}]e^{\mathrm{i}\omega nt_0}\mathrm{d}\omega\\&=\sum_{m=-\infty}^{+\infty}x[m]\frac{1}{\Omega}\int_{\Omega}e^{-\mathrm{i}\omega(m-n)t_0}\mathrm{d}\omega=\sum_{m=-\infty}^{+\infty}x[m]\delta[m-n]=x[n]\end{aligned} \tag{7.1.652}$$

Note that here we used:

$$\frac{1}{\Omega}\int\limits_{\Omega} e^{-\mathrm{i}\omega(m-n)t_0}\mathrm{d}\omega=\frac{1}{\Omega}\int\limits_{\Omega} e^{-\mathrm{i}(m-n)2\pi\omega/\Omega}\mathrm{d}\omega=\delta[m-n]=\begin{cases}1 & m=n\\ 0 & m\neq n\end{cases} \tag{7.1.653}$$

which can be compared with:

$$\frac{1}{T}\int\limits_{T} e^{\mathrm{i}(m-n)\omega_0 t}\mathrm{d}t=\frac{1}{T}\int\limits_{T} e^{\mathrm{i}(m-n)2\pi t/T}\mathrm{d}t=\delta[m-n]=\begin{cases}1 & m=n\\ 0 & m\neq n\end{cases} \tag{7.1.654}$$

To summarize, the spectrum of a given discrete signal:

$$\boxed{x_s(t)=\sum_{m=-\infty}^{+\infty} x[m]\delta(t-mt_0)} \tag{7.1.655}$$

can be found by the "forward discrete Fourier transform" to be:

$$\boxed{X_\Omega(\mathrm{i}\omega)=\mathcal{F}[x[m]]=\sum_{m=-\infty}^{+\infty} x[m]e^{-\mathrm{i}\omega m t_0}=\sum_{m=-\infty}^{+\infty} x[m]e^{-\mathrm{i}2\pi m t_0}} \tag{7.1.656}$$

and the signal can be expressed by inverse Fourier transform:

$$\boxed{x[m]=\mathcal{F}^{-1}[X_\Omega(\mathrm{i}\omega)]=\frac{1}{\Omega}\int\limits_{\Omega} X_\Omega(\mathrm{i}\omega)e^{\mathrm{i}\omega m t_0}\mathrm{d}\omega=\int\limits_{F} X_F(f)e^{\mathrm{i}2\pi m t_0}\mathrm{d}f} \tag{7.1.657}$$

It is interesting to compare this discrete time Fourier transform pair with the Fourier series expansion (the Fourier transform of a periodic signal):

$$x_T(t)=\mathcal{F}^{-1}[X[n]]=\sum_{n=-\infty}^{+\infty} X[n]e^{\mathrm{i}n\omega_0 t}=\sum_{n=-\infty}^{+\infty} X[n]e^{\mathrm{i}2\pi n f_0 t} \tag{7.1.658}$$

$$X[n]=\mathcal{F}[x_T(t)]=\frac{1}{T}\int\limits_{T} x_T(t)e^{-\mathrm{i}n\omega_0 t}\mathrm{d}t=\frac{1}{T}\int\limits_{T} x_T(t)e^{-\mathrm{i}2\pi n f_0 t}\mathrm{d}t \tag{7.1.659}$$

with discrete spectrum:

$$X(\mathrm{i}\omega)=2\pi\sum_{n=-\infty}^{+\infty} X[n]\delta(\omega-n\omega_0)\quad\text{or}\quad X(f)=\sum_{n=-\infty}^{+\infty} X[n]\delta(f-nf_0) \tag{7.1.660}$$

We see symmetry between these two different forms of Fourier transform. If the signal $x(t)=x(t+T)$ is periodic, its spectrum $X(\mathrm{i}\omega)$ is discrete, the coefficients of the Fourier series with interval $\omega_0=2\pi/T$. On the other hand, if $x(t)$ is discrete with interval $t_0=2\pi/\Omega$, its spectrum $X(\mathrm{i}\omega)=X(\mathrm{i}\omega+\Omega)$ is periodic.

In particular, if the unit of time is so chosen that the sampling period is $t_0=1$, then $\Omega=2\pi/t_0=2\pi$, and the forward Fourier transform of a discrete signal becomes:

$$X(\mathrm{i}\omega)=\sum_{m=-\infty}^{+\infty} x[m]e^{-\mathrm{i}m\omega}=\sum_{m=-\infty}^{+\infty} x[m]e^{-\mathrm{i}m2\pi f} \tag{7.1.661}$$

The inverse transform becomes:

$$x_s[m] = \frac{1}{2\pi}\int\limits_0^{2\pi} X(\mathrm{i}\omega)e^{\mathrm{i}m\omega}\mathrm{d}\omega = \int\limits_0^{1} X(\mathrm{i}\omega)e^{\mathrm{i}m2\pi f}\mathrm{d}f \tag{7.1.662}$$

The spectrum $X(\mathrm{i}\omega) = X(\mathrm{i}\omega + 2\pi)$ is periodic.

Remark

The spectrum of a time signal (continuous or discrete) can be denoted by $X(\mathrm{i}\omega)$ or $X(f)$ to emphasize the fact that the spectrum represents how the energy contained in the signal is distributed as a function of frequency ω or f. Moreover, if $X(f)$ is used, the factor $1/2\pi$ in front of the inverse transform is dropped so that the transform pair takes a more symmetric form. On the other hand, as Fourier transform of discrete signal can be considered as a special case of $\mathcal{Z}$ transform when the real part of $s = \sigma + \mathrm{i}\omega$ is zero, i.e., $z = e^s = e^{\mathrm{i}\omega}$:

$$X(z)|_{z=e^{\mathrm{i}\omega}} = \sum_{n=-\infty}^{+\infty} x[n]z^{-n}|_{z=e^{\mathrm{i}\omega}} = \sum_{n=-\infty}^{+\infty} x[n]e^{-\mathrm{i}\omega n} = X(e^{\mathrm{i}\omega}) \tag{7.1.663}$$

it is also natural to denote the spectrum of $x[n]$ by $X(e^{\mathrm{i}\omega})$.

7.1.5.1.3 Properties of Discrete Fourier Transform

As a special case of general Fourier transform, the discrete time transform shares all properties (and their proofs) of the Fourier transform discussed above, except now some of these properties may take different forms. In the following, we always assume $\mathcal{F}[x[m]] = X(e^{\mathrm{i}\omega})$ and $\mathcal{F}[y[m]] = Y(e^{\mathrm{i}\omega})$.

P1. Linearity:

$$\mathcal{F}[ax[m] + by[m]] = aX(e^{\mathrm{i}\omega}) + bY(e^{\mathrm{i}\omega}) \tag{7.1.664}$$

P2. Time Shifting:

$$\mathcal{F}[x[m - m_0]] = e^{-\mathrm{i}m_0\omega}X(e^{\mathrm{i}\omega}) \tag{7.1.665}$$

Proof 7.3.21.

$$\mathcal{F}[x[m - m_0]] = \sum_{m=-\infty}^{+\infty} x[m - m_0]e^{-\mathrm{i}\omega m} \tag{7.1.666}$$

If we let $m' = m - m_0$, the above becomes:

$$\mathcal{F}[x[m - m_0]] = \sum_{m=-\infty}^{+\infty} x[m']e^{-\mathrm{i}\omega(m'+m_0)} = e^{-\mathrm{i}\omega m_0}X(e^{\mathrm{i}\omega}) \tag{7.1.667}$$

■ Q.E.D.

P3. Time Reversal:

$$\mathcal{F}[x[-m]] = X(e^{-\mathrm{i}\omega}) \tag{7.1.668}$$

P4. Frequency Shifting:

$$\mathcal{F}[x[m]e^{\mathrm{i}\omega_0 m}] = X(e^{\mathrm{i}(\omega-\omega_0)}) \tag{7.1.669}$$

P5. Differencing:

Differencing is the discrete-time counterpart of differentiation.

$$\mathcal{F}[x[m] - x[m-1]] = (1-e^{-\mathrm{i}\omega})X(e^{\mathrm{i}\omega}) \tag{7.1.670}$$

Proof 7.3.22.

$$\begin{aligned}\mathcal{F}[x[m]-x[m-1]] &= \mathcal{F}[x[m]] - \mathcal{F}[x[m-1]]\\ &= X(e^{\mathrm{i}\omega}) - X(e^{\mathrm{i}\omega})e^{-\mathrm{i}\omega} = (1-e^{-\mathrm{i}\omega})X(e^{\mathrm{i}\omega})\end{aligned} \tag{7.1.671}$$

■ Q.E.D.

P6. Differentiation in frequency:

$$\mathcal{F}^{-1}\left[\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}\omega}X(e^{\mathrm{i}\omega})\right] = m\,x[m] \tag{7.1.672}$$

Proof 7.3.23. Differentiating the definition of discrete Fourier transform with respect to ω, we get:

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}\omega}X(e^{\mathrm{i}\omega}) &= \frac{\mathrm{d}}{\mathrm{d}\omega}\sum_{m=-\infty}^{+\infty} x[m]e^{-\mathrm{i}\omega m} = \sum_{m=-\infty}^{+\infty} x[m]\frac{\mathrm{d}}{\mathrm{d}\omega}e^{-\mathrm{i}\omega m}\\ &= \sum_{m=-\infty}^{+\infty} -\mathrm{i}mx[m]e^{-\mathrm{i}\omega m}\end{aligned} \tag{7.1.673}$$

■ Q.E.D.

P7. Convolution Theorems:

The convolution theorem states that convolution in time domain corresponds to multiplication in frequency domain and vice versa:

$$\mathcal{F}[x[n]*y[n]] = X(e^{\mathrm{i}\omega})\,Y(e^{\mathrm{i}\omega}) \quad (a) \tag{7.1.674}$$

$$\mathcal{F}[x[n]\,y[n]] = X(e^{\mathrm{i}\omega}) * Y(e^{\mathrm{i}\omega}) \quad (b) \tag{7.1.675}$$

Recall that the convolution of periodic signals $x_T(t)$ and $y_T(t)$ is:

$$x_T(t)*y_T(t) \triangleq \frac{1}{T}\int\limits_T x_T(\tau)y_T(t-\tau)\mathrm{d}\tau \tag{7.1.676}$$

Here the convolution of periodic spectra $X(f)$ and $Y(f)$ is similarly defined as:

$$X(e^{\mathrm{i}\omega})*Y(e^{\mathrm{i}\omega})=\frac{1}{\Omega}\int\limits_{\Omega}X(e^{\mathrm{i}\omega'})Y(e^{\mathrm{i}(\omega-\omega')})\mathrm{d}\omega'=\frac{1}{2\pi}\int\limits_{0}^{2\pi}X(e^{\mathrm{i}\omega'})Y(e^{\mathrm{i}(\omega-\omega')})\mathrm{d}\omega' \quad (7.1.677)$$

Proof of (a):

$$\begin{aligned}\mathcal{F}[x[n]*y[n]]&=\sum_{n=-\infty}^{+\infty}\left[\sum_{m=-\infty}^{+\infty}x[m]y[n-m]\right]e^{-\mathrm{i}n\omega}\\&=\sum_{m=-\infty}^{+\infty}x[m]\left[\sum_{n=-\infty}^{+\infty}y[n-m]e^{-\mathrm{i}(n-m)\omega}\right]e^{-\mathrm{i}m\omega}\\&=X(\mathrm{i}\omega)\,Y(\mathrm{i}\omega)\end{aligned} \quad (7.1.678)$$

Proof of (b):

$$\begin{aligned}\mathcal{F}[x[n]y[n]]&=\sum_{n=-\infty}^{+\infty}x[n]y[n]e^{-\mathrm{i}n\omega}=\sum_{n=-\infty}^{+\infty}\left[\frac{1}{2\pi}\int\limits_{0}^{2\pi}X(\mathrm{i}\omega')e^{\mathrm{i}n\omega'}\mathrm{d}\omega'\right]y[n]e^{-\mathrm{i}n\omega}\\&=\frac{1}{2\pi}\int\limits_{0}^{2\pi}X(\mathrm{i}\omega')\left[\sum_{n=-\infty}^{+\infty}e^{\mathrm{i}n\omega'}y[n]e^{-\mathrm{i}n\omega}\right]\mathrm{d}\omega'\\&=\frac{1}{2\pi}\int\limits_{0}^{2\pi}X(\mathrm{i}\omega')\sum_{n=-\infty}^{+\infty}y[n]e^{-\mathrm{i}n(\omega-\omega')}\mathrm{d}\omega'\\&=\frac{1}{2\pi}\int\limits_{0}^{2\pi}X(\mathrm{i}\omega')Y(\mathrm{i}(\omega-\omega'))\mathrm{d}\omega'=X(\mathrm{i}\omega)*Y(\mathrm{i}\omega)\end{aligned} \quad (7.1.679)$$

■ Q.E.D.

P8. Parseval's relation for the discrete Fourier transform:

$$\sum_{n=-\infty}^{+\infty}|x[n]|^2=\frac{1}{2\pi}\int\limits_{0}^{2\pi}|X(e^{\mathrm{i}\omega})|^2\mathrm{d}\omega \quad (7.1.680)$$

✍**Examples:**

E1. The discrete Fourier transform of the Dirac delta:

$$\mathcal{F}[\delta[n]]=\sum_{n=-\infty}^{+\infty}\delta[n]e^{-\mathrm{i}\omega n}=1 \quad (7.1.681)$$

E2. The spectrum of:

$$x[n]=a^n u[n]\quad(|a|<1) \quad (7.1.682)$$

is:

$$X(e^{\mathrm{i}\omega})=\mathcal{F}[x[n]]=\sum_{n=-\infty}^{+\infty}a^n u[n]e^{-\mathrm{i}n\omega}=\sum_{n=0}^{+\infty}(ae^{-\mathrm{i}\omega})^n=\frac{1}{1-ae^{-\mathrm{i}\omega}}\tag{7.1.683}$$

If the signal is two-sided:

$$x[n]=a^{|n|}=a^n u[n]+a^{-n}u[-n]-\delta[n],\quad (|a|<1)\tag{7.1.684}$$

Due to the time reversal property, its spectrum is:

$$X(e^{\mathrm{i}\omega})=\frac{1}{1-ae^{-\mathrm{i}\omega}}+\frac{1}{1-ae^{\mathrm{i}\omega}}-1=\frac{1-a^2}{1-2a\,\cos(\omega)+a^2}\tag{7.1.685}$$

E3. Consider a LTI system (Linear Time-Invariant) with impulse response:

$$h[n]=a^n u[n],\quad (|a|<1)\tag{7.1.686}$$

and input:

$$x[n]=b^n u[n],\quad (|b|<1)\tag{7.1.687}$$

The output $y[n]$ can be found in either time domain by convolution or in frequency domain by multiplication. In time domain, we have:

$$\begin{aligned}y[n]&=h[n]*x[n]=\sum_{m=-\infty}^{+\infty}a^{n-m}u[n-m]b^m u[m]=a^n\sum_{m=0}^{n}a^{-m}b^m\\&=a^n\frac{1-(b/a)^{n+1}}{1-(b/a)}u[n]=\frac{1}{a-b}(a^{n+1}-b^{n+1})u[n]\end{aligned}\tag{7.1.688}$$

When $a=b$, we have:

$$y[n]=a^n\sum_{m=0}^{n}a^{-m}b^m=(n+1)a^n u[n]\tag{7.1.689}$$

In frequency domain, we first find the spectra of both $x[n]$ and $h[n]$ to be:

$$X(e^{\mathrm{i}\omega})=\frac{1}{1-ae^{-\mathrm{i}\omega}};\quad H(e^{\mathrm{i}\omega})=\frac{1}{1-be^{-\mathrm{i}\omega}}\tag{7.1.690}$$

and the spectrum of the output is:

$$Y(e^{\mathrm{i}\omega})=H(e^{\mathrm{i}\omega})\,X(e^{\mathrm{i}\omega})=\frac{1}{(1-be^{-\mathrm{i}\omega})(1-ae^{-\mathrm{i}\omega})}\tag{7.1.691}$$

To find $y(n)$ in time domain by inverse transform of $Y(e^{\mathrm{i}\omega})$, we use partial fraction expansion to rewrite the above as:

$$Y(e^{\mathrm{i}\omega})=\frac{A}{1-ae^{-\mathrm{i}\omega}}+\frac{B}{1-be^{-\mathrm{i}\omega}}=\frac{A-Abe^{-\mathrm{i}\omega}+B-aBe^{-\mathrm{i}\omega}}{(1-be^{-\mathrm{i}\omega})(1-ae^{-\mathrm{i}\omega})}\tag{7.1.692}$$

By equating the coefficients of $e^{-\mathrm{i}\omega}$ and the constants, we get:

$$A+B=1,\quad aB+bA=0 \tag{7.1.693}$$

which can be solved to get:

$$A=\frac{a}{a-b},\qquad B=\frac{-b}{a-b} \tag{7.1.694}$$

In this form, $Y(\mathrm{i}\omega)$ can be easily inverse transformed to yield:

$$h[n]=\left[\frac{a}{a-b}a^n-\frac{b}{a-b}b^n\right]u[n]=\frac{1}{a-b}(a^{n+1}-b^{n+1})u[n] \tag{7.1.695}$$

same as the result from convolution. Again when $a=b$, we have:

$$Y(e^{\mathrm{i}\omega})=\frac{1}{(1-ae^{-\mathrm{i}\omega})^2}=\frac{e^{\mathrm{i}\omega}}{a}\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}\omega}\left(\frac{1}{1-ae^{-\mathrm{i}\omega}}\right) \tag{7.1.696}$$

But since:

$$\mathcal{F}^{-1}\left[\frac{1}{1-ae^{-\mathrm{i}\omega}}\right]=a^n u[n] \tag{7.1.697}$$

by the frequency differentiation property, we have:

$$\mathcal{F}^{-1}\left[\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}\omega}\left(\frac{1}{1-ae^{-\mathrm{i}\omega}}\right)\right]=na^n u[n] \tag{7.1.698}$$

and the output in time domain is obtained as:

$$\begin{aligned}y[n]&=\mathcal{F}^{-1}[Y(e^{\mathrm{i}\omega})]=\mathcal{F}^{-1}\left[\frac{e^{\mathrm{i}\omega}}{a}\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}\omega}\left(\frac{1}{1-ae^{-\mathrm{i}\omega}}\right)\right]\\&=\frac{1}{a}(n+1)a^{n+1}u[n+1]=(n+1)a^n u[n+1]=(n+1)a^n u[n]\end{aligned} \tag{7.1.699}$$

Note that the time-shifting property is used due to the factor $e^{\mathrm{i}\omega}$. Also note that $u[n+1]$ (starting at $n=-1$) is replaced by $u[n]$ (starting at $n=0$) as $n+1=0$ when $n=-1$.

E4. The impulse response of a discrete LTI system is:

$$h[m]=a^m u[m] \tag{7.1.700}$$

where $|a|<1$ so that the system is stable. The output $y[m]$ of the system with an input:

$$x[m]=\cos\left(\frac{2\pi m}{N}\right)=\frac{e^{\mathrm{i}2\pi m/N}+e^{-\mathrm{i}2\pi m/N}}{2} \tag{7.1.701}$$

can be found in three different ways:

- Time domain convolution:

  The output is the convolution of $x[m]$ and $h[m]$:

$$\begin{aligned} y[m] = h[m] * x[m] &= \sum_{k=0}^{+\infty} a^k \frac{e^{i2\pi(m-k)/N} + e^{-i2\pi(m-k)/N}}{2} \\ &= \frac{1}{2} e^{i2\pi m/N} \sum_{k=0}^{+\infty} a^k e^{-i2\pi k/N} + \frac{1}{2} e^{-i2\pi m/N} \sum_{k=0}^{+\infty} a^k e^{i2\pi k/N} \\ &= \frac{1}{2} e^{i2\pi m/N} \frac{1}{1-ae^{-i2\pi/N}} + \frac{1}{2} e^{-i2\pi m/N} \frac{1}{1-ae^{i2\pi/N}} \end{aligned} \tag{7.1.702}$$

- The eigenequation method:

  We first get the frequency response function from $h[m]$:

$$H(e^{i\omega}) = \sum_{k=-\infty}^{+\infty} h[k] e^{-i\omega k} = \sum_{k=0}^{+\infty} (ae^{-i\omega})^k = \frac{1}{1-ae^{-i\omega}} \tag{7.1.703}$$

  which is the eigenvalue of the system when the input is a complex exponential $e^{in\omega}$. Now the system's response to:

$$x[m] = \cos\left(\frac{2\pi m}{N}\right) = \frac{e^{i2\pi m/N} + e^{-i2\pi m/N}}{2} \tag{7.1.704}$$

  can be found to be:

$$\begin{aligned} y[m] &= \frac{1}{2}\left[H(e^{i2\pi/N}) e^{i2\pi m/N} + H(e^{-i2\pi/N}) e^{-i2\pi m/N}\right] \\ &= \frac{1}{2} e^{i2\pi m/N} \frac{1}{1-ae^{-i2\pi/N}} + \frac{1}{2} e^{-i2\pi m/N} \frac{1}{1-ae^{i2\pi/N}} \end{aligned} \tag{7.1.705}$$

- Frequency domain multiplication:

  If we find the spectra of both $h[m]$ and $x[m]$ in the frequency domain, the spectrum of $y[m]$ can be found by multiplication. We already know:

$$H(e^{i\omega}) = \mathcal{F}[h[m]] = \frac{1}{1-ae^{-i\omega}} \tag{7.1.706}$$

  We next find the spectrum of $x[m]$:

$$\begin{aligned} X(e^{i\omega}) = \mathcal{F}[x[m]] &= \sum_{m=-\infty}^{+\infty} \frac{e^{i2\pi m/N} + e^{-i2\pi m/N}}{2} e^{-im\omega} \\ &= \pi \sum_{k=-\infty}^{+\infty} [\delta(\omega - 2k\pi - 2\pi/N) + \delta(\omega - 2k\pi - 2\pi/N)] \end{aligned} \tag{7.1.707}$$

  Now the spectrum of the output $y[m]$ can be found:

$$\begin{aligned} Y(e^{i\omega}) &= H(e^{i\omega}) X(e^{i\omega}) \\ &= \frac{\pi}{1-ae^{-i\omega}} \sum_{k=-\infty}^{+\infty} [\delta(\omega - 2k\pi - 2\pi/N) + \delta(\omega - 2k\pi - 2\pi/N)] \end{aligned} \tag{7.1.708}$$

and the output $y[m]$ is obtained by inverse Fourier transform:

$$\begin{aligned} y[m] &= \frac{1}{2\pi}\int\limits_0^{2\pi}\left[\frac{\pi}{1-ae^{-\mathrm{i}\omega}}\sum_{k=-\infty}^{+\infty}\left[\delta\left(\omega-2k\pi-\frac{2\pi}{N}\right)+\delta\left(\omega-2k\pi-\frac{2\pi}{N}\right)\right]\right]e^{\mathrm{i}m\omega}\mathrm{d}\omega \\ &= \frac{1}{2}e^{\mathrm{i}2\pi m/N}\frac{1}{1-ae^{-\mathrm{i}2\pi/N}}+\frac{1}{2}e^{-\mathrm{i}2\pi m/N}\frac{1}{1-ae^{\mathrm{i}2\pi/N}} \end{aligned}$$

The physical meaning of this result will be clear if we write $H(2\pi/N)$ in polar form:

$$H(e^{\mathrm{i}2\pi/N})=\frac{1}{1-ae^{\mathrm{i}2\pi/N}}=re^{\mathrm{i}\theta} \tag{7.1.709}$$

and the output becomes:

$$y[m]=r\cos\left(\frac{2\pi}{N}m+\theta\right) \tag{7.1.710}$$

That is, the output of the system is also a sinusoidal signal of the same frequency as the input, but with different magnitude r and a phase angle θ. For example, if $N=4$, we have:

$$H(e^{\mathrm{i}\pi/2})=\frac{1}{1+\mathrm{i}a}=\frac{1}{\sqrt{1+a^2}}e^{-\mathrm{i}\tan^{-1}(a)} \tag{7.1.711}$$

and the output is:

$$y[m]=\frac{1}{\sqrt{1+a^2}}\cos\left(\frac{\pi m}{2}-\tan^{-1}(a)\right) \tag{7.1.712}$$

7.1.5.2 Laplace Transform

The Laplace transform (LT), as we have already mention it, is a generalization of the Fourier transform (TF), however, although it is so called in his honour because he used it in his work on the theory of probability, seems to have been originally discovered by Leonhard Euler. The Laplace transform also appears in all branches of mathematical physics (mechanical engineering, electronics, quantitative finance, etc.) and is used extensively in order to solve differential equations that arise in many modelling situations of real life.

As for the Fourier transform, the Laplace transformation allows us to get rid of differentiations. The transform can do this because it has the wonderful property of converting the operation of differentiation into the far simpler one of multiplication. That is, it transforms a differential equation into an algebraic equation. This process is analogous to how logarithms transform multiplication into the simpler operation of addition (because $\log(xy)=\log(x)+\log(y)$).

A power series about an origin is any series that can be written in the following form:

$$\sum_{n=0}^{+\infty} a_n x^n \tag{7.1.713}$$

where a_n are numbers and n is a non-negative integer. One can think of $a_n=a(n)$ as a function of n for each non-negative integer $n=0,1,2,\ldots$. In order to give birth to Laplace transformation technique, we make some associations. The discrete variable n is converted into a real variable t. The coefficient term a_n is written as $f(t)$. The term x^n can equivalently be written as $e^{(\ln(x^t))}$. Finally, summation notation can be replaced by its continuous analogue, that is, integration. By doing so, we have following:

$$\sum_{n=0}^{+\infty} a_n x^n \rightsquigarrow \int\limits_0^{+\infty} f(t)e^{\ln(x^t)}\,\mathrm{d}t \tag{7.1.714}$$

For convergence, it is obviously important to have following condition for the above integral (yes think for this about the original sum!):

$$\sum_{n=0}^{+\infty} a_n x^n \rightsquigarrow \int\limits_0^{+\infty} f(t)e^{\ln(x^t)}\mathrm{d}t; \qquad 0<x<1 \tag{7.1.715}$$

Therefore:

$$\sum_{n=0}^{+\infty} a_n x^n \rightsquigarrow \int\limits_0^{+\infty} f(t)e^{t\ln(x)}\mathrm{d}t \tag{7.1.716}$$

Since $0<x<1$ so it implies that:

$$\ln(0)<\ln(x)<\ln(1) \quad \text{or} \quad -\infty<\ln(x)<0 \tag{7.1.717}$$

Thus $\ln(x)$ has to be negative for the integral to converge, in this regard, we suppose $\ln(x)=-s$ where $s>0$. Thus, the final integral takes the form:

$$\sum_{n=0}^{+\infty} a_n x^n \rightsquigarrow \int\limits_0^{+\infty} f(t)e^{-st}\mathrm{d}t=F(s) \quad s>0 \tag{7.1.718}$$

In this way, we can say that Laplace Transform is simply stretching a discrete (infinite series) into a continuous (integration) analogue.

Let us recall that if $s=\mathrm{i}\omega$ (the real part of s is purely imaginary), Laplace transform becomes Fourier transform! In general, any continuous time signal $x(t)$ can be Laplace transformed to get:

$$\boxed{X(s)=\mathcal{L}(x(t))\triangleq\int\limits_{-\infty}^{+\infty}x(t)e^{-st}\mathrm{d}t} \tag{7.1.719}$$

provided the integral converges, i.e., the function $X(s)$ exists. This general form of "bilateral Laplace transform" is related to the Fourier transform:

$$\mathcal{L}(x(t))=\int\limits_{-\infty}^{+\infty}x(t)e^{-(\sigma+\mathrm{i}\omega)t}\mathrm{d}t=\int\limits_{-\infty}^{+\infty}[x(t)e^{-\sigma t}]e^{-\mathrm{i}\omega t}\mathrm{d}t=\mathcal{F}[x(t)e^{-\sigma t}] \tag{7.1.720}$$

i.e., Laplace transform of a generic function is Fourier transform of the same function multiplied by $e^{-\sigma t}$. This exponential factor has the effect of forcing the signals to converge. This is why the Laplace transform can be applied to a broader class of signals than the Fourier transform, including exponentially growing signals shown in the following two cases:

- Right sided:

  $$x(t)=e^{at}u(t),\quad (a>0) \tag{7.1.721}$$

  The Fourier transform does not exist as the signal grows exponentially when $t\rightarrow+\infty$, i.e., the transform integral does not converge (not integrable). However, its Laplace transform exists if $\Re[s]=\sigma>a$ (i.e., $\sigma-a>0$), as the modified signal $x(t)e^{-\sigma t}=e^{-(\sigma-a)t}u(t)$ will converge.

- Left sided:

  $$x(t)=e^{at}u(-t),\quad (a<0) \tag{7.1.722}$$

  Again the Fourier transform does not exist as the signal grows exponentially when $t\rightarrow-\infty$, i.e., the transform integral does not converge. But if $\Re[s]=\sigma<a$ (i.e., $\sigma-a<0$), the modified signal $x(t)e^{-\sigma t}=e^{-(\sigma-a)t}u(-t)$ will converge and its Laplace transform exists.

In Fourier transform, both the signal $x(t)$ in time domain and its spectrum $X(\mathrm{i}\omega)$ in frequency domain are a one-dimensional (1D) complex function. However, the Laplace transform $X(s)$ of the 1D signal $x(t)$ is a complex function defined over a two-dimensional *complex plane*, named the "s-plane", spanned by the two variables σ (for the horizontal real axis) and ω (for the vertical imaginary axis).

In particular, if this 2D function $X(s)=X(\sigma+\mathrm{i}\omega)$ is evaluated along the imaginary axis $\Re[s]=\sigma=0$, it becomes a 1D function $X(\mathrm{i}\omega)$, the Fourier transform of $x(t)$. Graphically, the Fourier transform, the spectrum of the signal, can be found as the cross section of the 2D function $X(s)=X(\sigma+\mathrm{i}\omega)$ along the line $\Re[s]=\sigma=0$.

Before we go further another way to introduce the Laplace transform may be useful and help the reader. But if you have understand the above introduction you can go over this alternate presentation.

The Fourier transform works quite well only when the argument of the integral does not diverge, where the kernel (the multiplication by $e^{-\mathrm{i}\omega t}$) is purely complex, and its integral sweeps the set of reals (bilateral infinity $]-\infty,+\infty[$).

Typically, mathematicians, that like to generalize stuff...., have generalized the Fourier transform to functions kernel that are not purely imaginary and whose integral could be one-sided $[0,+\infty[$. Thus, the Laplace transform converges for a larger set of functions than the Fourier transform.

Indeed, let us see a simple example with a diverging function:

$$\mathcal{F}(e^t)(\omega)=\int\limits_{-\infty}^{+\infty} e^t e^{-\mathrm{i}\omega t}\mathrm{d}t=\int\limits_{-\infty}^{+\infty} e^{t-\mathrm{i}\omega t}\mathrm{d}t=\int\limits_{-\infty}^{+\infty} e^{(1-\mathrm{i}\omega)t}\mathrm{d}t=\left.\frac{e^{\alpha t}}{\alpha}\right|_{-\infty}^{+\infty}=+\infty \tag{7.1.723}$$

This last integral does not converge (at least as far as I know ...) whatever the value of α different from zero!

We can define a generalized version of the Fourier transform and denote it (we already know that it is the bilateral Laplace transform):

$$\mathcal{L}(f(t))(s)=\int\limits_{-\infty}^{+\infty} f(t)e^{-st}\mathrm{d}t \tag{7.1.724}$$

with (we already know this!):

$$s=\sigma+\mathrm{i}\omega t \tag{7.1.725}$$

where, in general, the convergence of the integral is not guaranteed for all s. We then name "abscissa of absolute convergence" of the Laplace transform the set of values that σ must take for the integral to converge.

Let's revisit the non-convergent Fourier transform seen just above, but where the function is defined only for positive times (one-sided Laplace transform):

$$\mathcal{L}(e^t)(s)=\int\limits_{-\infty}^{+\infty} e^t e^{-st}\mathrm{d}t=\int\limits_{0}^{+\infty} e^t e^{-st}\mathrm{d}t=\int\limits_{0}^{+\infty} e^t e^{-(\sigma+\mathrm{i}\omega)t}\mathrm{d}t=\int\limits_{0}^{+\infty} e^{-((\sigma-1)+\mathrm{i}\omega)t}\mathrm{d}t=\left.\frac{e^{-t((\sigma-1)+\mathrm{i}\omega)}}{-((\sigma-1)+\mathrm{i}\omega)}\right|_{0}^{+\infty} \tag{7.1.726}$$

The result converges if $\omega\geq 0$ (which is always the case in physics) for $t>0$ and if and only if

$\sigma > 1$. Then in this case we have:

$$\begin{aligned}\mathcal{L}(e^t)(s) &= \left.\frac{e^{-t((\sigma-1)+\mathrm{i}\omega)}}{-((\sigma-1)+\mathrm{i}\omega)}\right|_0^{+\infty} = \left.\frac{e^{(1-\sigma)t}e^{-\mathrm{i}\omega t}}{-((\sigma-1)+\mathrm{i}\omega)}\right|_0^{+\infty} = \frac{\underbrace{e^{(1-\sigma)\cdot+\infty}}_{\to 0}\underbrace{e^{-\mathrm{i}\omega\cdot+\infty}}_{\to 0}}{-((\sigma-1)+\mathrm{i}\omega)} - \frac{e^{(1-\sigma)\cdot 0}e^{-\mathrm{i}\omega\cdot 0}}{-((\sigma-1)+\mathrm{i}\omega)}\\ &= 0 - \frac{1}{-((\sigma-1)+\mathrm{i}\omega)} = \frac{1}{(\sigma+\mathrm{i}\omega)-1} = \frac{1}{s-1}\end{aligned} \tag{7.1.727}$$

7.1.5.2.1 Inverse Laplace Transform

The inverse Laplace transform can be obtained from the corresponding Fourier transform:

$$X(s) = X(\sigma+\mathrm{i}\omega) = \mathcal{L}(x(t)) = \int\limits_{-\infty}^{+\infty} x(t)e^{-(\sigma+\mathrm{i}\omega)t}\mathrm{d}t = \mathcal{F}(x(t)e^{-\sigma t}) \tag{7.1.728}$$

The inverse Fourier transform of the above is:

$$x(t)e^{-\sigma t} = \mathcal{F}^{-1}(X(\sigma+\mathrm{i}\omega)) = \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\sigma+\mathrm{i}\omega)e^{\mathrm{i}\omega t}\mathrm{d}\omega \tag{7.1.729}$$

Multiplying both sides by $e^{\sigma t}$, we get the inverse Laplace transform:

$$x(t) = \mathcal{L}^{-1}[X(s)] = \frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} X(\sigma+\mathrm{i}\omega)e^{(\sigma+\mathrm{i}\omega)t}\mathrm{d}\omega \tag{7.1.730}$$

As we want to represent the inverse transform in terms of s (instead of ω), we realize that:

$$\mathrm{d}s = \mathrm{d}(\sigma+\mathrm{i}\omega) = \mathrm{i}\,\mathrm{d}\omega, \quad \text{ie,} \quad \mathrm{d}\omega = \frac{\mathrm{d}s}{\mathrm{i}} \tag{7.1.731}$$

We also realize that the integral in the inverse transform is along a vertical line in the s-plane from $\mathrm{i}\omega = -\mathrm{i}\infty$ to $\mathrm{i}\omega = +\mathrm{i}\infty$ while the other variable σ is fixed. The "inverse Laplace transform" above can therefore be written as:

$$\boxed{x(t) = \mathcal{L}^{-1}(X(s)) = \frac{1}{\mathrm{i}2\pi}\int\limits_{\sigma-\mathrm{i}\infty}^{\sigma+\mathrm{i}\infty} X(s)e^{st}\mathrm{d}s} \tag{7.1.732}$$

Now we have the Laplace transform pair:

$$X(s) = \mathcal{L}(x(t)) = \int\limits_{-\infty}^{+\infty} x(t)e^{-st}\mathrm{d}t \tag{7.1.733}$$

$$x(t) = \mathcal{L}^{-1}(X(s)) = \frac{1}{\mathrm{i}2\pi}\int\limits_{\sigma-\mathrm{i}\infty}^{\sigma+\mathrm{i}\infty} X(s)e^{st}\mathrm{d}s \tag{7.1.734}$$

The forward (bilateral) and inverse Laplace transform pair can also be represented as:

$$x(t) \xleftrightarrow{\mathcal{L}} X(s) \tag{7.1.735}$$

7.1.5.2.2 Region of Convergence

An essential issue of Laplace transform of $x(t)$ is whether the transform $X(s)$ even exists, and under what condition it exists. To see this, consider the following examples.

✍**Examples:**

E1. The Fourier transform of a signal $x(t)=e^{-at}u(t)$ is:

$$X(\mathrm{i}\omega)=\int\limits_{-\infty}^{+\infty} e^{-at}u(t)e^{-\mathrm{i}\omega t}\mathrm{d}t=\int\limits_{0}^{+\infty} e^{-(a+\mathrm{i}\omega)t}\mathrm{d}t=-\frac{1}{a+\mathrm{i}\omega}e^{-(a+\mathrm{i}\omega)}|_0^{+\infty} \tag{7.1.736}$$

This integral does not converge unless $a>0$. In other words, only when the signal $x(t)$ decays (instead of grows) exponentially, will its Fourier transform $X(\mathrm{i}\omega)$ exist:

$$X(\mathrm{i}\omega)=\frac{1}{a+\mathrm{i}\omega}\quad a<0 \tag{7.1.737}$$

Now consider the Laplace transform of the same signal:

$$X(s)=\int\limits_{0}^{+\infty} e^{-at}e^{-st}\mathrm{d}t=\int\limits_{0}^{+\infty} e^{-at}e^{-(\sigma+\mathrm{i}\omega)t}\mathrm{d}t=\int\limits_{0}^{+\infty} e^{-(a+\sigma)t}e^{-\mathrm{i}\omega t}\mathrm{d}t \tag{7.1.738}$$

Similar to the Fourier transform, for this integral to converge, i.e., for Laplace transform $X(s)$ to exist, it is necessary for $\sigma=\Re[s]$ to satisfy:

$$a+\sigma>0\quad\text{or}\quad\Re[s]=\sigma>-a \tag{7.1.739}$$

in which case the Laplace transform is:

$$X(s)=\frac{1}{(\sigma+a)+\mathrm{i}\omega}=\frac{1}{s+a}\quad\Re[s]>-a \tag{7.1.740}$$

As a special case where $a=0$, $x(t)=u(t)$ we have:

$$\mathcal{L}(u(t))=\frac{1}{s}\quad\Re[s]>0 \tag{7.1.741}$$

When $\Re[s]=\sigma=0$, the Laplace transform $X(s)$ becomes Fourier transform $X(\mathrm{i}\omega)$.

E2. The non-causal version of the signal above is $x(t)=-e^{-at}u(-t)$ and its Laplace transform is:

$$X(s)=-\int\limits_{-\infty}^{0} e^{-at}e^{-st}\mathrm{d}t=-\int\limits_{-\infty}^{0} e^{-((a+\sigma)+\mathrm{i}\omega)t}\mathrm{d}t=\frac{1}{a+\sigma+\mathrm{i}\omega}e^{-((a+\sigma)+\mathrm{i}\omega)t}|_{-\infty}^{0} \tag{7.1.742}$$

Only when:

$$a+\sigma<0\quad\text{or}\quad\Re[s]=\sigma<-a \tag{7.1.743}$$

will this integral converge and Laplace transform $X(s)$ exists:

$$X(s)=\frac{1}{a+\sigma+\mathrm{i}\omega}=\frac{1}{a+s} \quad \Re[s]<-a \tag{7.1.744}$$

Again as a special case when $a=0$, $x(t)=-u(-t)$ we have:

$$\mathcal{L}[-u(-t)]=\frac{1}{s} \quad \Re[s]<0 \tag{7.1.745}$$

Comparing the two examples above we see that two different signals can have identical Laplace transform $X(s)$ but s may have to satisfy different conditions for $X(s)$ to exist. In general, the set of all s values satisfying the conditions for the integral of Laplace transform to converge is called the "region of convergence" (ROC) in the complex s-plane. In the first case above, the ROC is $\Re[s]>0$, and in the second case, the ROC is $\Re[s]<0$.

E3. Consider the signal:

$$x(t)=\left[e^{-2t}+e^{t}\cos(3t)\right]u(t)=\left[e^{-2t}+\frac{1}{2}e^{-(1-\mathrm{i}3)t}+\frac{1}{2}e^{-(1+\mathrm{i}3)t}\right]u(0) \tag{7.1.746}$$

The Laplace transform of this signal is:

$$\begin{aligned}X(s)&=\int\limits_0^{+\infty}\left[e^{-2t}+\frac{1}{2}e^{-(1-\mathrm{i}3)t}+\frac{1}{2}e^{-(1+\mathrm{i}3)t}\right]e^{-st}\mathrm{d}t\\&=\int\limits_0^{+\infty}e^{-2t}e^{-st}\mathrm{d}t+\frac{1}{2}\int\limits_0^{+\infty}e^{-(1-\mathrm{i}3)t}e^{-st}\mathrm{d}t+\frac{1}{2}\int\limits_0^{+\infty}e^{-(1+\mathrm{i}3)t}e^{-st}\mathrm{d}t\\&=\frac{1}{s+2}+\frac{1/2}{s+(1-\mathrm{i}3)}+\frac{1/2}{s+(1+\mathrm{i}3)}\end{aligned} \tag{7.1.747}$$

Following example 1, we see that the conditions for the three integrals to converge are, respectively:

$$\Re[s]>-2,\quad \Re[s]>-1,\quad \Re[s]>-1 \tag{7.1.748}$$

i.e., when $\Re[s]>-1$, $X(s)$ exists and can be written as:

$$X(s)=\frac{1}{s+2}+\frac{1/2}{s+(1-\mathrm{i}3)}+\frac{1/2}{s+(1+\mathrm{i}3)}=\frac{2s^2+5s+12}{(s^2+2s+10)(s+2)} \quad \Re[s]>-1 \tag{7.1.749}$$

E4. Let us consider:

$$\mathcal{L}(\delta(t-T))=\int\limits_{-\infty}^{+\infty}\delta(t)e^{-st}\mathrm{d}t=e^{-sT} \tag{7.1.750}$$

As the Laplace integration converges independently of s, the ROC is the entire s-plane. In particular, when $T=0$, we have:

$$\mathcal{L}(\delta(t))=1 \tag{7.1.751}$$

7.1.5.2.3 Zeros and Poles of Laplace Transform

All Laplace transforms in the above examples are rational, i.e., they can be written as a ratio of polynomials of variable s in the general form:

$$X(s) = \frac{N(s)}{D(s)} = \frac{\sum_{k=0}^{M} b_k s^k}{\sum_{k=0}^{N} a_k s^k} = \frac{\prod_{k=1}^{M} (s - s_{z_k})}{\prod_{k=1}^{N} (s - s_{p_k})} \tag{7.1.752}$$

where $N(s)$ is the numerator polynomial of order M with roots $s_{z_k}, (k = 1, 2, \cdots, M)$, and $D(s)$ is the denominator polynomial of order N with roots $s_{p_k}, (k = 1, 2, \cdots, N)$. In general, we assume the order of the numerator polynomial is lower than that of the denominator polynomial, i.e., $M < N$. If this is not the case, we can always expand $X(s)$ into multiple terms so that $M < N$ is true for each of terms.

✍**Example:**

Consider:

$$X(s) = \frac{s^2 - 3}{s + 2} \tag{7.1.753}$$

As the order of the numerator $M = 2$ is higher than that of the denominator $N = 1$, we expand it into the following terms:

$$X(s) = \frac{s^2 - 3}{s + 2} = A + Bs + \frac{C}{s + 2} \tag{7.1.754}$$

and get:

$$s^2 - 3 = (A + Bs)(s + 2) + C = Bs^2 + (A + 2B)s + (2A + C) \tag{7.1.755}$$

Equating the coefficients for terms s^k $(k = 0, 1, \ldots, M)$ on both sides, we get:

$$B = 1, \quad A + 2B = 0, \quad 2A + C = -3 \tag{7.1.756}$$

Solving this system of equations, we get the following coefficients:

$$A = -2; \quad B = 1, \quad C = 1 \tag{7.1.757}$$

and:

$$X(s) = s - 2 + \frac{1}{s + 2} \tag{7.1.758}$$

Alternatively, the same result can be obtained by carrying out a long-hand division:

$$(s^2 - 3) \div (s + 2) \tag{7.1.759}$$

Definitions (#7.1.284):

D1. Any complex value s_z of s for which $H(s)|_{s=s_z}=H(s_z)=0$ is a "zero" of $H(s)$.

D2. Any complex value s_p of s for which $H(s)|_{s=s_p}=H(s_p)=\infty$ is a "pole" of $H(s)$.

Obviously, all roots of the numerator polynomial $N(s)$ are zeros of $H(s)$ and all roots of the denominator polynomial $D(s)$ are poles of $H(s)$. Moreover, if the order of $D(s)$ exceeds the order of $N(s)$ (i.e., $N>M$), then $H(\infty)=0$, i.e., there is a zero at infinity. On the other hand, if the order of $N(s)$ exceeds that of $D(s)$ (i.e., $M>N$), then $H(\infty)=\infty$, i.e, there is a pole at infinity. On the s-plane zeros and poles can be indicated by o and x respectively. Most essential behaviour properties of a LTI system can be obtained graphically from the ROC and the zeros and poles of its transfer function $H(s)$ on the s-plane.

7.1.5.2.4 Properties of region of convergence

Whether the Laplace transform $X(s)$ of a function $x(t)$ exists depends on whether or not the transform integral converges:

$$X(s)=\int\limits_{-\infty}^{+\infty}x(t)e^{-st}\mathrm{d}t=\int\limits_{-\infty}^{+\infty}x(t)e^{-\sigma t}e^{-\mathrm{i}\omega t}\mathrm{d}t<\infty \tag{7.1.760}$$

which in turn depends on the duration and magnitude of $x(t)$ as well as the real part of s $\Re[s]=\sigma$. When $x(t)$ is right sided (i.e., $x(t)=0$ for $t<t_0$), it may have infinite duration for $t>0$, and the larger σ the more quickly $x(t)e^{-\sigma t}$ decays as $t\rightarrow+\infty$. On the other hand, if $x(t)$ is left sided (i.e., $x(t)$ for $t<t_0$), it may have infinite duration for $t<0$, and the smaller σ the more quickly $x(t)e^{-\sigma t}$ decays as $t\rightarrow-\infty$. The imaginary part of s $\Im[s]=\mathrm{i}\omega$ determines the frequency of a sinusoid which is bounded and has no effect on the convergence of the integral. Based on these observations, we can get the following properties for the ROC:

- If $x(t)$ is absolutely integrable and of finite duration, then the ROC is the entire s-plane (the Laplace transform integral is finite, i.e., $X(s)$ exists, for any s).
- The ROC of $X(s)$ consists of strips parallel to the $\mathrm{i}\omega$-axis in the s-plane.
- If $x(t)$ is right sided and $\Re[s]=\sigma_0$ is in the ROC, then any s to the right of σ_0 (i.e., $\Re[s]>\sigma_0$) is also in the ROC, i.e., ROC is a right sided half plane.
- If $x(t)$ is left sided and $\Re[s]=\sigma_0$ is in the ROC, then any s to the left of σ_0 (i.e., $\Re[s]<\sigma_0$) is also in the ROC, i.e., ROC is a left sided half plane.
- If $x(t)$ is two-sided, then the ROC is the intersection of the two one-sided ROCs corresponding to the two one-sided parts of $x(t)$. This intersection can be either a vertical strip or an empty set.
- If $X(s)$ is rational, then its ROC does not contain any poles (by definition $X(s)|_{s=s_p}=\infty$ does not exist). The ROC is bounded by the poles or extends to infinity.
- If $X(s)$ is a rational Laplace transform of a right sided function $x(t)$, then the ROC is the half plane to the right of the rightmost pole, and if $X(s)$ is a rational Laplace transform of a left sided function $x(t)$, then the ROC is the half plane to the left of the leftmost pole.

- A signal $x(t)$ is absolutely integrable, i.e., its Fourier transform $X(\mathrm{i}\omega)$ exists, if and only if the ROC of the corresponding Laplace transform $X(s)$ contains the imaginary axis $\Re[s]=0$ or $s=\mathrm{i}\omega$.

✍**Examples:**

E1. Consider the Laplace transform of a two-sided signal $x(t)=e^{-b|t|}$:

$$X(s)=\mathcal{L}(x(t))=\mathcal{L}(e^{-b|t|})=\mathcal{L}(e^{-bt}u(t))+\mathcal{L}(e^{bt}u(-t)) \qquad (7.1.761)$$

The Laplace transform of the two components can be obtained from the two examples discussed earlier above. Then we get:

$$\mathcal{L}(e^{-bt}u(t))=\frac{1}{s+b} \quad \Re[s]>-b \qquad (7.1.762)$$

and let $b=-a$, we then have:

$$\mathcal{L}(e^{bt}u(-t))=\mathcal{L}(e^{-at}u(-t))=-\frac{1}{s+a}=-\frac{1}{s-b} \quad \Re[s]<-a=b \qquad (7.1.763)$$

Combining the two components, we have:

$$\mathcal{L}(e^{-b|t|})=\frac{1}{s+b}-\frac{1}{s-b}=\frac{-2b}{s^2-b^2} \quad -b<\Re[s]<b \qquad (7.1.764)$$

Whether $X(s)$ exists or not depends on b. If $b>0$, i.e., $x(t)$ decays exponentially as $|t|\to+\infty$, then the ROC is the strip between $-b$ and b and $X(s)$ exists. But if $b<0$, i.e., $x(t)$ grows exponentially as $|t|\to+\infty$, then the ROC is an empty set and $X(s)$ does not exist.

E2. Given the following Laplace transform, find the corresponding signal:

$$X(s)=\frac{1}{(s+1)(s+2)}=\frac{1}{s+1}-\frac{1}{s+2} \qquad (7.1.765)$$

Given the two poles $s_{p_1}=-1$ and s_{p_2} of the expression, there are three associated ROCs:

- The half plane to the right of the rightmost pole $s_{p_2}=-1$, with the corresponding right sided time function:

  $$x(t)=e^{-t}u(t)-e^{-2t}u(t) \qquad (7.1.766)$$

- The half plane to the left of the leftmost pole $s_{p_1}=-2$, with the corresponding left sided time function:

  $$x(t)=-e^{-t}u(-t)+e^{-2t}u(-t) \qquad (7.1.767)$$

- The vertical strip between the two poles $-1<\Re[s]<-2$, with the corresponding two sided time function:

  $$x(t)=-e^{-t}u(-t)-e^{-2t}u(t) \qquad (7.1.768)$$

In particular, note that only the first ROC includes the $\mathrm{i}\omega$-axis and the corresponding time function has a Fourier transform. Fourier transform of the other two functions do not exist.

7.1.5.2.5 Properties of Laplace Transform

The Laplace transform has a set of properties in parallel with that of the Fourier transform. The difference is that we need to pay special attention to the ROCs. In the following, we always assume:

$$\mathcal{L}[x(t)]=X(s) \qquad \text{ROC}=R_x \tag{7.1.769}$$

and:

$$\mathcal{L}[y(t)]=Y(s) \qquad \text{ROC}=R_y \tag{7.1.770}$$

P1. Linearity:

$$\mathcal{L}[ax(t)+by(t)]=aX(s)+bY(s) \quad \text{ROC}\supseteq(R_x\cap R_y) \tag{7.1.771}$$

While it is obvious that the ROC of the linear combination of $x(t)$ and $y(t)$ should be the intersection of the their individual ROCs $R_x\cap R_y$ in which both $X(s)$ and $Y(s)$ exist, we note that in some cases when zero-pole cancellation occurs, the ROC of the linear combination could be larger than $R_x\cap R_y$, as shown in the example below.

✍**Example:**

Assume:

$$X(s)=\mathcal{L}[x(t)]=\frac{1}{s+1} \qquad \Re[s]>-1 \tag{7.1.772}$$

and:

$$Y(s)=\mathcal{L}[y(t)]=\frac{1}{(s+1)(s+2)} \qquad \Re[s]>-1 \tag{7.1.773}$$

then:

$$\mathcal{L}[x(t)-y(t)]=\frac{1}{s+1}-\frac{1}{(s+1)(s+2)}=\frac{s+1}{(s+1)(s+2)}=\frac{1}{s+2} \qquad \Re[s]>-2 \tag{7.1.774}$$

P2. Time Shifting:

$$\mathcal{L}[x(t-t_0)]=e^{-t_0 s}X(s) \qquad \text{ROC}=R_x \tag{7.1.775}$$

P3. Shifting in s-Domain:

$$\mathcal{L}[e^{-s_0 t}x(t)]=X(s+s_0) \qquad \text{ROC}=R_x+\Re[s_0] \tag{7.1.776}$$

Note that the ROC is shifted by s_0, i.e., it is shifted vertically by $Im[s_0]$ (with no effect to ROC) and horizontally by $\Re[s_0]$. If R_x is $\Re[s]>0$, the new ROC is $\Re[s+s_0]>0$, i.e., $\Re[s]>-\Re[s_0]$.

P4. Time Scaling:

$$\mathcal{L}[x(at)] = \frac{1}{|a|}X\left(\frac{s}{a}\right) \qquad \text{ROC} = \frac{R_x}{a} \tag{7.1.777}$$

Note that the ROC is horizontally scaled by $1/a$, which could be either positive ($a > 0$) or negative ($a < 0$) in which case both the signal $x(t)$ and the ROC of its Laplace transform are horizontally flipped.

P5. Conjugation:

$$\mathcal{L}[x^*(t)] = X^*(s^*) \qquad \text{ROC} = R_x \tag{7.1.778}$$

Proof 7.3.24.

$$X^*(s^*) = \left[\int\limits_{-\infty}^{+\infty} x(t)e^{-s^*t}\right]^* \mathrm{d}t = \int\limits_{-\infty}^{+\infty} x^*(t)e^{-st}\mathrm{d}t = \mathcal{L}[x^*(t)] \tag{7.1.779}$$

■ Q.E.D.

P6. Convolution:

$$\mathcal{L}[x(t) * y(t)] = X(s)Y(s) \qquad \text{ROC} \supseteq (R_x \cap R_y) \tag{7.1.780}$$

Note that the ROC of the convolution could be larger than the intersection of R_x and R_y, due to the possible pole-zero cancellation caused by the convolution, similar to the linearity property.

✍**Example:**

Assume:

$$X(s) = \mathcal{L}[x(t)] = \frac{s+1}{s+2} \;\; \Re[s] > -2 \;\; \text{and} \quad Y(s) = \mathcal{L}[y(t)] = \frac{s+2}{s+1} \;\; \Re[s] > -1 \tag{7.1.781}$$

then:

$$\mathcal{L}[x(t) * y(t)] = X(s)Y(s) = 1 \;\; \text{ROC} = \text{the entire s-plane} \tag{7.1.782}$$

P7. Differentiation in Time Domain:

$$\mathcal{L}\left[\frac{\mathrm{d}}{\mathrm{d}t}x(t)\right] = sX(s) \quad \text{ROC} \supseteq R_x \tag{7.1.783}$$

This can be proven by differentiating the inverse Laplace transform:

$$\frac{\mathrm{d}}{\mathrm{d}t}x(t) = \frac{1}{\mathrm{i}2\pi}\int\limits_{\sigma-\mathrm{i}\infty}^{\sigma+\mathrm{i}\infty} X(s)\frac{\mathrm{d}}{\mathrm{d}t}e^{st}\mathrm{d}s = \frac{1}{\mathrm{i}2\pi}\int\limits_{\sigma-\mathrm{i}\infty}^{\sigma+\mathrm{i}\infty} sX(s)e^{st}\mathrm{d}s \tag{7.1.784}$$

Again, multiplying $X(s)$ by s may cause pole-zero cancellation and therefore the resulting ROC may be larger than R_x. For example, when $x(t)=u(t)$ and $X(s)=1/s$ with $\Re[s]>0$ as the ROC, $\mathrm{d}x(t)/\mathrm{d}t=\delta(t)$ and with $sX(s)=1$ whose ROC is the entire s-plane. In general, we have:

$$\mathcal{L}\left[\frac{\mathrm{d}^n}{\mathrm{d}t^n}x(t)\right]=s^nX(s) \tag{7.1.785}$$

✍**Example:**

The ROC of $\mathcal{L}[\delta(t)]=1$ is the entire s-plane, and we have:

$$\mathcal{L}\left[\frac{d}{\mathrm{d}t}\delta(t)\right]=s \qquad \text{ROC}=\text{entire s-plane} \tag{7.1.786}$$

and more generally:

$$\mathcal{L}\left[\frac{d^n}{\mathrm{d}t^n}\delta(t)\right]=s^n \qquad \text{ROC}=\text{entire s-plane} \tag{7.1.787}$$

P8. Differentiation in s-Domain:

$$\mathcal{L}[tx(t)]=-\frac{\mathrm{d}}{\mathrm{d}s}X(s) \qquad \text{ROC}=R_x \tag{7.1.788}$$

This can be proven by differentiating the Laplace transform:

$$\frac{\mathrm{d}}{\mathrm{d}s}X(s)=\int\limits_{-\infty}^{+\infty}x(t)\frac{\mathrm{d}}{\mathrm{d}s}e^{-st}\mathrm{d}t=\int\limits_{-\infty}^{+\infty}(-t)x(t)e^{-st}\mathrm{d}t \tag{7.1.789}$$

Repeat this process we get:

$$\mathcal{L}[t^nx(t)]=(-1)^n\frac{\mathrm{d}^n}{\mathrm{d}s^n}X(s) \qquad \text{ROC}=R_x \tag{7.1.790}$$

P9. Integration in Time Domain:

$$\mathcal{L}\left[\int\limits_{-\infty}^{t}x(\tau)\mathrm{d}\tau\right]=\frac{X(s)}{s} \qquad \text{ROC}\supseteq(R_x\cap\{\Re[s]>0\}) \tag{7.1.791}$$

This can be proven by realizing that:

$$x(t)*u(t)=\int\limits_{-\infty}^{+\infty}x(\tau)u(t-\tau)\mathrm{d}\tau=\int\limits_{-\infty}^{t}x(\tau)\mathrm{d}\tau \tag{7.1.792}$$

and therefore by convolution property we have:

$$\mathcal{L}[x(t)*u(t)]=X(s)\frac{1}{s} \tag{7.1.793}$$

Also note that as the ROC of $\mathcal{L}[u(t)]=1/s$ is the right half plane $\Re[s]>0$, the ROC of $X(s)/s$ is the intersection of the two individual ROCs $R_x\cap\{\Re[s]>0\}$, except if pole-zero cancellation occurs (when $x(t)=\mathrm{d}\delta(t)/\mathrm{d}t$ with $X(s)=s$) in which case the ROC is the entire s-plane.

Property name	**Time domain function $f(t)$**	**Laplace Transform $F(s)$**
Linearity	$af(t)+bg(t)$	$aF(s)+bG(s)$
Scale change	$f(at)$	$\dfrac{1}{a}F\left(\dfrac{s}{a}\right)$
Shift	e^{-at}	$F(s+a)$
Delay	$f(t-a)$	$e^{-as}F(s)$
Derivation	$\dfrac{\mathrm{d}f(t)}{\mathrm{d}t}$	$sF(s)-f(0)$
n^{th} Derivation	$\dfrac{\mathrm{d}^nf(t)}{\mathrm{d}t^n}$	$s^nf(s)-s^{n-1}f(0)-s^{n-2}f^1(0)-\ldots-f^{n-1}(0)$

Periodic function	$f(t)=f(t+T)$	$\dfrac{1}{1-e^{-sT}}\displaystyle\int\limits_0^T e^{-sx}f(x)\mathrm{d}x$

Table 7.9: **Summary of most common Laplace transform properties**

7.1.5.2.6 Usual Laplace transforms

As we always do in this textbook, let us see some common usual Laplace Transforms that are useful in some physics and finance well known problems (and also used as example in the MATLAB™ companion book):

1. $\delta(t)$, $\delta(t-\tau)$

$$\mathcal{L}[\delta(t)]=\int\limits_{-\infty}^{+\infty}\delta(t)e^{-st}\mathrm{d}t=e^0=1,\forall s \tag{7.1.794}$$

   Moreover, due to time shifting property, we have:

$$\mathcal{L}[\delta(t-\tau)]=e^{-s\tau},\forall s \tag{7.1.795}$$

2. $u(t)$ (Heaviside function), $t\,u(t)$, $t^n\,u(t)$

   Due to the property of time domain integration, we have:

$$\mathcal{L}[u(t)]=\mathcal{L}\left[\int\limits_{-\infty}^{t}\delta(\tau)d\tau\right]=\frac{1}{s},\quad \Re[s]>0 \tag{7.1.796}$$

   Let us have another more explicit approach as the previous one may be a bit hard.... The function $u(t)$ (for recall it is the Heaviside function defined as $H(t)=0,\forall t<0$) for the usage of the unilateral Laplace transform as it non-null only for $t\geq 0$. Then we have:

$$\mathcal{L}(H(t))(s)=\int\limits_0^{+\infty} H(t)e^{-st}\mathrm{d}t=\int e^{-st}\mathrm{d}t=\left.\frac{e^{-st}}{-s}\right|_0^{+\infty} \tag{7.1.797}$$

This integral converge only if $\sigma\geq 0$. Hence:

$$\mathcal{L}(H(t))(s)=\left.\frac{e^{-st}}{-s}\right|_0^{+\infty}=\frac{\overbrace{e^{-\sigma\cdot+\infty}}^{}_{\to 0}\overbrace{e^{-\mathrm{i}\omega\cdot+\infty}}^{}_{\to 0}}{-(\sigma+\mathrm{i}\omega)}-\frac{e^{\sigma\cdot 0}e^{-\mathrm{i}\omega\cdot 0}}{-(\sigma+\mathrm{i}\omega)}=0-\frac{1}{-s}=\frac{1}{s} \tag{7.1.798}$$

Applying the s-domain differentiation property to the above, we have:

$$\mathcal{L}[tu(t)]=-\frac{\mathrm{d}}{\mathrm{d}s}\left[\frac{1}{s}\right]=\frac{1}{s^2},\quad \Re[s]>0 \tag{7.1.799}$$

Or more explicitly (it sometimes good to see different ways...!) using integration by part:

$$\mathcal{L}(t)(s)=\int\limits_0^{+\infty} te^{-st}\mathrm{d}t=t\left.\frac{e^{-st}}{-s}\right|_0^{+\infty}-\int\limits_0^{+\infty}\frac{e^{-st}}{-s}\mathrm{d}t=t\left.\frac{e^{-st}}{-s}\right|_0^{+\infty}-\frac{1}{s}\left.\frac{e^{-st}}{-s}\right|_0^{+\infty} \tag{7.1.800}$$

By the first term we also see that we must have $\sigma>0$. Which gives us:

$$\mathcal{L}(t)(s)=t\left.\frac{e^{-st}}{-s}\right|_0^{+\infty}-\frac{1}{s}\left.\frac{e^{-st}}{-s}\right|_0^{+\infty}=[0-0]-\left[0-\frac{1}{s^2}\right]=\frac{1}{s^2} \tag{7.1.801}$$

And in general (useful especially in Mechanical Engineering even if so far we were able to avoid its usage in this textbook):

$$\mathcal{L}[t^n u(t)]=\frac{n!}{s^{n+1}},\quad \Re[s]>0 \tag{7.1.802}$$

Indeed, using integration by parts:

$$\mathcal{L}(t^n)s=\int\limits_0^{+\infty} t^n e^{-st}\mathrm{d}t=t^n\left.\frac{e^{-st}}{-s}\right|_0^{+\infty}-n\int\limits_0^{+\infty} t^{n-1}\frac{e^{-st}}{-s}\mathrm{d}t \tag{7.1.803}$$

From the first term we also see that we must have $\sigma>0$. Hence it remains:

$$\begin{aligned}\mathcal{L}(t^n)(s)=-n\int\limits_0^{+\infty} t^{n-1}\frac{e^{-st}}{-s}\mathrm{d}t=\frac{n}{s}\int\limits_0^{+\infty} t^{n-1}e^{-st}\mathrm{d}t=\frac{n}{s}\mathcal{L}(t^{n-1})(s)=\frac{n}{s}\frac{n-1}{s}\mathcal{L}(t^{n-2})(s)\\ =\ldots=\frac{n!}{s^n}\mathcal{L}(1)(s)=\frac{n!}{s^{n+1}}\end{aligned} \tag{7.1.804}$$

It then comes under the condition $\sigma>0$:

$$\begin{aligned}\mathcal{L}(t^0)(s)&=\mathcal{L}(1)(s)=\frac{0!}{s}=\frac{1}{s}\\ \mathcal{L}(t^1)(s)&=\mathcal{L}(t)(s)=\frac{1!}{s^2}=\frac{1}{s^2}\\ \mathcal{L}(t^2)(s)&=\mathcal{L}(t^2)(s)=\frac{2!}{s^3}=\frac{2}{s^3}\\ &\ldots\end{aligned} \tag{7.1.805}$$

3. $e^{-at}u(t)$, $te^{-at}u(t)$

Applying the s-domain shifting property to:

$$\mathcal{L}[u(t)]=\frac{1}{s},\quad \Re[s]>0 \tag{7.1.806}$$

we have:

$$\mathcal{L}[e^{-at}u(t)]=\frac{1}{s+a},\quad \Re[s]>-a \tag{7.1.807}$$

If you don't like using the shift property for that proof, here is a more explicit and long way to get the same result (we change the notation a bit to avoid any confusion):

$$\begin{aligned}\mathcal{L}(e^{xt}H(t))(x)&=\int\limits_{-\infty}^{+\infty} e^{xt}H(t)e^{-st}\mathrm{d}t=\int\limits_{0}^{+\infty} e^{xt}e^{-st}\mathrm{d}t=\int\limits_{0}^{+\infty} e^{(a+\mathrm{i}b)t}e^{-(\sigma+\mathrm{i}\omega)t}\mathrm{d}t\\&=\int\limits_{0}^{+\infty} e^{-((\sigma-a)+\mathrm{i}(\omega-b))t}\mathrm{d}t=\left.\frac{e^{-((\sigma-a)+\mathrm{i}(\omega-b))t}}{-((\sigma-a)+\mathrm{i}(\omega-b))}\right|_0^{+\infty}=\left.\frac{e^{-((\sigma-a)+\mathrm{i}(\omega-b))t}}{x-s}\right|_0^{+\infty}\end{aligned} \tag{7.1.808}$$

We see that the integral will converge if and only if:

$$\sigma>a\qquad \omega>b \tag{7.1.809}$$

Therefore:

$$\mathcal{L}(e^{xt}H(t))(x)=\left.\frac{e^{-((\sigma-a)+\mathrm{i}(\omega-b))t}}{x-s}\right|_0^{+\infty}=0-\frac{1}{x-s}=\frac{1}{s-x} \tag{7.1.810}$$

Applying the same property to:

$$\mathcal{L}[t^n u(t)]=\frac{n!}{s^{n+1}},\quad \Re[s]>0 \tag{7.1.811}$$

we have:

$$\mathcal{L}[t^n e^{-at}u(t)]=\frac{n!}{(s+a)^{n+1}},\quad \Re[s]>-a \tag{7.1.812}$$

4. $e^{-\mathrm{i}\omega_0 t}u(t)$, $\sin(\omega_0 t)u(t)$, $\cos(\omega_0 t)u(t)$

We could make it by integration by parts but it's quite long. The trick is letting $a=\pm\mathrm{i}\omega_0$ in:

$$\mathcal{L}[e^{-at}u(t)]=\frac{1}{s+a},\quad \Re[s]>-\Re[a] \tag{7.1.813}$$

we get:

$$\mathcal{L}[e^{-\mathrm{i}\omega_0 t}u(t)]=\frac{1}{s+\mathrm{i}\omega_0}\ \text{ and }\ \mathcal{L}[e^{\mathrm{i}\omega_0 t}u(t)]=\frac{1}{s-\mathrm{i}\omega_0}\quad \Re[s]>0 \tag{7.1.814}$$

and therefore:

$$\mathcal{L}[\cos(\omega_0 t)u(t)]=\frac{1}{2}\mathcal{L}\left[e^{\mathrm{i}\omega_0 t}+e^{-\mathrm{i}\omega_0 t}\right]=\frac{1}{2}\left[\frac{1}{s-\mathrm{i}\omega_0}+\frac{1}{s+\mathrm{i}\omega_0}\right]=\frac{s}{s^2+\omega_0^2} \tag{7.1.815}$$

and:

$$\mathcal{L}[\sin(\omega_0 t)u(t)]=\frac{1}{2\mathrm{i}}\mathcal{L}\left[e^{\mathrm{i}\omega_0 t}-e^{-\mathrm{i}\omega_0 t}\right]=\frac{1}{2\mathrm{i}}\left[\frac{1}{s-\mathrm{i}\omega_0}-\frac{1}{s+\mathrm{i}\omega_0}\right]=\frac{\omega_0}{s^2+\omega_0^2} \tag{7.1.816}$$

5. $t\ \cos(\omega_0 t)u(t)$, $t\ \sin(\omega_0 t)u(t)$

   Letting $a = \pm \mathrm{i}\omega_0$ in:

$$\mathcal{L}[te^{-at}u(t)] = \frac{1}{(s+a)^2}, \quad \Re[s] > -a \tag{7.1.817}$$

   we get:

$$\mathcal{L}[te^{-\mathrm{i}\omega_0 t}u(t)] = \frac{1}{(s+\mathrm{i}\omega_0)^2} \quad \text{and} \quad \mathcal{L}[te^{\mathrm{i}\omega_0 t}u(t)] = \frac{1}{(s-\mathrm{i}\omega_0)^2}, \quad \Re[s] > -a \tag{7.1.818}$$

   Furthermore we have:

$$\mathcal{L}[t\ \cos(\omega_0 t)u(t)] = \frac{1}{2}\mathcal{L}[t\,(e^{\mathrm{i}\omega_0 t} + e^{-\mathrm{i}\omega_0 t})] = \frac{1}{2}\left[\frac{1}{(s-\mathrm{i}\omega_0)^2} + \frac{1}{(s+\mathrm{i}\omega_0)^2}\right] = \frac{s^2-\omega_0^2}{(s^2+\omega_0^2)^2} \tag{7.1.819}$$

   and:

$$\mathcal{L}[t\ \sin(\omega_0 t)u(t)] = \frac{1}{2\mathrm{i}}\mathcal{L}\left[t\,(e^{\mathrm{i}\omega_0 t} - e^{-\mathrm{i}\omega_0 t})\right] = \frac{1}{2\mathrm{i}}\left[\frac{1}{(s-\mathrm{i}\omega_0)^2} - \frac{1}{(s+\mathrm{i}\omega_0)^2}\right] = \frac{2s\omega_0}{(s^2+\omega_0^2)^2} \tag{7.1.820}$$

6. $e^{-at}\cos(\omega_0 t)u(t)$, $e^{-at}\sin(\omega_0 t)u(t)$

   Applying s-domain shifting property to:

$$\mathcal{L}[\cos(\omega_0 t)u(t)] = \frac{s}{s^2+\omega_0^2} \tag{7.1.821}$$

   and:

$$\mathcal{L}[\sin(\omega_0 t)u(t)] = \frac{\omega_0}{s^2+\omega_0^2} \tag{7.1.822}$$

   we get, respectively:

$$\mathcal{L}[e^{-at}\cos(\omega_0 t)u(t)] = \frac{s+a}{(s+a)^2+\omega_0^2} \tag{7.1.823}$$

   and:

$$\mathcal{L}[e^{-at}\sin(\omega_0 t)u(t)] = \frac{\omega_0}{(s+a)^2+\omega_0^2} \tag{7.1.824}$$

7. Let us see an important transform pair that we will find invaluable when we get to transients in transmission lines and in advanced quantitative finance[7]. Specifically, if we define the "Gauss error function":

$$\text{erf}(t) = \frac{2}{\sqrt{\pi}}\int_0^t e^{-u^2}\mathrm{d}u \tag{7.1.825}$$

   then we will derive here the pair of unilateral Laplace transform:

$$1 - \text{erf}\left(\frac{a}{2\sqrt{t}}\right) \leftrightarrow \frac{1}{s}e^{-a\sqrt{s}} \tag{7.1.826}$$

---

[7] Notice that the entire development that will follow is inspired from the excellent book: *Transients for Electrical Engineers* **??**.

Proof 7.3.25. We will start by computing the Laplace transform of:

$$x(t)=\frac{e^{-a^2/4t}}{\sqrt{\pi t^3}} \tag{7.1.827}$$

How do we know we have to start from this? Because this function appears in the book *Analytical Theory of Heat* (11822 according to holocene calendar) of Joseph Fourier where he already did the job before us but in a different painful way[8]!

In any case what we have is:

$$X(s)=\mathcal{UL}(x(t))=\int\limits_0^{+\infty}x(t)e^{-st}\mathrm{d}t=\int\limits_0^{+\infty}\frac{e^{-a^2/4t}}{\sqrt{\pi t^3}}\mathrm{d}t \tag{7.1.828}$$

Next, let us make the change of variable:

$$\tau^2=\frac{a^2}{4t} \tag{7.1.829}$$

and so:

$$\tau=\frac{a}{2t^{1/2}} \tag{7.1.830}$$

Therefore:

$$\mathrm{d}t=-\sqrt{t^3}\frac{4}{a}\mathrm{d}\tau \tag{7.1.831}$$

With this our unilateral Laplace transforms becomes:

$$\begin{aligned}X(s)&=\int\limits_{+\infty}^{0}\frac{e^{-\tau^2}}{\sqrt{\pi t^3}}e^{-s\frac{a^2}{4\tau^2}}\left(-\sqrt{t^3}\frac{4}{a}\mathrm{d}\tau\right)=-\frac{4}{a\sqrt{\pi}}\int\limits_{+\infty}^{0}e^{-\left[\tau^2+s\frac{a^2}{4\tau^2}\right]}\mathrm{d}\tau\\&=\frac{4}{a\sqrt{\pi}}\int\limits_0^{+\infty}e^{-\left[\tau^2+s\dfrac{a^2}{4\tau^2}+a\sqrt{s}-a\sqrt{s}\right]}\mathrm{d}\tau=\frac{4}{a\sqrt{\pi}}e^{-a\sqrt{s}}\int\limits_0^{+\infty}e^{-\left[\tau^2-a\sqrt{s}+\left(s\frac{a\sqrt{s}}{2\tau}\right)^2\right]}\mathrm{d}\tau\\&=\frac{4}{a\sqrt{\pi}}e^{-a\sqrt{s}}\int\limits_0^{+\infty}e^{-\left(\tau-\frac{a\sqrt{s}}{2\tau}\right)^2}\mathrm{d}\tau\end{aligned} \tag{7.1.832}$$

Or:

$$X(s)=\frac{4}{a\sqrt{\pi}}e^{-a\sqrt{s}}\int\limits_0^{+\infty}e^{-\left(\tau-\frac{b}{\tau}\right)^2}\mathrm{d}\tau \tag{7.1.833}$$

where:

$$b=\frac{a\sqrt{s}}{2} \tag{7.1.834}$$

---

[8] You can find it in the English translation of year 11878 according to holocene calendar (see [188]) at the page 384 for $\mathbb{R}^3$.

Now, concentrate on the integral, alone. Multiplying out the exponent of the integrand, we have:

$$\int\limits_0^{+\infty} e^{-\left(\tau^2-2b+\frac{b^2}{\tau^2}\right)^2}\mathrm{d}\tau=e^{2b}\int\limits_0^{+\infty} e^{-\left(\tau^2+\frac{b^2}{\tau^2}\right)^2}\mathrm{d}\tau=e^{2b}I(b) \tag{7.1.835}$$

where:

$$I(b)=\int\limits_0^{+\infty} e^{-\left(\tau^2+\frac{b^2}{\tau^2}\right)^2}\mathrm{d}\tau \tag{7.1.836}$$

The integral $I(b)$, despite its perhaps complicated appearance, can be evaluated as follows.

Differentiating with respect to b we get:

$$\frac{\mathrm{d}I}{\mathrm{d}b}=\int\limits_0^{+\infty}\left(-\frac{2b}{\tau^2}\right)e^{-\left(\tau^2+\frac{b^2}{\tau^2}\right)^2}\mathrm{d}\tau \tag{7.1.837}$$

Now, make the change of variable:

$$u=\frac{b}{\tau}\Leftrightarrow\tau=\frac{b}{u} \tag{7.1.838}$$

which leads to:

$$\mathrm{d}\tau=-\frac{b}{u^2}\mathrm{d}u \tag{7.1.839}$$

and so:

$$\frac{\mathrm{d}I}{\mathrm{d}b}=\int\limits_{+\infty}^{0}\left(-\frac{2u^2}{b}\right)e^{-\left(\frac{b^2}{u^2}+u^2\right)}\left(-\frac{b}{u^2}\mathrm{d}u\right)=-2\int\limits_0^{+\infty}e^{-\left(\frac{b^2}{u^2}+u^2\right)}\mathrm{d}u=-2I(b) \tag{7.1.840}$$

Thus:

$$\frac{\mathrm{d}I}{I}=-2\mathrm{d}b \tag{7.1.841}$$

which the primitive gives:

$$I(b)=c^{te}e^{-2b} \tag{7.1.842}$$

where c^{te} is some constant. We can determine it easily with (see section Statistics page 695):

$$I(0)=c^{te}=\int\limits_0^{+\infty}e^{-\tau^2}\mathrm{d}\tau=\frac{\sqrt{\pi}}{2} \tag{7.1.843}$$

the reader may have indeed recognized the Gauss integral here.

So:

$$I(b)=\frac{\sqrt{\pi}}{2}e^{-2b} \tag{7.1.844}$$

And putting into:

$$\int\limits_0^{+\infty} e^{-\left(\tau-\frac{b}{\tau}\right)^2}\mathrm{d}\tau=\int\limits_0^{+\infty} e^{-\left(\tau^2-2b+\frac{b^2}{\tau^2}\right)^2}\mathrm{d}\tau=e^{2b}\int\limits_0^{+\infty} e^{-\left(\tau^2+\frac{b^2}{\tau^2}\right)^2}\mathrm{d}\tau=e^{2b}I(b) \tag{7.1.845}$$

We get:

$$\int\limits_0^{+\infty} e^{-\left(\tau-\frac{b}{\tau}\right)^2}\mathrm{d}\tau=\frac{\sqrt{\pi}}{2} \tag{7.1.846}$$

And putting also back into:

$$X(s)=\frac{4}{a\sqrt{\pi}}e^{-a\sqrt{s}}\int\limits_0^{+\infty} e^{-\left(\tau-\frac{b}{\tau}\right)^2}\mathrm{d}\tau=\frac{4}{a\sqrt{\pi}}e^{-a\sqrt{s}}\frac{\sqrt{\pi}}{2}=\left(\frac{2}{a}e^{-a\sqrt{s}}\right) \tag{7.1.847}$$

Which gives us indeed the pair (that will be useful to us for the study of the Telegrapher equation):

$$\frac{e^{-a^2/4t}}{\sqrt{\pi t^3}}\leftrightarrow\frac{2}{a}e^{-a\sqrt{s}} \tag{7.1.848}$$

Which is equivalent:

$$\frac{ae^{-a^2/4t}}{2\sqrt{\pi t^3}}\leftrightarrow e^{-a\sqrt{s}} \tag{7.1.849}$$

Finally, recall that we have proved during our studies of main Laplace transform properties the (see section Analysis page 2345) following pair (integration in time domain):

$$\int\limits_0^{+\infty} x(t)\mathrm{d}t\leftrightarrow\frac{X(s)}{s} \tag{7.1.850}$$

Therefore:

$$\int\limits_0^{+\infty}\frac{ae^{-a^2/4t}}{2\sqrt{\pi t^3}}\mathrm{d}t\leftrightarrow\frac{e^{-a\sqrt{s}}}{s} \tag{7.1.851}$$

In the integral above let us make the following change of variable:

$$u=\frac{a}{2\sqrt{t}} \tag{7.1.852}$$

Therefore:

$$\mathrm{d}t=-\frac{4\sqrt{t^3}}{a}\mathrm{d}u \tag{7.1.853}$$

and so:

$$\frac{a}{2\sqrt{\pi}}\int\limits_{+\infty}^{\frac{a}{2\sqrt{t}}}\frac{e^{-u^2}}{\sqrt{x^3}}\left(-\frac{4\sqrt{x^3}}{a}\mathrm{d}u\right)=\frac{2}{\sqrt{\pi}}\int\limits_{\frac{a}{2\sqrt{t}}}^{+\infty}e^{-u^2}\mathrm{d}u=\frac{2}{\sqrt{\pi}}\left[\int\limits_0^{+\infty}e^{-u^2}\mathrm{d}u-\int\limits_0^{\frac{a}{2\sqrt{t}}}e^{-u^2}\mathrm{d}u\right] \tag{7.1.854}$$

In the first integral in the square brackets we recognize the half of the Gauss integral. Therefore:

$$\frac{2}{\sqrt{\pi}}\left[\int\limits_0^{+\infty}e^{-u^2}\mathrm{d}u-\int\limits_0^{\frac{a}{2\sqrt{t}}}e^{-u^2}\mathrm{d}u\right]=\frac{2}{\sqrt{\pi}}\left[\frac{\sqrt{\pi}}{2}-\int\limits_0^{\frac{a}{2\sqrt{t}}}e^{-u^2}\mathrm{d}u\right] \tag{7.1.855}$$

In the second one we recognize the Gauss error function (see page 3697), therefore:

$$\frac{2}{\sqrt{\pi}}\left[\frac{\sqrt{\pi}}{2}-\int\limits_0^{\frac{a}{2\sqrt{t}}}e^{-u^2}\mathrm{d}u\right]=\frac{2}{\sqrt{\pi}}\left[\frac{\sqrt{\pi}}{2}-\frac{\sqrt{\pi}}{2}\mathrm{erf}\left(\frac{a}{2\sqrt{t}}\right)\right]=1-\mathrm{erf}\left(\frac{a}{2\sqrt{t}}\right) \tag{7.1.856}$$

Therefore our pair:

$$\int\limits_0^{+\infty}\frac{ae^{-a^2/4t}}{2\sqrt{\pi t^3}}\mathrm{d}t\leftrightarrow\frac{e^{-a\sqrt{s}}}{s} \tag{7.1.857}$$

can be rewritten:

$$1-\mathrm{erf}\left(\frac{a}{2\sqrt{t}}\right)\leftrightarrow\frac{e^{-a\sqrt{s}}}{s} \tag{7.1.858}$$

and so, at last, we have the claimed pair of the beginning!

■ Q.E.D.

To summarize:

Table 7.10: **Most common Laplace transform**

7.1.5.2.7 Solving differential systems

Let us see now a well known simple academic companion example of the application of the Laplace transform to deal with differential equations.

$$\text{origin space}\left\{\begin{tikzcd} \text{ODE in } t \arrow[r, "\mathcal{L}"] \arrow[d, dashed] & \text{eqn. in } s \arrow[d] \\ y(t) & Y(s) \arrow[l, "\mathcal{L}^{-1}"'] \end{tikzcd}\right\}\text{transform space}$$

Let us consider that a voltage $x(t)$ is applied as the input to a resistor R, a capacitor C and an inductor L connected in series (the case without the use of the Laplace transform is introduced in details in the section of Electrical Engineering page 8475). The output $y(t)$ is the voltage across one of the three elements. The system can be described by a differential equation in time domain:

$$x(t)=v_L(t)+v_R(t)+v_C(t)=L\frac{\mathrm{d}}{\mathrm{d}t}\,i(t)+R\,i(t)+\frac{1}{C}\int_{-\infty}^{t}i(\tau)\mathrm{d}\tau \tag{7.1.859}$$

or by an algebraic equation in s-domain:

$$X(s)=V_L(s)+V_R(s)+V_C(s)=\left[sL+R+\frac{1}{sC}\right]I(s) \tag{7.1.860}$$

and the overall impedance of the circuit is defined as the ratio between voltage $V(s)$ and the current $I(s)$:

$$Z(s)\overset{\triangle}{=}\frac{V(s)}{I(s)}=sL+R+\frac{1}{sC} \tag{7.1.861}$$

which is composed of the individual impedance of the three elements:

$$Z_L(s)=sL,\quad Z_R(s)=R,\quad Z_C(s)=\frac{1}{sC} \tag{7.1.862}$$

	resistor R	capacitor C	inductor L
time domain	$i=\frac{v}{R}$	$i=\frac{1}{C}\frac{\mathrm{d}v}{\mathrm{d}t}$	$v=\frac{1}{L}\frac{\mathrm{d}i}{\mathrm{d}t}$
s-domain	$V_R=IR$	$V_C=I/Cs$	$V_L=IsL$
impedance $Z=V/I$	R	$1/sC$	sL

If the output is the voltage across one of the three elements (V_L, V_R, or V_C), the transfer function $H(s)$ can be easily obtained by treating the series circuit as a voltage divider:

- Output is voltage across the capacitor $v_C(t)$

$$H_C(s)=\frac{1/sC}{Ls+R+1/sC}=\frac{1/LC}{s^2+(R/L)s+(1/LC)} \tag{7.1.863}$$

- Output is voltage across the resistor $v_R(t)$

$$H_R(s)=\frac{R}{Ls+R+1/sC}=\frac{(R/L)s}{s^2+(R/L)s+(1/LC)} \tag{7.1.864}$$

- Output is voltage across the inductor $v_L(t)$

$$H_L(s)=\frac{sL}{Ls+R+1/sC}=\frac{s^2}{s^2+(R/L)s+(1/LC)} \tag{7.1.865}$$

If we define:

$$\zeta\overset{\triangle}{=}\frac{R}{2}\sqrt{\frac{C}{L}},\quad \omega_n\overset{\triangle}{=}\frac{1}{\sqrt{LC}} \tag{7.1.866}$$

the common denominator of the transfer functions can be written in standard (canonical) form:

$$s^2+(R/L)s+(1/LC)=s^2+2\zeta\omega_n s+\omega_n^2 \tag{7.1.867}$$

with two roots:

$$p_{1,2}=(-\zeta\pm\sqrt{\zeta^2-1})\omega_n \tag{7.1.868}$$

and the transfer functions above can be written in standard forms:

- The first one:

  $$H_C(s)=\frac{\omega_n^2}{s^2+2\zeta\omega_n s+\omega_n^2} \tag{7.1.869}$$

  with two poles p_1,p_2 and no zeros.

- The second one:

  $$H_R(s)=\frac{2\zeta\omega_n s}{s^2+2\zeta\omega_n s+\omega_n^2} \tag{7.1.870}$$

  with two poles p_1,p_2 and one zero at the origin.

- The third one:

  $$H_L(s)=\frac{s^2}{s^2+2\zeta\omega_n s+\omega_n^2} \tag{7.1.871}$$

  with two poles p_1,p_2 and two repeated zeros at the origin.

The three transfer functions behave like low-pass, band-pass and high-pass filter, respectively. Moreover, when the common real part $-\zeta\omega_n$ of the two complex conjugate poles is small (i.e., $0<\zeta<0.5$), there will be a narrow pass-band around $\omega=\omega_n$ for all three transfer functions. The magnitude and phase angle of the corresponding frequency response function $|H(\mathrm{i}\omega)|$ can be qualitatively determined in the s-plane, as to be discussed later.

7.1.5.2.8 Unilateral Laplace Transform

The Laplace transform so far discussed is the "bilateral Laplace transform" as it can be applied to left sided signals as well as right sided ones. Now we will consider the "unilateral Laplace transform" of an arbitrary signal $x(t)$ defined as:

$$\boxed{\mathcal{UL}(x(t))=X(s)\triangleq\int_{-\infty}^{+\infty}x(t)u(t)e^{-st}\mathrm{d}t=\int_{0^-}^{+\infty}x(t)e^{-st}\mathrm{d}t} \tag{7.1.872}$$

where for recall $\mathcal{U}$ and $u(t)$ are another typical notation of the Heaviside function.

This definition always assumes $x(t)=0$ for $t<0$. When the unilateral Laplace transform is applied to find the transfer function $H(s)=\mathcal{UL}[h(t)]$ of a LTI system, it is always assumed to be causal. And the ROC is always right sided in s-plane.

By definition, the unilateral Laplace transform of any signal $x(t)=x(t)u(t)$ is identical to its bilateral Laplace transform. However, when $x(t)\neq x(t)u(t)$, the two Laplace transforms are different.

Unilateral Laplace Transform shares all the properties of bilateral Laplace transform, except some of the properties are expressed in different forms. Here we only consider the differentiation in time domain:

$$\mathcal{UL}\left[\frac{\mathrm{d}}{\mathrm{d}t}x(t)\right]=\mathcal{UL}[x'(t)]=sX(s)-x(0^-) \tag{7.1.873}$$

Proof 7.3.26.

$$\begin{aligned}\mathcal{UL}\left[\frac{\mathrm{d}}{\mathrm{d}t}x(t)\right]&=\int\limits_{0^-}^{+\infty}x'(t)e^{-st}\mathrm{d}t=\int\limits_{0^-}^{+\infty}e^{-st}\mathrm{d}[x(t)]=x(t)e^{-st}|_{0^-}^{+\infty}-\int\limits_{0^-}^{+\infty}x(t)\mathrm{d}(e^{-st})\\&=-x(0)+s\int\limits_{0^-}^{+\infty}x(t)e^{-st}\mathrm{d}t=sX(s)-x(0^-)\end{aligned} \tag{7.1.874}$$

■ Q.E.D.

We can further get Laplace transform of higher order derivatives:

$$\mathcal{UL}[x''(t)]=s\mathcal{UL}[x'(t)]-x'(0^-)=s^2X(s)-sx(0^-)-x'(0^-) \tag{7.1.875}$$

and in general:

$$\mathcal{UL}[x^{(n)}(t)]=s^nX(s)-\sum_{k=0}^{n-1}s^kx^{(n-1-k)}(0^-) \tag{7.1.876}$$

To finish depending on donations

7.1.5.3 $\mathcal{Z}$-Transform

Laplace transforms (whose Fourier transform is for recall a special case) is applicable only for functions say ... "continuous" to make it simple.... But since the advent of computing the vast majority of functions (signals) are samples at a time interval T_s such that the functions are actually discrete.

From then on it becomes useful to define a transformation similar to the Laplace transform but in the discrete case! Thus, the Laplace transform becomes a special case of the $\mathcal{Z}$-transform when the sampling period T_s tends to 0.

The discrete Fourier transform of a discrete signal $x[n]$ is defined for recall as:

$$X(e^{\mathrm{i}\omega})=\mathcal{F}[x[n]]=\sum_{n=-\infty}^{+\infty}x[n]e^{-\mathrm{i}2\pi fn}=\sum_{n=-\infty}^{+\infty}x[n]e^{-\mathrm{i}\omega n} \tag{7.1.877}$$

provided $x[n]$ is absolutely summable:

$$\sum_{n=-\infty}^{+\infty}|x[n]|<+\infty \tag{7.1.878}$$

Obviously some signals may not satisfy this condition and their Fourier transform do not exist. To overcome this difficulty, we can multiply the given $x[n]$ by an exponential function $e^{-\sigma n}$ so that $x[n]$ may be forced to be summable for certain values of the real parameter σ. Now the discrete time Fourier transform becomes:

$$\begin{aligned}\mathcal{F}[x[n]e^{-\sigma n}]&=\sum_{n=-\infty}^{+\infty}\left[x[n]e^{-\sigma n}\right]e^{-\mathrm{i}\omega n}=\sum_{n=-\infty}^{+\infty}x[n]e^{-(\sigma+\mathrm{i}\omega)n}\\&=\sum_{n=-\infty}^{+\infty}x[n]e^{-sn}=\sum_{n=-\infty}^{+\infty}x[n]z^{-n}=X(z)\end{aligned} \tag{7.1.879}$$

The result of this summation is a function of a complex variable defined as:

$$z=e^s=e^{\sigma+\mathrm{i}\omega} \tag{7.1.880}$$

This is the "forward (bilateral) $\mathcal{Z}$-transform" of the discrete signal $x[n]$:

$$\boxed{X(z)=\mathcal{Z}[x[n]]=\sum_{n=-\infty}^{+\infty}x[n]z^{-n}} \tag{7.1.881}$$

There is another way to introduce the $\mathcal{Z}$-transform that result to the same result but with different notation and that is more explicit. As it may help the reader to better understand, let us show that but by limiting ourselves to positive times only (the case of interest in engineering is the unilateral $\mathcal{Z}$-transform!).

So we know that a continuous function $f(t)t$ can be discretized (sampled) in a way to take at each time step nT_s with $n\in\mathbb{N}$ the value of the function of interest, multiplied by a Dirac pulse on this same point such that:

$$f_s(t) \underset{\lim T_s \to 0}{=} \sum_{0}^{+\infty} f(nT_s)\delta(t-nT_s) \qquad (7.1.882)$$

Now let us calculate the Laplace transform of this discretized function at the limit and using the fact that the $f(nT_e)$ are henceforth independent from the time and the linearity property of the Laplace transform:

$$\mathcal{L}(f_s(t))(s) = \int_0^{+\infty} \sum_{n=0}^{+\infty} f(nT_s)\delta(t-nT_s)\mathrm{d}t = \sum_{n=0}^{+\infty} \left[f(nT_s) \int_0^{+\infty} \delta(t-nT_s)\mathrm{d}t \right] \qquad (7.1.883)$$

As we have shown above in our study of the usual Laplace transforms, we have:

$$\int_0^{+\infty} \delta(t-nT_s) = e^{-nsT} \qquad (7.1.884)$$

Then we have:

$$\mathcal{L}(f_s(t))(s) = \sum_{n=0}^{+\infty} f(nT_s)e^{-nst} \qquad (7.1.885)$$

That is usage as we have just seen before to write as following and define as the "unilateral $\mathcal{Z}$-transform" (on which we will come back later below):

$$\mathcal{Z}(f_s(t))(z) = \sum_{n=0}^{+\infty} f_n z^{-n} \qquad (7.1.886)$$

with:

$$f_n = f(nT_s) \qquad z = e^{st} \qquad (7.1.887)$$

That's it for the second approach!

Now, given the $\mathcal{Z}$-transform $X(z)$, the original time signal can be obtained by the inverse $\mathcal{Z}$-transform, which can be derived from the corresponding discrete Fourier transform. As shown above, we have:

$$X(z) = X(e^{\sigma+\mathrm{i}\omega}) = \sum_{n=-\infty}^{+\infty} [x[n]e^{-\sigma n}]e^{-\mathrm{i}\omega n} = \mathcal{F}[x[n]e^{-\sigma n}] \qquad (7.1.888)$$

Now $x[n]e^{-\sigma n}$ can be obtained by the inverse Fourier transform:

$$x[n]e^{-\sigma n} = \mathcal{F}^{-1}[X(e^{\sigma+\mathrm{i}\omega})] = \frac{1}{2\pi}\int_0^{2\pi} X(e^{\sigma+\mathrm{i}\omega})e^{\mathrm{i}\omega n}\mathrm{d}\omega \qquad (7.1.889)$$

Multiplying both sides by $e^{\sigma n}$, we get:

$$x[n] = \frac{1}{2\pi}\int_0^{2\pi} X(e^{\sigma+\mathrm{i}\omega})e^{(\sigma+\mathrm{i}\omega)n}\mathrm{d}\omega = \frac{1}{2\pi}\int_0^{2\pi} X(z)z^n\mathrm{d}\omega \qquad (7.1.890)$$

To represent the inverse transform in terms of z (instead of ω), we note:

$$\mathrm{d}z = \mathrm{d}(e^{\sigma+\mathrm{i}\omega}) = e^{\sigma}\mathrm{i}e^{\mathrm{i}\omega}\mathrm{d}\omega = \mathrm{i}z\,\mathrm{d}\omega \tag{7.1.891}$$

i.e.:

$$\mathrm{d}\omega = \frac{\mathrm{d}z}{\mathrm{i}z} \tag{7.1.892}$$

and the "inverse $\mathcal{Z}$-transform" can be obtained as:

$$\boxed{x[n] = \mathcal{Z}^{-1}[X(z)] = \frac{1}{\mathrm{i}2\pi}\oint X(z)z^{n-1}\mathrm{d}z} \tag{7.1.893}$$

Note that the integral with respect to ω from 0 to 2π becomes an integral with respect to $z = e^{\sigma+\mathrm{i}\omega}$ in the complex z-plane, along a circle with a fixed radius e^{σ} and a varying angle ω from 0 to 2π. Now we have the $\mathcal{Z}$-transform pair:

$$X(z) = \mathcal{Z}[x[n]] = \sum_{n=-\infty}^{+\infty} x[n]z^{-n} \tag{7.1.894}$$

$$x[n] = \mathcal{Z}^{-1}[X(z)] = \frac{1}{2\pi\mathrm{i}}\oint X(z)z^{n-1}\mathrm{d}z \tag{7.1.895}$$

The forward and inverse $\mathcal{Z}$-transform pair can also be represented as:

$$x[n] \overset{\mathcal{Z}}{\longleftrightarrow} X(z) \tag{7.1.896}$$

In particular, if we let $\sigma = 0$, i.e., $z = e^{\mathrm{i}\omega}$, then the $\mathcal{Z}$-transform becomes the discrete-time Fourier transform:

$$X(z)\Big|_{z=e^{\mathrm{i}\omega}} = \sum_{n=-\infty}^{+\infty} x[n]e^{-\mathrm{i}\omega n} = X(e^{\mathrm{i}}\omega) \tag{7.1.897}$$

This is the reason why sometimes the discrete Fourier spectrum is expressed as a function of $e^{\mathrm{i}\omega}$.

Different from the discrete-time Fourier transform which converts a 1-D signal $x[n]$ in time domain to a 1-D complex spectrum $X(e^{\mathrm{i}\omega})$ in frequency domain, the $\mathcal{Z}$-transform $X(s)$ converts the 1-D signal $x[n]$ to a complex function defined over a 2-D complex plane, named the "z-plane", represented in polar form by radius $|z| = |e^{\sigma+\mathrm{i}\omega}| = e^{\sigma}$ and angle $\angle z = \angle(e^{\sigma+\mathrm{i}\omega}) = \omega$.

In particular, when this 2-D function $X(z) = X(e^{\sigma+\mathrm{i}\omega})$ is evaluated along the unit circle $|z| = e^{0} = 1$ corresponding to $\sigma = 0$, it becomes a 1-D periodic function $X(e^{\mathrm{i}\omega})$, the discrete Fourier transform of $x[n]$.

7.1.5.3.1 Transfer function of LTI system

The output $y[n]$ of a discrete LTI (Linear Time-Invariant) system with input $x[n]$ can be found by convolution (see page 2293):

$$y[n]=\mathcal{O}[x[n]]=h[n]*x[n]=\sum_{k=-\infty}^{+\infty} h[k]x[n-k] \tag{7.1.898}$$

where $h[n]$ is the impulse response function of the system. In particular, if the input is a complex exponential:

$$x[n]=z^n=(e^s)^n=e^{sn} \tag{7.1.899}$$

then the output $y[n]$ can be found to be:

$$y[n]=\mathcal{O}[z^n]=\sum_{k=-\infty}^{+\infty} h[k]z^{n-k}=z^n\sum_{k=-\infty}^{+\infty} h[k]z^{-k}=H(z)z^n \tag{7.1.900}$$

This is the eigenequation with the complex exponential $x[n]=z^n=e^{sn}$ being the eigenfunction of any discrete LTI system, corresponding to its eigenvalue defined as:

$$H(z)\triangleq\sum_{k=-\infty}^{+\infty} h[k]z^{-k} \tag{7.1.901}$$

which is the $\mathcal{Z}$-transform of its impulse response $h[n]$, called the "transfer function" of the LTI system. In particular, when $\sigma=0$, i.e., $z=e^s=e^{\mathrm{i}\omega}$, the transfer function $H(z)$ becomes the frequency response function, the Fourier transform of the impulse response:

$$H(e^{\mathrm{i}\omega})\triangleq\sum_{n=-\infty}^{+\infty} h[n]e^{-\mathrm{i}\omega n} \tag{7.1.902}$$

7.1.5.3.2 Conformal mapping between s-plane to z-plane

The s-plane and the z-plane are related by a conformal mapping (i.e. conserves the angles) specified by the analytic complex function:

$$z=e^s=e^{\sigma+\mathrm{i}\omega}=e^{\sigma}e^{\mathrm{i}\omega}=re^{\mathrm{i}\omega} \tag{7.1.903}$$

where :

$$\begin{cases}\Re[s]=\sigma\\ \Im[s]=\mathrm{i}\omega\end{cases}\quad\text{and}\quad\begin{cases}|z|=r=e^{\sigma}\\ \angle z=\omega\end{cases} \tag{7.1.904}$$

Even if, as far as we know, there are no important practical application of this mapping, it is more a mathematical curiosity the may help some students to understand how the s-plane and z-plane are related together.

The mapping is continuous, i.e., neighbouring points in s-plane are mapped to neighbouring points in z-plane and vice versa. Consider the mapping of these specific features:

- The origin $s=0$ of s-plane is mapped to $z=e^0=1$ on the real axis in z-plane.
- Each vertical line $\Re[s]=\sigma_0$ in s-plane is mapped to a circle $|z|=e^{\sigma_0}$ centered about the origin in z-plane. In particular:
  - Leftmost vertical line $\Re[s]=\sigma=-\infty$ is mapped as the origin $|z|=e^{-\infty}=0$
  - Imaginary axis $\Re[s]=0$ is mapped as the unit circle $|z|=e^0=1$
  - Rightmost vertical line $\Re[s]=\sigma=+\infty$ is mapped as a circle of infinite radius $|z|=e^{+\infty}=+\infty$.
- Each horizontal line $\Im[s]=\mathrm{i}\omega_0$ in s-plane is mapped to $\angle z=\omega_0$, a ray from the origin in z-plane of angle ω_0 with respect to the positive horizontal direction.
- A right angle formed by a pair vertical and horizontal lines in s-plane is conserved by the mapping, as the corresponding circle and ray in z-plane also form a right angle (in fact any angle is conserved, an important property of the conformal mapping).

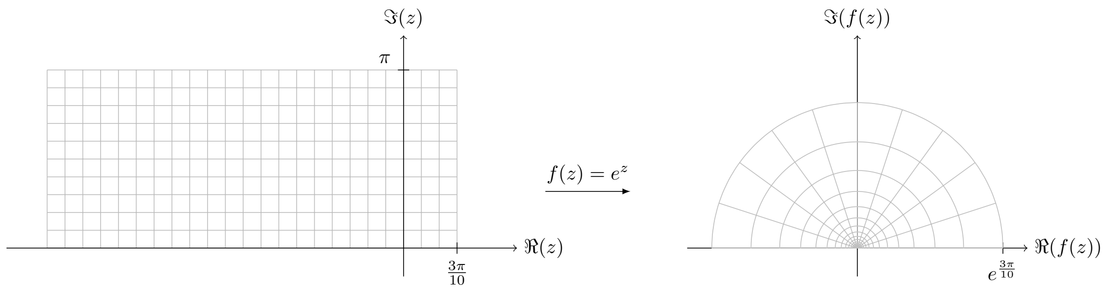

Figure 7.67: Example of a simple complex conformal mapping

The infinite range $-\infty<\omega<+\infty$ for frequency ω along a vertical line $\Re[s]=\sigma_0$ in s-plane is mapped repeatedly to a finite range $0\leq\omega<2\pi$ around a circle $|z|=e^{\sigma_0}$ in z-plane, corresponding to the conversion of a continuous signal $x(t)$ with non-periodic spectrum $X(\mathrm{i}\omega)$ for $-\infty<\omega<+\infty$ to a discrete signal $x[n]$ with periodic spectrum $X(e^{\mathrm{i}\omega})$ for $0\leq\omega<2\pi$.

7.1.5.3.3 Region of Convergence

Whether the $\mathcal{Z}$-transform $X(z)$ of a signal $x[n]$ exists depends on the complex variable $z=e^s$ as well as the signal itself. $X(z)$ exists if and only if the argument z is inside the region of convergence (ROC) in the z-plane, which is composed of all z values for the summation of the $\mathcal{Z}$-transform to converge. The ROC of the $\mathcal{Z}$-transform is determined by $|z|=|e^s|=e^\sigma$ (a circle), the magnitude of variable z, while the ROC for the Laplace transform is determined by $\sigma=\Re[s]$, (a vertical line), the real part of s.

✍**Examples:**

E1. Let us see our first $\mathcal{Z}$-transform with at the same time its corresponding region of convergence. For this purpose, let us first recall the following geometric series (see page 2419):

$$\sum_{n=0}^{+\infty}=\frac{1}{1-x} \tag{7.1.905}$$

for $|x|<1$. The $\mathcal{Z}$-transform of the following right sided signal $x[n]=a^n u[n]$ is:

$$X(z)=\sum_{n=-\infty}^{+\infty} a^n u[n]z^{-n}=\sum_{n=0}^{+\infty}(az^{-1})^n=\frac{1}{1-az^{-1}}=\frac{z}{z-a} \tag{7.1.906}$$

If we put $a=1$, we simply get the $\mathcal{Z}$-transform of the Heaviside function (as a simple geometric series: $1+z^{-1}+z^{-2}+\ldots$)

For this summation to converge, i.e., for $X(z)$ to exist, it is necessary to have $|az^{-1}|<1$, i.e., the ROC is $|z|>|a|$. As a special case when $a=1$, $x[n]=u[n]$ and we have:

$$\mathcal{Z}[u[n]]=\frac{1}{1-z^{-1}},\quad |z|>1 \tag{7.1.907}$$

E2. Let us see now a simple trivial example of an inverse of the following given $\mathcal{Z}$-transform:

$$X(z)=4z^2+2+3z^{-1} \tag{7.1.908}$$

Comparing this with the definition of $\mathcal{Z}$-transform:

$$X(z)=\sum_{n=-\infty}^{+\infty} x[n]z^{-n}=x[-2]z^2+x[-1]z^1+x[0]+x[1]z^{-1}+x[2]z^{-2} \tag{7.1.909}$$

we get:

$$x[n]=4\delta[n+2]+2\delta[n]+3\delta[n-1] \tag{7.1.910}$$

In general, we can use the time shifting property:

$$\mathcal{Z}[\delta[n+n_0]]=z^{n_0} \tag{7.1.911}$$

to inverse transform the $X(z)$ given above to $x[n]$ directly.

E3. Let us determine the obvious inverse transform of:

$$X(z)=\frac{1}{1-az^{-1}} \tag{7.1.912}$$

As we know that:

$$\frac{1}{1-az^{-1}}=1+az^{-1}+a^2z^{-2}+\cdots \tag{7.1.913}$$

which converges if the ROC is $|z|>|a|$, i.e., $|az^{-1}|<1$ then we get:

$$x[n]=a^n u[n] \tag{7.1.914}$$

7.1.5.3.4 Zeros and Poles of $\mathcal{Z}$-Transform

All $\mathcal{Z}$-transforms in the above examples are rational, i.e., they can be written as a ratio of polynomials of variable z in the general form:

$$X(z)=\frac{N(z)}{D(z)}=\frac{\displaystyle\sum_{k=0}^{M} b_k z^k}{\displaystyle\sum_{k=0}^{N} a_k z^k}=\frac{b_M}{a_N}\frac{\displaystyle\prod_{k=1}^{M}(z-z_{z_k})}{\displaystyle\prod_{k=1}^{N}(z-z_{p_k})} \tag{7.1.915}$$

where $N(z)$ is the numerator polynomial of order M with roots $z_{z_k}, (k=1,2,\cdots,M)$, and $D(z)$ is the denominator polynomial of order N with roots $z_{p_k}, (k=1,2,\cdots,N)$. In general, we assume the order of the numerator polynomial is lower than that of the denominator polynomial, i.e., $M<N$. If this is not the case, we can always expand $X(z)$ into multiple terms so that $M<N$ is true for each of terms.

The "zeros" and "poles" of a rational $X(z)=N(z)/D(z)$ are defined as:

Definitions (#7.1.285):

D1. Each of the roots of the numerator polynomial z_z for which:

$$X(z)\Big|_{z=z_z}=X(z_z)=0 \tag{7.1.916}$$

is a "zero" of $X(z)$.

If the order of $D(z)$ exceeds that of $N(z)$ (i.e., $N>M$), then $X(+\infty)=0$, i.e., there is a zero at infinity:

$$\left.\frac{b_1z+b_0}{a_2z^2+a_1z+a_0}\right|_{z\to+\infty}=0 \tag{7.1.917}$$

D2. Each of the roots of the denominator polynomial z_p for which :

$$X(z)\Big|_{z=z_p}=X(z_p)=+\infty \tag{7.1.918}$$

is a "pole" of $X(z)$.

If the order of $N(z)$ exceeds that of $D(z)$ (i.e., $M>N$), then $X(+\infty)=+\infty$, i.e, there is a pole at infinity:

$$\left.\frac{b_2z^2+b_1z+b_0}{a_1z+a_0}\right|_{z\to+\infty}\to+\infty \tag{7.1.919}$$

Most essential behaviour properties of an LTI system can be obtained graphically from the ROC and the zeros and poles of its transfer function $H(z)$ on the z-plane.

7.1.5.3.5 Properties of $\mathcal{Z}$-Transform

The $\mathcal{Z}$-transform has a set of properties in parallel with that of the Fourier transform (and Laplace transform). The difference is that we need to pay special attention to the ROCs. In the following, we always assume:

$$\mathcal{Z}[x[n]]=X(z)\quad \text{ROC}=R_x \tag{7.1.920}$$

and:

$$\mathcal{Z}[y[n]]=Y(z)\quad \text{ROC}=R_y \tag{7.1.921}$$

- Linearity:

$$\mathcal{Z}[ax[n]+by[n]]=aX(z)+bY(z),\quad \text{ROC}\supseteq(R_x\cap R_y) \tag{7.1.922}$$

While it is obvious that the ROC of the linear combination of $x[n]$ and $y[n]$ should be the intersection of the their individual ROCs $R_x\cap R_y$ in which both $X(z)$ and $Y(z)$ exist, note that in some cases the ROC of the linear combination could be larger than $R_x\cap R_y$. For example, for both $x[n]=a^nu[n]$ and $y[n]=a^nu[n-1]$, the ROC is $|z|>|a|$, but the ROC of their difference $a^nu[n]-a^nu[n-1]=\delta[n]$ is the entire z-plane.

- Time shifting:

$$\mathcal{Z}[x[n-n_0]]=z^{-n_0}X(z),\quad \text{ROC}=R_x \tag{7.1.923}$$

Proof 7.3.27.

$$\mathcal{Z}[x[n-n_0]]=\sum_{n=-\infty}^{+\infty}x[n-n_0]z^{-n} \tag{7.1.924}$$

Define $m=n-n_0$, we have $n=m+n_0$ and:

$$\sum_{m=-\infty}^{+\infty}x[m]z^{-m}z^{-n_0}=z^{-n_0}X(z) \tag{7.1.925}$$

The new ROC is the same as the old one except the possible addition/deletion of the origin or infinity as the shift may change the duration of the signal.

■ Q.E.D.

A slightly different approach lead us to a different result that is more explicit and by the way more useful especially in business applications (we change the notation a bit to be in conformity with the tradition in the financial field). First let us consider the special case (shift of one unit only in the positive direction[9]):

$$\begin{aligned}\mathcal{Z}(f_{n+1})(z)&=\sum_{n=0}^{+\infty}f_{n+1}z^{-n}=z\sum_{n=0}^{+\infty}f_{n+1}z^{-(n+1)}=z\sum_{k=1}^{+\infty}f_kz^{-k}\\&=z\sum_{k=1}^{+\infty}f_kz^{-k}+(zf_0-zf_0)=z\left(\sum_{k=1}^{+\infty}f_kz^{-k}+f_0\right)-zf_0\\&=z\sum_{k=0}^{+\infty}f_kz^{-k}-zf_0=z\mathcal{Z}(f_n)(z)-zf_0\end{aligned} \tag{7.1.926}$$

---

[9] This is then a "unilateral $\mathcal{Z}$-transform" and as we will see it on page 2373, the properties then differ slightly from the bilateral version.

Repeating exactly the same type of procedure we get quite simply in the general way for $m>0$:

$$\begin{aligned}\mathcal{Z}(f_{n+1})(z)&=z^m\mathcal{Z}(f_n)(z)-z^mf_0-z^{m-1}f_1-\ldots-zf_{m-1}\\&=z^m\left[\mathcal{Z}(f_n)(z)-f_0-z^{-1}f_1-\ldots-z^{-m+1}f_{m-1}\right]\end{aligned}\tag{7.1.927}$$

- Time Expansion (Scaling):

$$\mathcal{Z}[x[n/k]]=X(z^k),\quad \text{ROC}=R_x^{1/k}\tag{7.1.928}$$

The discrete signal $x[n]$ cannot be continuously scaled in time as n has to be an integer (for a non-integer n $x[n]$ is zero). Therefore $x[n/k]$ is defined as:

$$x[n/k]\triangleq\begin{cases}x[n/k] & \text{if } n \text{ is a multiple of } k\\ 0 & \text{else}\end{cases}\tag{7.1.929}$$

✍**Example:**

If $x[n]$ is ramp:

n	1	2	3	4	5	6
$x[n]$	1	2	3	4	5	6

then the expanded version $x[n/2]$ is :

n	1	2	3	4	5	6
$n/2$	0.5	1	1.5	2	2.5	3
m		1		2		3
$x[n/2]$	0	1	0	2	0	3

where m is the integer part of n/k.

Proof 7.3.28. The $\mathcal{Z}$-transform of such an expanded signal is:

$$\mathcal{Z}[x[n/k]]=\sum_{n=-\infty}^{+\infty}x[n/k]z^{-n}=\sum_{m=-\infty}^{+\infty}x[m]z^{-km}=X(z^k)\tag{7.1.930}$$

Note that the change of the summation index from n to m has no effect as the terms skipped are all zeros.

■ Q.E.D.

- Convolution:

$$\mathcal{Z}[x[n]*y[n]]=X(z)Y(z),\quad \text{ROC}\supseteq(R_x\cap R_y)\tag{7.1.931}$$

The ROC of the convolution could be larger than the intersection of R_x and R_y, due to the possible pole-zero cancellation caused by the convolution.

- Time Difference:

$$\mathcal{Z}[x[n]-x[n-1]]=(1-z^{-1})X(z), \quad \text{ROC}=R_x \tag{7.1.932}$$

Proof 7.3.29.

$$\mathcal{Z}[x[n]-x[n-1]]=X(z)-z^{-1}X(z)=(1-z^{-1})X(z)=\frac{z-1}{z}X(z) \tag{7.1.933}$$

Note that due to the additional zero $z=1$ and pole $z=0$, the resulting ROC is the same as R_x except the possible deletion of $z=0$ caused by the added pole and/or addition of $z=1$ caused by the added zero which may cancel an existing pole.

■ Q.E.D.

- Time Accumulation:

$$\mathcal{Z}[\sum_{k=-\infty}^{n} x[k]]=\frac{1}{1-z^{-1}}X(z), \quad \text{ROC}\supseteq[R_x\cap(|z|>1)] \tag{7.1.934}$$

Proof 7.3.30. The accumulation of $x[n]$ can be written as its convolution with $u[n]$:

$$u[n]*x[n]=\sum_{k=-\infty}^{+\infty} u[n-k]x[k]=\sum_{k=-\infty}^{n} x[k] \tag{7.1.935}$$

Applying the convolution property, we get:

$$\mathcal{Z}[\sum_{k=-\infty}^{n} x[k]]=\mathcal{Z}[u[n]*x[n]]=\frac{1}{1-z^{-1}}X(z) \tag{7.1.936}$$

as $\mathcal{Z}[u[n]]=1/(1-z^{-1})$.

■ Q.E.D.

- Time Reversal:

$$\mathcal{Z}[x[-n]]=X(1/z) \quad \text{ROC}=1/R_x \tag{7.1.937}$$

Proof 7.3.31.

$$\mathcal{Z}[x[-n]]=\sum_{n=-\infty}^{+\infty} x[-n]z^{-n}=\sum_{m=-\infty}^{+\infty} x[m]\left(\frac{1}{z}\right)^{-m}=X(1/z) \tag{7.1.938}$$

where $m=-n$.

■ Q.E.D.

- Scaling in z-domain:

$$\mathcal{Z}[a^n x[n]]=X\left(\frac{z}{a}\right), \quad \text{ROC}=|a|R_x \tag{7.1.939}$$

Proof 7.3.32.

$$\mathcal{Z}[a^n x[n]] = \sum_{n=-\infty}^{+\infty} x[n] \left(\frac{z}{a}\right)^{-n} = X\left(\frac{z}{a}\right) \tag{7.1.940}$$

In particular, if $a = e^{\mathrm{i}\omega_0}$, the above becomes:

$$\mathcal{Z}[e^{jn\omega_0} x[n]] = X(e^{-\mathrm{i}\omega_0} z) \quad \text{ROC} = R_x \tag{7.1.941}$$

The multiplication by $e^{-\mathrm{i}\omega_0}$ to z corresponds to a rotation by angle ω_0 in the z-plane, i.e., a frequency shift by ω_0. The rotation is either clockwise ($\omega_0 > 0$) or counter clockwise ($\omega_0 < 0$) corresponding to, respectively, either a left-shift or a right shift in frequency domain. The property is essentially the same as the frequency shifting property of discrete Fourier transform.

■ Q.E.D.

- Conjugation:

$$\mathcal{Z}[x^*[n]] = X^*(z^*), \quad \text{ROC} = R_x \tag{7.1.942}$$

Proof 7.3.33. Complex conjugate of the $\mathcal{Z}$-transform of $x[n]$ is:

$$X^*(z) = [\sum_{n=-\infty}^{+\infty} x[n] z^{-n}]^* = \sum_{n=-\infty}^{+\infty} x^*[n](z^*)^{-n} \tag{7.1.943}$$

Replacing z by z^*, we get the desired result.

■ Q.E.D.

- Differentiation in z-domain:

$$\mathcal{Z}[nx[n]] = -z\frac{\mathrm{d}}{\mathrm{d}z} X(z), \quad \text{ROC} = R_x \tag{7.1.944}$$

Proof 7.3.34.

$$\frac{\mathrm{d}}{\mathrm{d}z} X(z) = \sum_{n=-\infty}^{+\infty} x[n] \frac{\mathrm{d}}{\mathrm{d}z}(z^{-n}) = \sum_{n=-\infty}^{+\infty} (-n) x[n] z^{-n-1} = \frac{-1}{z} \sum_{n=-\infty}^{+\infty} n x[n] z^{-n} \tag{7.1.945}$$

i.e.:

$$\mathcal{Z}[nx[n]] = -z\frac{\mathrm{d}}{\mathrm{d}z} X(z) \tag{7.1.946}$$

■ Q.E.D.

✍**Example:**

Taking derivative with respect to z of the right side of:

$$\mathcal{Z}[a^n u[n]] = \frac{1}{1-az^{-1}} \quad |z|>|a| \tag{7.1.947}$$

we get:

$$\frac{\mathrm{d}}{\mathrm{d}z}\left[\frac{1}{1-az^{-1}}\right] = \frac{-az^{-2}}{(1-az^{-1})^2} \tag{7.1.948}$$

Due to the property of differentiation in z-domain, we have:

$$\mathcal{Z}[na^n u[n]] = \frac{az^{-1}}{(1-az^{-1})^2} \quad |z|>|a| \tag{7.1.949}$$

Note that for a different ROC $|z|<|a|$, we have:

$$\mathcal{Z}[-na^n u[-n-1]] = \frac{az^{-1}}{(1-az^{-1})^2} \quad |z|<|a| \tag{7.1.950}$$

7.1.5.3.6 Usual $\mathcal{Z}$-Transforms

As we always do in this textbook, let us see some common usual $\mathcal{Z}$-Transforms that are useful in engineering in some well known problems:

1. $\delta[n]$, $\delta[n-m]$

$$\mathcal{Z}[\delta[n]] = \sum_{n=-\infty}^{+\infty} \delta[n]z^{-n} = \delta[0]z^{-0} = \delta[0] = 1 \qquad \forall z \tag{7.1.951}$$

Due to the time shifting property, we also have:

$$\mathcal{Z}[\delta[n-m]] = z^{-m} \qquad \forall z \tag{7.1.952}$$

2. $u[n]$, $a^n u[n]$, $na^n u[n]$

$$\mathcal{Z}[u[n]] = \sum_{n=0}^{+\infty} z^{-n} = \frac{1}{1-z^{-1}} = \frac{z}{z-1} \qquad |z|>1 \tag{7.1.953}$$

Due to the scaling in z-domain property, we have:

$$\mathcal{Z}[a^n u[n]] = \frac{1}{1-(z/a)^{-1}} = \frac{1}{1-az^{-1}} \qquad S|z|>|a| \tag{7.1.954}$$

Or for those that don't like using this property, we have simply using the previous result:

$$\mathcal{Z}[a^n u[n]] = \sum_{n=0}^{+\infty} a^n z^{-n} = \sum_{n=0}^{+\infty}(a^{-1}z)^{-n} = \frac{1}{1-(z/a)^{-1}} = \frac{\frac{z}{a}}{\frac{z}{a}-1} = \frac{z}{z-a} \tag{7.1.955}$$

Applying the property of differentiation in z-domain to the above, we have:

$$\mathcal{Z}[na^n u[n]]=-z\frac{\mathrm{d}}{\mathrm{d}z}\left[\frac{1}{1-az^{-1}}\right]=-z\frac{-az^{-2}}{(1-az^{-1})^2}=\frac{az^{-1}}{(1-az^{-1})^2}\qquad |z|>|a| \tag{7.1.956}$$

3. $u[n-k]$

   Using the time shifting property that is for recall given by:

$$\mathcal{Z}(x[n-n_0])=z^{-n_0}X(z) \tag{7.1.957}$$

   we have:

$$\mathcal{Z}(u[n-k])=z^{-k}X(u[n])=z^{-k}\frac{z}{z-1}=\frac{z^{1-k}}{z-1} \tag{7.1.958}$$

✍**Example:**

A useful case for a simple business application that we will use later is:

$$\mathcal{Z}(u[n-k])=\mathcal{Z}(u[n-l-1])=\mathcal{Z}(u[n-(l+1)])=\frac{z^{2-l}}{z-1} \tag{7.1.959}$$

4. $e^{\pm in\omega_0}u[n]$, $\cos[n\omega_0]u[n]$, $\sin[n\omega_0]u[n]$

   Applying the scaling in z-domain property to $\mathcal{Z}[u[n]]=1/(1-z^{-1})$, we have:

$$\mathcal{Z}[e^{in\omega_0}u[n]]=\frac{1}{1-(e^{\mathrm{i}\omega_0}z)^{-1}}=\frac{1}{1-e^{-\mathrm{i}\omega_0}z^{-1}}\qquad |z|>1 \tag{7.1.960}$$

   and similarly, we have:

$$\mathcal{Z}[e^{-in\omega_0}u[n]]=\frac{1}{1-e^{\mathrm{i}\omega_0}z^{-1}}\qquad |z|>1 \tag{7.1.961}$$

   Moreover, we have:

$$\begin{aligned}\mathcal{Z}[\cos(n\omega_0)u[n]]=\mathcal{Z}\left[\frac{e^{in\omega_0}+e^{-in\omega_0}}{2}u[n]\right]&=\frac{1}{2}\left[\frac{1}{1-e^{\mathrm{i}\omega_0}z^{-1}}+\frac{1}{1-e^{-\mathrm{i}\omega_0}z^{-1}}\right]\\&=\frac{2-(e^{\mathrm{i}\omega_0}+e^{-\mathrm{i}\omega_0})z^{-1}}{2[1-(e^{\mathrm{i}\omega_0}+e^{-\mathrm{i}\omega_0})z^{-1}+z^{-2}]}\\&=\frac{1-\cos(\omega_0)z^{-1}}{1-2\cos(\omega_0)z^{-1}+z^{-2}}\qquad |z|>1\end{aligned} \tag{7.1.962}$$

   Similarly we have:

$$\mathcal{Z}[\sin(n\omega_0)u[n]]=\frac{\sin\left(\omega_0 z^{-1}\right)}{1-2\cos\left(\omega_0 z^{-1}\right)+z^{-2}}\qquad |z|>1 \tag{7.1.963}$$

5. $r^n\cos[n\omega_0]u[n]$, $r^n\sin[n\omega_0]u[n]$

Applying the z-domain scaling property to the above, we have:

$$\mathcal{Z}[r^n \cos(n\omega_0)u[n]] = \frac{1 - r\ \cos\left(\omega_0 z^{-1}\right)}{1 - 2r\ \cos\left(\omega_0 z^{-1}\right) + r^2 z^{-2}} \qquad |z| > r \tag{7.1.964}$$

and:

$$\mathcal{Z}[r^n \sin(n\omega_0)u[n]] = \frac{r\ \sin\left(\omega_0 z^{-1}\right)}{1 - 2r\ \cos\left(\omega_0 z^{-1}\right) + r^2 z^{-2}} \qquad |z| > r \tag{7.1.965}$$

To summarize:

$x[n]$	$X(z) = \mathcal{Z}(x[n])$	**ROC**
$A\delta[n]$	A	Everywhere
$A\delta\left[n - n_0\right]$	Az^{-n_0}	Everywhere
$A \cdot u[n]$	$\frac{A}{1-z^{-1}} = \frac{Az}{z-1}$	$\lvert z\rvert > 1$
$u[n-k]$	$\frac{z^{1-k}}{z-1}$	$\lvert z\rvert > 1$
$Aa^n \cdot u[n]$	$\frac{A}{1-az^{-1}} = \frac{Az}{z-a}$	$\lvert z\rvert > \lvert a\rvert$

$Aa^n e^{\mathrm{i}\omega n} \cdot u[n]$	$\frac{A}{1-ae^{j\omega}z^{-1}} = \frac{Az}{z-ae^{j\omega}}$	$\lvert z\rvert > \lvert a\rvert$
$Aa^n \cos(\omega n) \cdot u[n]$	$\frac{Az(z-a\cos\omega)}{z^2-(2a\cos\omega)z+a^2}$	$\lvert z\rvert > \lvert a\rvert$
$Aa^n \cos(\omega n + \alpha) \cdot u[n]$	$\frac{\frac{A}{2}e^{j\alpha}}{1-ae^{\mathrm{i}\omega}z^{-1}} + \frac{\frac{A}{2}e^{-j\alpha}}{1-ae^{-j\omega}z^{-1}}$	$\lvert z\rvert > \lvert a\rvert$
$A\cos(\omega n) \cdot u[n]$	$\frac{Az(z-\cos\omega)}{z^2-(2\cos\omega)z+1}$	$\lvert z\rvert > 1$
$A\sin(\omega n) \cdot u[n]$	$\frac{Az\sin\omega}{z^2-(2\cos\omega)z+1}$	$\lvert z\rvert > 1$
$An \cdot u[n]$	$\frac{Az^{-1}}{(1-z^{-1})^2} = \frac{Az}{(z-1)^2}$	$\lvert z\rvert > 1$
$An^2 \cdot u[n]$	$\frac{Az^{-1}\left(1+z^{-1}\right)}{(1-z^{-1})^3} = \frac{Az(z+1)}{(z-1)^2}$	$\lvert z\rvert > 1$
$Ana^n \cdot u[n]$	$\frac{Aaz^{-1}}{(1-az^{-1})^2} = \frac{Aaz}{(z-a)^2}$	$\lvert z\rvert > \lvert a\rvert$
$Aa^n \cdot u[-n-1]$	$\frac{-A}{1-az^{-1}} = \frac{-Az}{z-a}$	$\lvert z\rvert < \lvert a\rvert$

Table 7.11: **Most common $\mathcal{Z}$-Transforms**

7.1.5.3.7 Unilateral $\mathcal{Z}$-Transform

The "unilateral $\mathcal{Z}$-transform" of an arbitrary signal $x[n]$ is defined as:

$$\boxed{\mathcal{UZ}[x[n]] = X(z) \triangleq \sum_{n=-\infty}^{+\infty} x[n]u[n]z^{-n} = \sum_{n=0}^{+\infty} x[n]z^{-n}} \tag{7.1.966}$$

where for recall $\mathcal{U}$ and $u[n]$ are another typical notation of the Heaviside function.

Some of the properties of the unilateral $\mathcal{Z}$-transform that differ slightly from the bilateral $\mathcal{Z}$-transform are listed below:

P1. Time Advance:

$$\begin{aligned}\mathcal{UZ}\left[x[n+1]\right] &= \sum_{n=0}^{+\infty} x[n+1]z^{-n} = z\sum_{m=1}^{+\infty} x[m]z^{-m} \\ &= z\left[\sum_{m=0}^{+\infty} x[m]z^{-m} - x[0]\right] = zX(z) - zx[0]\end{aligned} \tag{7.1.967}$$

where we have assumed $m = n+1$.

P2. Time Delay:

$$\begin{aligned}\mathcal{UZ}\left[x[n-1]\right] &= \sum_{n=0}^{+\infty} x[n-1]z^{-n} = z^{-1}\sum_{m=-1}^{+\infty} x[m]z^{-m} \\ &= z^{-1}\left[\sum_{m=0}^{+\infty} x[m]z^{-m} + zx[-1]\right] = z^{-1}X(z) + x[-1]\end{aligned} \tag{7.1.968}$$

where $m = n-1$. Similarly, we have:

$$\begin{aligned}\mathcal{UZ}[x[n-2]] &= \sum_{n=0}^{+\infty} x[n-2]z^{-n} = z^{-2}\sum_{m=-2}^{+\infty} x[m]z^{-m} \\ &= z^{-2}\left[\sum_{m=0}^{+\infty} x[m]z^{-m} + zx[-1] + z^2x[-2]\right] \\ &= z^{-2}X(z) + x[-1]z^{-1} + x[-2]\end{aligned} \tag{7.1.969}$$

where $m = n-2$. In general, we have:

$$\mathcal{UZ}[x[n-n_0]] = z^{-n_0}X(z) + \sum_{k=0}^{n_0-1} z^{-k}x[k-n_0] \tag{7.1.970}$$

P3. Convolution:

$$\mathcal{UZ}[x[n]*y[n]] = X(z)Y(z) \tag{7.1.971}$$

If both $x[n]$ and $y[n]$ are causal, i.e., $x[n] = y[n] = 0$ for $n < 0$, the unilateral and bilateral $\mathcal{Z}$ transforms are identical.

P4. Time Difference:

$$\mathcal{UZ}[x[n] - x[n-1]] = (1-z^{-1})X(z) \quad \text{ROC} = R_x \tag{7.1.972}$$

Proof 7.3.35.

$$\mathcal{UZ}[x[n] - x[n-1]] = X(z) - z^{-1}X(z) - x[-1] = (1-z^{-1})X(z) - x[-1] \tag{7.1.973}$$

■ Q.E.D.

P5. Time Accumulation:

$$\mathcal{UZ}\left[\sum_{k=0}^{n} x[k]\right] = \frac{1}{1-z^{-1}}X(z) = \frac{z}{z-1}X(z) \tag{7.1.974}$$

P6. Initial Value Theorem:

If $x[n]=x[n]u[n]$, i.e., $x[n]=0$ for $n<0$, then:

$$x[0]=\lim_{z\rightarrow+\infty}X(z) \tag{7.1.975}$$

Proof 7.3.36.

$$\lim_{z\rightarrow+\infty}X(z)=\lim_{z\rightarrow+\infty}\left[\sum_{n=0}^{+\infty}x[n]z^{-n}\right]=x[0] \tag{7.1.976}$$

All terms with $n>0$ become zero as $z^{-n}=1/z^{n}\rightarrow 0$ as $z\rightarrow+\infty$, except the first one which is always $x[0]$.

■ Q.E.D.

P7. Final Value Theorem:

If $x[n]=x[n]u[n]$, i.e., $x[n]=0$ for $n<0$, then:

$$\lim_{n\rightarrow+\infty}x[n]=x[+\infty]=\lim_{z\rightarrow 1}(1-z^{-1})X(z) \tag{7.1.977}$$

Proof 7.3.37.

$$\mathcal{Z}\left[x[n]-x[n-1]\right]=X(z)-X(z)z^{-1}=\sum_{n=0}^{+\infty}\left[x[n]-x[n-1]\right]z^{-n} \tag{7.1.978}$$

i.e.:

$$(1-z^{-1})X(z)=\lim_{N\rightarrow+\infty}\sum_{n=0}^{N}\left[x[n]-x[n-1]\right]z^{-n} \tag{7.1.979}$$

Letting $z\rightarrow 1$ in the above, we get:

$$\begin{aligned}\lim_{z\rightarrow 1}(1-z^{-1})X(z)&=\lim_{N\rightarrow+\infty}\left[\sum_{n=0}^{N}[x[n]-x[n-1]\right]\lim_{N\rightarrow+\infty}[x[N]-x[-1]]\\&=\lim_{N\rightarrow+\infty}x[N]=x[+\infty]\end{aligned} \tag{7.1.980}$$

where $x[-1]=0$.

7.1.5.4 Hilbert Transform

The information about the Hilbert transform is often scattered in most textbooks about signal processing. Their authors frequently use mathematical formulas without explaining them thoroughly to the reader at the opposite of the Fourier, Laplace or $\mathcal{Z}$-transform. Our purpose is to make a more stringent presentation of the Hilbert transform but still with the signal processing application in mind.

Definition (#7.1.286): The "Hilbert transform" of a function $f(t)$ is defined for all t by:

$$\boxed{X(t)=\frac{1}{\pi}\mathrm{P}\int\limits_{-\infty}^{+\infty}\frac{f(\tau)}{t-\tau}\mathrm{d}\tau} \qquad (7.1.981)$$

when the integral exists.

It is normally not possible to calculated the Hilbert transform as an ordinary improper integral because of the pole at $\tau=t$. However, the P in front of the integral denotes the "Cauchy principal value" which expanding the class of function for which the integral definition above exist. It can be defined as following:

Definition (#7.1.287): The "Cauchy principal value" is a method for assigning values to certain improper integrals (see section Differential and Integral Calculus page 1595) which would otherwise be undefined. Depending on the type of singularity in the integrand f, the Cauchy principal value is defined according to the following rules:

- For a singularity at the finite number b:

$$\lim_{\varepsilon\to 0^+}\left[\int\limits_a^{b-\varepsilon} f(x)\mathrm{d}x+\int\limits_{b+\varepsilon}^{c} f(x)\mathrm{d}x\right] \qquad (7.1.982)$$

  where b is a point at which the behaviour of the function f is such that:

$$\begin{gathered}\int\limits_a^b f(x)\mathrm{d}x=\pm\infty \text{ for any } a<b \text{ and}\\ \int_b^c f(x)\mathrm{d}x=\mp\infty \text{ for any } c>b\end{gathered} \qquad (7.1.983)$$

- For a singularity at infinity:

$$\lim_{a\to+\infty}\int\limits_{-a}^{a} f(x)\mathrm{d}x \qquad (7.1.984)$$

  where:

$$\int\limits_{-\infty}^{0} f(x)\mathrm{d}x=\pm\infty \qquad \text{and} \qquad \int\limits_{0}^{+\infty} f(x)\mathrm{d}x=\mp\infty \qquad (7.1.985)$$

In some cases it is necessary to deal simultaneously with singularities both at a finite number b and at infinity. This is usually done by a limit of the form:

$$\lim_{\varepsilon\to 0+}\left[\int\limits_{b-\frac{1}{\varepsilon}}^{b-\varepsilon} f(x)\mathrm{d}x+\int\limits_{b+\varepsilon}^{b+\frac{1}{\varepsilon}} f(x)\mathrm{d}x\right] \tag{7.1.986}$$

The Cauchy principal value can also be defined in terms of contour integrals of a complex-valued function $f(z);\, z=x+\mathrm{i}y$, with a pole on a contour C. Define $C(\varepsilon)$ to be the same contour where the portion inside the disk of radius ε around the pole has been removed. Provided the function $f(z)$ is integrable over $C(\varepsilon)$ no matter how small ε becomes, then the Cauchy principal value is the limit:

$$\mathrm{P}\int\limits_{C} f(z)\mathrm{d}z=\lim_{\varepsilon\to 0+}\int\limits_{C(\varepsilon)} f(z)\mathrm{d}z \tag{7.1.987}$$

✍**Example:**

Consider the ill-defined expression:

$$\int\limits_{-1}^{+1}\frac{\mathrm{d}x}{x} \tag{7.1.988}$$

As the primitive of $1/x$ is equal to $\ln(x)$ there is obviously a problem... So the idea is to write instead:

$$\lim_{a\to 0+}\left(\int\limits_{-1}^{-a}\frac{\mathrm{d}x}{x}+\int\limits_{a}^{+1}\frac{\mathrm{d}x}{x}\right) \tag{7.1.989}$$

but as the $1/x$ function is odd, we can write this:

$$\lim_{a\to 0+}\left(-\int\limits_{a}^{+1}\frac{\mathrm{d}x}{x}+\int\limits_{a}^{+1}\frac{\mathrm{d}x}{x}\right)=\lim_{a\to 0+}(0) \tag{7.1.990}$$

that is obviously equal to 0! So 0 is the principal value of the initial integral.

Remark

Sadly different authors use different notations for the Cauchy principal value of a function f, among others:

$$P\int f(x)\mathrm{d}x,\, PV\int f(x)\mathrm{d}x,\, \text{p.v.}\int f(x)\mathrm{d}x,\, \text{P.V.}\int f(x)\mathrm{d}x,\, \mathcal{P}\int f(x)\mathrm{d}x,\, P_v\int f(x)\mathrm{d}x,\, \int_L^{*} f(z)\mathrm{d}z,\, ⨍ f(x)\mathrm{d}x,\ldots$$

7.1.6 Functional dot product (inner product)

The "functional dot product" (very strong analogy with the dot product in seen in the section Vector Calculus) may seem unnecessary when examined for the first time outside of an application context or only as generalization purpose, but in fact it has many practical applications. We will make such direct use in the section of Wave Quantum Physics and Quantum Chemistry, or even more important in the context of trigonometric polynomials through the Fourier series and transforms (see section Sequences and Series page 1727) that we find everywhere in contemporary physics and computer science.

However, if the reader has not travelled the section of Vector Calculus and the part treating the vector dot product, we would highly recommend reading it otherwise what follows may be a little incomprehensible.

We put ourselves in the space $\mathcal{C}([a,b],\mathbb{R})$ of continuous functions in the interval $[a,b]$ into $\mathbb{R}$ with the inner product defined by (we find here again the specific notation of the dot product in its functional - i.e. integral - version as we had mentioned during our definition of the vector dot product in the section of Vector Calculus):

$$\boxed{\langle f|g\rangle=\int\limits_a^b f(x)\cdot g(x)\mathrm{d}x} \tag{7.1.991}$$

A family of orthogonal polynomials, as we can make the analogy with the dot product in the section Vector Calculus, is therefore a polynomial family $(p_0,\ldots,p_n,\ldots)$ such as:

$$\langle p_j|p_k\rangle=0 \tag{7.1.992}$$

if $j\neq k$. We recall that an orthogonal family is a free family. We also saw in the section of Vector Calculus that in the space $\mathcal{C}([a,b],\mathbb{C})$ the only possible coherent choice was:

$$\boxed{\langle f|g\rangle=\int\limits_a^b f(x)\cdot \overline{g(x)}\mathrm{d}x} \tag{7.1.993}$$

We name the two previous relations "L^2-dot product".

Remember now that if we want to show something is an inner product, we need to show three things for all $f,g\in\mathbb{R}^2$ and $\alpha\in\mathbb{R}$:

1. Symmetry: $\langle f|g\rangle=\langle g|f\rangle$ (or, if the field is the complex numbers $\mathbb{C}^n$, $\langle f|g\rangle=\overline{\langle g|f\rangle}$, i.e. "conjugate symmetry)
2. Linearity: $\langle \alpha f|g\rangle=\alpha\langle f|g\rangle$. Notice this also implies $\langle f|\alpha g\rangle=\alpha\langle f|g\rangle$ ($\bar{\alpha}$ in the complex case) by symmetry
3. Positive-definite: $\langle f,f\rangle\geq 0$ with equality if and only if $f=0$, the zero function

The first two properties follow directly from the definition of an integral. For the third property, it's quite obvious (the integral of f^2 can be zero only if f is zero).

Remark

If such a dot product exist, we can then the Cauchy-Schwarz inequality also applies to it. We name it the "Cauchy-Schwarz inequality for integrals".

Therefore we can build the "L^2-norm":

$$\|f\|_{L^2}=\sqrt{\langle f|g\rangle}=\left(\int_a^b f(x)\cdot\overline{g(x)}\mathrm{d}x\right)^{1/2} \tag{7.1.994}$$

Remark

We will see further below that the definition above is not the most general one as especially physicists and engineers say that functions are orthogonal under a more constraint situation!

The development that will follow will remind us the Gram-Schmidt procedure (see section Vector Calculus page 2062) to build an orthogonal family.

Theorem 7.4. Given $(p_0,\ldots,p_n,\ldots)$ a family of linearly independent polynomial defined on $[a,b]$ and V the vector space defined by this family. The family $(y_0,\ldots,y_n,\ldots)$ defined by recurrence in the following way:

$$y_n=p_n-\sum_{j=0}^{n-1}\langle p_n|y_j\rangle\frac{y_j}{\|y_j\|^2}\text{ for }n>1 \tag{7.1.995}$$

and $y_0=p_0$ is orthogonal and generates V.

Proof 7.4.1. Let us show by induction on n that $(y_0,y\ldots,y_n,\ldots)$ is an orthogonal family which generates the same space as $(p_0,\ldots,p_n,\ldots)$. The assertion holds for $n=0$. Let us suppose that the assertion holds for $n\geq 0$, for $0\leq k\leq n$ we have:

$$\begin{aligned}\langle y_{n+1}|y_k\rangle&=\left\langle p_{n+1}-\sum_{j=0}^{n}\langle p_{n+1}|y_j\rangle\cdot\frac{y_j}{\|y_j\|^2}\middle|y_k\right\rangle=\langle p_{n+1}|y_k\rangle-\sum_{j=0}^{n}\langle p_{n+1}|y_j\rangle\cdot\langle y_j|y_k\rangle\cdot\frac{1}{\|y_j\|^2}\\&=\langle p_{n+1}|y_k\rangle-\langle p_{n+1}|y_k\rangle\cdot\langle y_k|y_k\rangle\cdot\frac{1}{\|y_k\|^2}=\langle p_{n+1}|y_k\rangle-\langle p_{n+1}|y_k\rangle=0\end{aligned} \tag{7.1.996}$$

$(y_0,\ldots,y_n,\ldots)$ is therefore orthogonal. Finally, we get the equality:

$$y_{n+1}=p_{n+1}-\sum_{j=0}^{n}\langle p_{n+1}|y_j\rangle\cdot\frac{y_j}{\|y_j\|^2} \tag{7.1.997}$$

■ Q.E.D.

Let us see a first example very important is signal processing and statistics that is relatively to frequency analysis:

✍**Example:**

Let us consider the very important example in modern physics that is the set of continuous 2π-periodic function denoted $P_{2\pi}$ that forms a vector space (see section Set Theory page 1805).

We define the dot product of two functions of this set by:

$$\forall f,g\in P_{2\pi}\quad \langle f|g\rangle=\int\limits_{-\pi}^{\pi} f(x)g(x)\mathrm{d}x=\int\limits_{0}^{-\pi} f(x)g(x)\mathrm{d}x \tag{7.1.998}$$

The aim of this definition is to build an abstract functional basis $P_{2\pi}$ on which we can break down any 2π-periodic function!!!

The simplest idea is then to use the trigonometric functions sine and cosine:

$$\begin{gathered}\cos(x),\cos(2x),\cos(3x),\ldots,\cos(nx)\\ \sin(x),\sin(2x),\sin(3x),\ldots,\sin(nx)\end{gathered} \tag{7.1.999}$$

The relations below show that the basis chosen above are orthogonal and therefore form a free family, plus it's a generating family of the vector space $P_{2\pi}$ because as we have seen in our study of Fourier series (see section Sequences and Series page 1727) we have the following values:

$$\begin{gathered}\int\limits_{0}^{2\pi}\cos(kx)\cos(mx)\mathrm{d}x=\delta_{km}\pi\\ \int\limits_{0}^{2\pi}\sin(kx)\sin(mx)\mathrm{d}x=\delta_{km}\pi\\ \int\limits_{0}^{2\pi}\cos(kx)\sin(mx)\mathrm{d}x=0\end{gathered} \tag{7.1.1000}$$

where δ_{km} is the kronecker symbol (see section Tensor Calculus page 2044).

Therefore it is also an orthogonal basis but not orthonormal. If we want to normalized the vectors of the basis we just need obviously to take:

$$\begin{gathered}\frac{1}{\sqrt{\pi}}\cos(x),\frac{1}{\sqrt{\pi}}\cos(2x),\frac{1}{\sqrt{\pi}}\cos(3x),\ldots,\frac{1}{\sqrt{\pi}}\cos(nx)\\ \frac{1}{\sqrt{\pi}}\sin(x),\frac{1}{\sqrt{\pi}}\sin(2x),\frac{1}{\sqrt{\pi}}\sin(3x),\ldots,\frac{1}{\sqrt{\pi}}\sin(nx)\end{gathered} \tag{7.1.1001}$$

Remark

If the reader remembers that for a random variable X defined on $\mathbb{R}$, the mean was calculated as (see section Statistics page 634):

$$\mathrm{E}(X)=\int\limits_{-\infty}^{+\infty} xf(x)\mathrm{d}x \qquad (7.1.1002)$$

Then we can assimilate:

$$\mathrm{E}(g(x))=\int\limits_{-\infty}^{+\infty} g(x)f(x)\mathrm{d}x \qquad (7.1.1003)$$

where:

$$\int\limits_{-\infty}^{+\infty} f(x)\mathrm{d}x=1 \qquad (7.1.1004)$$

to the expected mean of the function $g(x)$! Analogy sometimes very useful in practice!

Let us see now another example that is an extension of the previous one and that has also a great importance in signal processing but also in quantum physics and quantum chemistry:

✍**Example:**

Let us consider a basis of complex functions of the form $re^{\mathrm{i}n\varphi}$ with $n\in\mathbb{Z}$. We therefore can write:

$$\langle ae^{\mathrm{i}m\varphi}|be^{\mathrm{i}m\varphi}\rangle=\int\limits_{-\pi}^{+\pi} ae^{\mathrm{i}m\varphi}\cdot\overline{be^{\mathrm{i}n\varphi}}\mathrm{d}\varphi=ab\int\limits_{-\pi}^{+\pi} e^{\mathrm{i}(m-n)\varphi}\mathrm{d}\varphi \qquad (7.1.1005)$$

We get:

$$ab\int\limits_{-\pi}^{+\pi} e^{\mathrm{i}(m-n)\varphi}\mathrm{d}\varphi=\begin{cases} ab\displaystyle\int\limits_{-\pi}^{+\pi} 1\mathrm{d}x=ab2\pi & m=n \\ ab\left[\dfrac{-\mathrm{i}}{m-n}e^{\mathrm{i}(m-n)\varphi}\right]_{-\pi}^{+\pi}=0 & m\neq n \end{cases} \qquad (7.1.1006)$$

It is obvious that if we take for basis functions of the type:

$$\varphi_n=\frac{1}{2\pi}e^{\mathrm{i}n\varphi} \qquad (7.1.1007)$$

then we have an orthonormal basis (and not just an orthogonal one).

Let us see again another example that will be useful for us in the section of Wave Mechanics for our study of the ideal circular membrane of a drum.

✍**Example:**

We have proved in the section Sequences and Series that the Bessel function (see page 1768) $J_p(x)$ satisfies the following differential equation (Bessel's equation):

$$x^2\frac{\mathrm{d}^2 J_p}{\mathrm{d}x^2}+x\frac{\mathrm{d}J_p}{\mathrm{d}x}+(x^2-p^2)J_p=0 \tag{7.1.1008}$$

which can be written as:

$$x\frac{\mathrm{d}}{\mathrm{d}x}\left(x\frac{\mathrm{d}J_p}{\mathrm{d}x}\right)+(x^2-p^2)J_p=0 \tag{7.1.1009}$$

The variable p need not be an integer as we will see it in the section of Mechanical Engineering with the study case of the self-buckling column.

It turns out to be useful to define a new variable t by $x=at$, where a is a constant which we will take to be a zero of J_p, i.e. $J_p(a)=0$. Let us define:

$$u(t)=J_p(at) \tag{7.1.1010}$$

which implies:

$$u(1)=0 \tag{7.1.1011}$$

and substituting into (7.1.1009) gives:

$$t\frac{\mathrm{d}}{\mathrm{d}t}\left(t\frac{\mathrm{d}u}{\mathrm{d}t}\right)+(a^2t^2-p^2)u=0 \tag{7.1.1012}$$

since $x\mathrm{d}/\mathrm{d}x$ is equivalent to $t\mathrm{d}/\mathrm{d}t$.

We can also write down the equation obtained by picking another zero, b. Defining:

$$v(t)=J_p(bt) \tag{7.1.1013}$$

which implies:

$$v(1)=0 \tag{7.1.1014}$$

we have then:

$$t\frac{\mathrm{d}}{\mathrm{d}t}\left(t\frac{\mathrm{d}v}{\mathrm{d}t}\right)+(b^2t^2-p^2)v=0 \tag{7.1.1015}$$

To derive the orthogonality relation, we multiply (7.1.1012) by v, and (7.1.1015) by u. Subtracting and dividing by t gives:

$$v\frac{\mathrm{d}}{\mathrm{d}t}\left(t\frac{\mathrm{d}u}{\mathrm{d}t}\right)-u\frac{\mathrm{d}}{\mathrm{d}t}\left(t\frac{\mathrm{d}v}{\mathrm{d}t}\right)+(a^2-b^2)tuv=0 \tag{7.1.1016}$$

The first two terms in (7.1.1016) can be combined as:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(vt\frac{\mathrm{d}u}{\mathrm{d}t}-ut\frac{\mathrm{d}v}{\mathrm{d}t}\right) \tag{7.1.1017}$$

since the extra terms present in (7.1.1017), but not in (7.1.1016), when the derivatives are expanded out are equal and opposite and so cancel. Hence we have:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(vt\frac{\mathrm{d}u}{\mathrm{d}t}-ut\frac{\mathrm{d}v}{\mathrm{d}t}\right)+(a^2-b^2)tuv=0 \tag{7.1.1018}$$

We next integrate this over the range of t from 0 to 1 (0 since the Bessel function is not defined for $t<0$ and to 1 since it's the place where there is a zero by construction for recall!), which gives:

$$\left[vt\frac{\mathrm{d}u}{\mathrm{d}t}-ut\frac{\mathrm{d}v}{\mathrm{d}t}\right]_0^1+(a^2-b^2)\int_0^1 tu(t)v(t)\mathrm{d}t=0 \tag{7.1.1019}$$

The integrated term vanishes at the lower limit because $t=0$, and it also vanishes at the upper limit because $u(1)=v(1)=0$, see (7.1.1011) and (7.1.1013). Hence, if $a\neq b$, (7.1.1019) gives:

$$\int_0^1 tu(t)v(t)\mathrm{d}t=0 \tag{7.1.1020}$$

which, using (7.1.1010) and (7.1.1013), can be written:

$$\boxed{\int_0^1 tJ_p(at)J_p(bt)\mathrm{d}t=0} \tag{7.1.1021}$$

This is the desired orthogonality equation! Remember we require that a and b are distinct zeroes of J_p, so both Bessel functions in (7.1.1021) vanish at the upper limit.

Let us see again another another example that will be useful for us in the section of Wave Quantum Physics during our study of the harmonic oscillator (see page 4817):

✍**Example:**

We will introduce in the section of Wave Quantum Physics the following "physicist Hermite polynomial":

$$H_n(x)=(-1)^n e^{x^2}\frac{\mathrm{d}^n}{\mathrm{d}x^n}e^{-x^2} \tag{7.1.1022}$$

Therefore (see the plot in the section of Wave Quantum Physics at page 4817):

$$\begin{aligned}
&H_0=1\\
&H_1=2x\\
&H_2=4x^2-2\\
&H_3=8x^3-12x\\
&H_4=16x^4-48x+12\\
&H_5=32x^5-160x^3+120x\\
&H_6=64x^6-480x^4+720x^2-120\\
&\ldots
\end{aligned} \tag{7.1.1023}$$

where we notice almost immediately that (useful for further below):

$$\frac{\mathrm{d}^n}{\mathrm{d}x^n}H_n=2^n n! \tag{7.1.1024}$$

And we need to prove that they are orthogonal (or even better: orthonormal!).

For this purpose we introduce the weight function $w(x)=e^{-x^2}$, therefore:

$$\begin{aligned}
\int\limits_{-\infty}^{+\infty}H_n(x)H_m(x)\,\mathrm{e}^{-x^2}\,\mathrm{d}x&=(-1)^m\int\limits_{-\infty}^{+\infty}\left(\frac{\mathrm{d}^m}{\mathrm{d}x^m}\mathrm{e}^{-x^2}\right)H_n(x)\mathrm{d}x\\
&=(-1)^{m-n}\int\limits_{-\infty}^{+\infty}\left(\frac{\mathrm{d}^{m-n}}{\mathrm{d}x^{m-n}}\mathrm{e}^{-x^2}\right)H_n^{(n)}(x)\mathrm{d}x\\
&=(-1)^{m-n}2^n n!\int\limits_{-\infty}^{+\infty}\frac{\mathrm{d}^{m-n}}{\mathrm{d}x^{m-n}}\mathrm{e}^{-x^2}\mathrm{d}x
\end{aligned} \tag{7.1.1025}$$

So we get (we use the Gauss integral as proved in the section Statistics page 695):

$$\int\limits_{-\infty}^{+\infty}H_n(x)H_m(x)\,\mathrm{e}^{-x^2}\,\mathrm{d}x=\begin{cases}\text{if } m>n: & 0\\ \text{if } m=n: & n!2^n\displaystyle\int\limits_{-\infty}^{+\infty}\mathrm{e}^{-x^2}\mathrm{d}x=n!2^n\sqrt{\pi}\end{cases} \tag{7.1.1026}$$

Finally, using Kronecker symbol (see section Tensor Calculus page 2044):

$$\boxed{\int\limits_{-\infty}^{+\infty} H_n(x)H_m(x)\,\mathrm{e}^{-x^2}\mathrm{d}x=2^n n!\sqrt{\pi}\delta_{nm}} \tag{7.1.1027}$$

Now let us see a last example useful for our study of the non-rigid rotator in Quantum Chemistry (radial part solution of the hydrogenoid Schrödinger equation):

✍**Example:**

If $L_m(x)$ and $L_n(x)$ are Laguerre's polynomials (see section Calculus page 1404) m,n being positive integers, then:

$$\int\limits_{0}^{+\infty} e^{-x}L_n(x)L_m(x)\mathrm{d}x=\delta_{mn} \tag{7.1.1028}$$

where:

$$\delta_{mn}=\begin{cases}0 & m\neq n\\ 1 & m=n\end{cases} \tag{7.1.1029}$$

The generating function for Laguerre's polynomial gives:

$$\begin{gathered}\sum_{n=0}^{+\infty}L_n(x)t^n=\frac{e^{-\frac{xt}{1-t}}}{1-t}\\ \sum_{m=0}^{+\infty}L_m(x)s^m=\frac{e^{-\frac{xs}{1-s}}}{1-s}\\ \Rightarrow\quad\sum_{n=0}^{+\infty}\sum_{m=0}^{+\infty}L_n(x)L_m(x)t^ns^m=\frac{e^{-x\{t/(1-t)+s/(1-s)\}}}{(1-t)(1-s)}\end{gathered} \tag{7.1.1030}$$

We now multiply both sides of the above by e^{-x} and integrate both sides from 0 to $+\infty$ with respect to x, which gives:

$$\begin{aligned}&\sum_{n=0}^{+\infty}\sum_{m=0}^{+\infty}\left\{\int\limits_{0}^{+\infty}e^{-x}L_n(x)L_m(x)\mathrm{d}x\right\}t^ns^m\\ &=\frac{1}{(1-t)(1-s)}\int\limits_{0}^{+\infty}e^{-x\{1+t/(1-t)+s/(1-s)\}}\mathrm{d}x\\ &=\frac{1}{(1-t)(1-s)}\left|\frac{e^{-x\{1+t/(1-t)+s/(1-s)\}}}{-\left\{1+\frac{t}{1-t}+\frac{s}{1-s}\right\}}\right|_{0}^{+\infty}\\ &=\frac{1}{(1-t)(1-s)}\cdot\frac{1}{1+\frac{t}{1-t}+\frac{s}{1-s}}=\frac{1}{1-st}\\ &=(1-st)^{-1}=1+st+(st)^2+(st)^3+\ldots=\sum_{n=0}^{+\infty}s^nt^n\end{aligned} \tag{7.1.1031}$$

Therefore:

$$\sum_{n=0}^{+\infty}\sum_{m=0}^{+\infty}\left\{\int_0^{+\infty} e^{-x}L_n(x)L_m(x)\mathrm{d}x\right\}t^n s^m=\sum_{n=0}^{+\infty}s^n t^n \tag{7.1.1032}$$

When $m\neq n$, equating coefficients of $t^n s^m$ on both sides of the above relation gives:

$$\int_0^{+\infty} e^{-x}L_n(x)L_m(x)\mathrm{d}x=0 \tag{7.1.1033}$$

When $m=n$, equating coefficients of $t^n s^n$ from both sides of the prior previous relation gives:

$$\int_0^{+\infty} e^{-x}\left[L_n(x)\right]^2\mathrm{d}x=1 \tag{7.1.1034}$$

Combining we get:

$$\int_0^{+\infty} e^{-x}L_n(x)L_m(x)\mathrm{d}x=\delta_{mn} \tag{7.1.1035}$$

where:

$$\delta_{mn}=\begin{cases}0 & \mathrm{m}\neq\mathrm{n}\\ 1 & \mathrm{m}=\mathrm{n}\end{cases} \tag{7.1.1036}$$

Remark

We have already proved in the section of Calculus at page 1400 that the Legendre polynomials (useful for our study of Quantum Chemistry) are orthogonal.

From what we have seen above we deduce that:

$$\langle f|g\rangle=\int_a^b f(x)\cdot\overline{g(x)}\mathrm{d}x \tag{7.1.1037}$$

is in fact generalized by:

$$\boxed{\langle f|g\rangle=\int_a^b f(x)\cdot\overline{g(x)}w(x)\mathrm{d}x} \tag{7.1.1038}$$

where $w(x)$ is the "weight function".

So the engineer, physicist, mathematician must always be careful when he see in a textbook a sentence of the type: «*these functions are orthogonal*». Indeed the author/redactor should instead read: «*these functions are orthogonal with a given weight*».

7.1.6.1 Cauchy-Schwarz inequality for integrals

Let us now provide a detailed proof of what we have mentioned earlier above: the "Cauchy-Schwarz inequality for integrals". As this will be an important result with quite important application in Statistics, Topology and Quantum Physics.

Theorem 7.5. Let f and g be real functions which are continuous on the closed interval $[a,b]$. Then:

$$\boxed{\left(\int_a^b f(t)\,g(t)\,\mathrm{d}t\right)^2 \leq \int_a^b (f(t))^2\,\mathrm{d}t \int_a^b (g(t))^2\,\mathrm{d}t} \tag{7.1.1039}$$

Proof 7.5.1. For the proof we use the following clever trick! We put $\forall x \in \mathbb{R}$:

$$(xf(t)+g(t))^2 \tag{7.1.1040}$$

Hence using relative sizes of definite integrals:

$$0 \leq \int_a^b (xf(t)+g(t))^2\,\mathrm{d}t \tag{7.1.1041}$$

Using the linear combination of integrals property:

$$0 \leq x^2 \int_a^b (f(t))^2\,\mathrm{d}t + 2x \int_a^b f(t)\,g(t)\;\mathrm{d}t + \int_a^b (g(t))^2\,\mathrm{d}t \tag{7.1.1042}$$

Let us put:

$$0 \leq Ax^2+2Bx+C \tag{7.1.1043}$$

where:

$$A=\int_a^b (f(t))^2\,\mathrm{d}t \qquad B=\int_a^b f(t)\,g(t)\,\mathrm{d}t \qquad C=\int_a^b (g(t))^2\,\mathrm{d}t \tag{7.1.1044}$$

The quadratic equation $Ax^2+2Bx+C$ is non-negative for all x. It follows (using the same reasoning as in Cauchy's Inequality) that the discriminant $(2B)^2-4AC$ of this polynomial must be non-positive.

Thus:

$$B^2 \leq AC \tag{7.1.1045}$$

and hence the result!

■ Q.E.D.

That can be interpreted as the functional version of the Cauchy-Schwarz equality for real vectors that we have proven in the section of Vector Calculus (see page 1826):

$$|\vec{x}\circ\vec{y}|\leq\|\vec{x}\|\|\vec{y}\| \tag{7.1.1046}$$

Remember that we have proved the complex version of the latter also (see page 2388):

$$|\langle\vec{x},\vec{y}\rangle|^2\leq\langle\vec{x},\vec{y}\rangle\langle\vec{y},\vec{y}\rangle \tag{7.1.1047}$$

That naturally leads us to build the hermitian Cauchy-Shwarz inequality for integral where $f,g\in\mathbb{C}$:

$$\boxed{\left|\int_a^b \langle f(t),g(t)\rangle|\mathrm{d}t\right|^2\leq\int_a^b |f(t)|^2\,\mathrm{d}t\int_a^b |g(t)|^2\,\mathrm{d}t} \tag{7.1.1048}$$

Also sometimes denoted:

$$\left|\int_a^b f(t)\bar{g}(t)\mathrm{d}t\right|^2\leq\int_a^b |f(t)|^2\,\mathrm{d}t\int_a^b |g(t)|^2\,\mathrm{d}t \tag{7.1.1049}$$

among many other notations with small variations...

7.2. Complex Analysis

BEFORE STARTING this section on the study of differential and integral calculus in the generalized case of complex numbers, I should point out that I used many illustrations inspired by the PDF of E. Hairer (with his permission). This text also contains many sentences and developments taken, homogenized and simplified from the same PDF (at the risk to make some purist readers climbing to the curtains...) according to the notations and educational objectives of the rest of this textbook.

The subject of Complex Analysis is the study of functions $\mathbb{C} \mapsto \mathbb{C}$ and their differentiability (which is different from that in $\mathbb{R}^2$). The "holomorphic functions" (that is to say differentiable in a subset of $\mathbb{C}$) have as we will see it later surprising and elegant properties that can be reused in the situation of the special case of functions in $\mathbb{R}^2$ (remember that $\mathbb{C}$ is a generalization of $\mathbb{R}^2$) that have important applications in advanced physics (we will use the results of this section for our study of quantum physics and also for some applications of fluid mechanics and also for advanced models in financial options pricing).

Before we start let us first explain the interest of Complex Analysis in a simplified way!

We studied in the chapter Algebra a part of the Differential and Integral Calculus with some useful and important theorems in physics and engineering. However, staying in $\mathbb{R}$ or $\mathbb{R}^2$ the list of theorems runs out somehow and we end up finding much relevant tools in practice that allows to simplify the integration calculation that we can sometimes found in industrial applications. So, when we remember that $\mathbb{R} \subset \mathbb{C}$ (thus the set of complex numbers generalizes the set of real numbers) and that we can also build a correspondence $\mathbb{R}^2 \mapsto \mathbb{C}$ as we shall see, then new theorems appear with very interesting results that can be exploit for the integrals in $\mathbb{R}$ or $\mathbb{R}^2$!! It is because of this reason that the engineer needs to know Complex Analysis!

After studying this particular field of mathematics, it is common to say that the shortest path between two truths of the real domain often requires to pass trough the complex domain...

7.2.1 Linear Applications

A good introduction to complex analysis and its representation is to look at first (for educational purposes mainly) the special case of complex linear applications. Let us see this!

Let $U \subset \mathbb{C}$ be a set and $V \subset \mathbb{C}$ another set. A function that associates to each $z \in U$ an $w \in V$ such that:

$$w = f(z) = f(x + \mathrm{i}y) \in V \qquad (7.2.1)$$

is a "complex function":

$$f : U \mapsto V \qquad (7.2.2)$$

What is important is to remember (see section Numbers page 243) that we can identify:

$$z = x + \mathrm{i}y \in \mathbb{C} \mapsto (x,y) \in \mathbb{R}^2 \tag{7.2.3}$$

and:

$$\boxed{w = f(z) = u(x,y) + \mathrm{i}v(x,y) \mapsto (u,v) \in \mathbb{R}^2} \tag{7.2.4}$$

We have thus two functions of two real variables x, y:

$$u(x,y), v(x,y) \tag{7.2.5}$$

which are the coordinates of the point w.

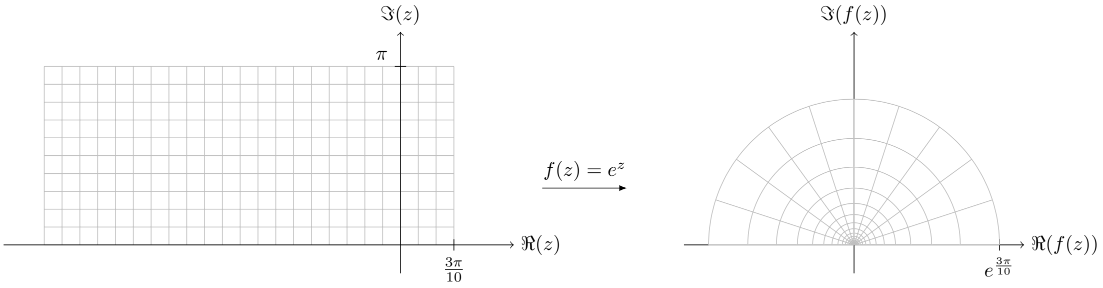

Figure 7.68: **Example of a complex function (conformal mapping)**

Definition (#7.2.288): An application is named "$\mathbb{C}$-linear" if for example a function of the type:

$$w = f(z) = c \cdot z \tag{7.2.6}$$

where c is a fixed complex number and z an arbitrary complex number, satisfies:

$$f(cz_1 + cz_2) = cf(z_1) + cf(z_2) \tag{7.2.7}$$

That is to say that $f(z)$ must me additive and homogeneous or just briefly when this two properties are satisfied we say that $f(z)$ is a "linear map".

We have seen and proved in the section on Numbers during our study of complex numbers, that the multiplication of two complex numbers could be equivalent to an orthogonal rotation followed by a scaling and that this same multiplication could be represented in matrix form! Or the transcription into a matrix form involves as we saw in the section on Linear Algebra automatically the property of linearity!

So the reader can easily check that a matrix of rotation/scaling is an example of an $\mathbb{C}$-linear application (on request we can detail) that we will now write:

$$\begin{pmatrix} u \\ v \end{pmatrix} = \begin{bmatrix} a & -b \\ b & a \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = s \cdot \begin{bmatrix} \cos(\alpha) & -\sin(\alpha) \\ \sin(\alpha) & \cos(\alpha) \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \tag{7.2.8}$$

Which can be typically represented as follows (we can clearly see a rotation and a scaling which conserve the angles and proportions):

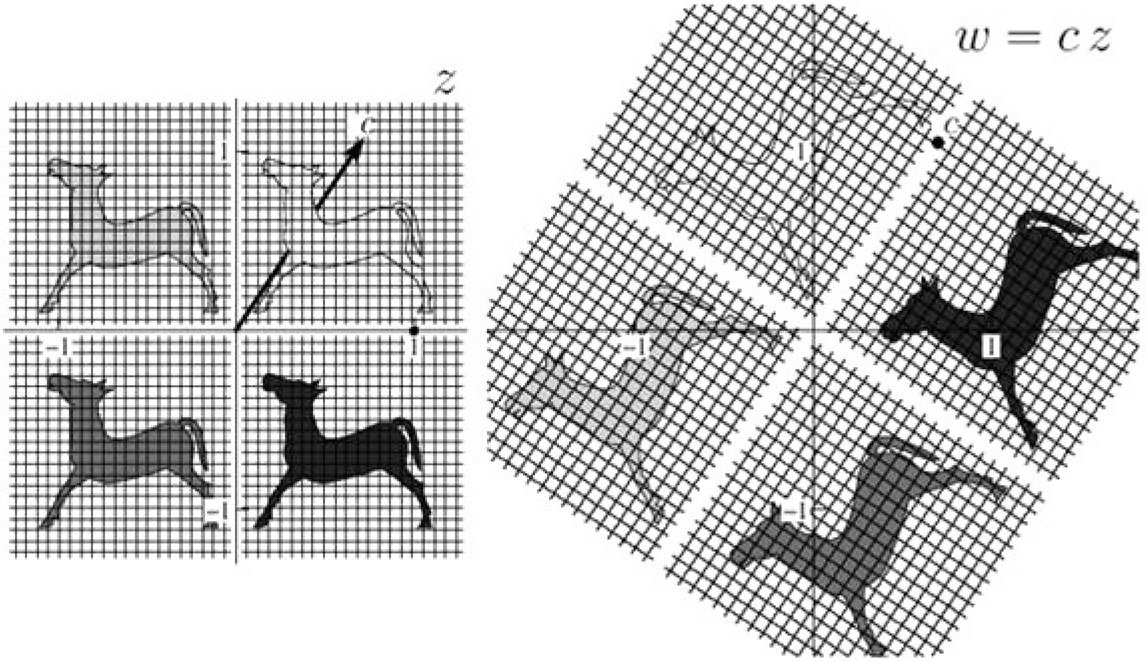

Figure 7.69: $\mathbb{C}$-linear application example

It is the fact that the proportions and the angles are kept that makes a complex function $\mathbb{C}$-linear. Otherwise, we would say that the function is $\mathbb{R}$-linear.

So a matrix equation is $\mathbb{C}$-linear if and only if it is of the form:

$$A = \begin{bmatrix} a & -b \\ b & a \end{bmatrix} \tag{7.2.9}$$

Let us see some examples of quite remarkable $\mathbb{C}$ non-linear functions.

✍**Examples:**

E1. Consider the function:

$$f(z) = z^2 \tag{7.2.10}$$

In real coordinates this gives:

$$f(z) = u + \mathrm{i}v = (x + \mathrm{i}y)^2 = x^2 - y^2 + 2\mathrm{i}xy \Rightarrow \begin{cases} x_1 & = \dfrac{c_1 - b_1 x_2}{a_1} \\ x_2 & = \dfrac{c_2 - a_2 x_1}{b_2} \end{cases} \tag{7.2.11}$$

So let's look what this function do with the points of the complex plane which are coincident with the vertical lines of this same plane (which takes us to write $x = a$). Then we have:

$$u = a^2 - y^2 \qquad v = 2ay \tag{7.2.12}$$

and eliminating y, we find the equation of a parabola or rather a family of parabolas (for several values of b) which are open to the left of the pictured complex plane.

Here is a picture representation of the complex plane on which we have drawn a cat head:

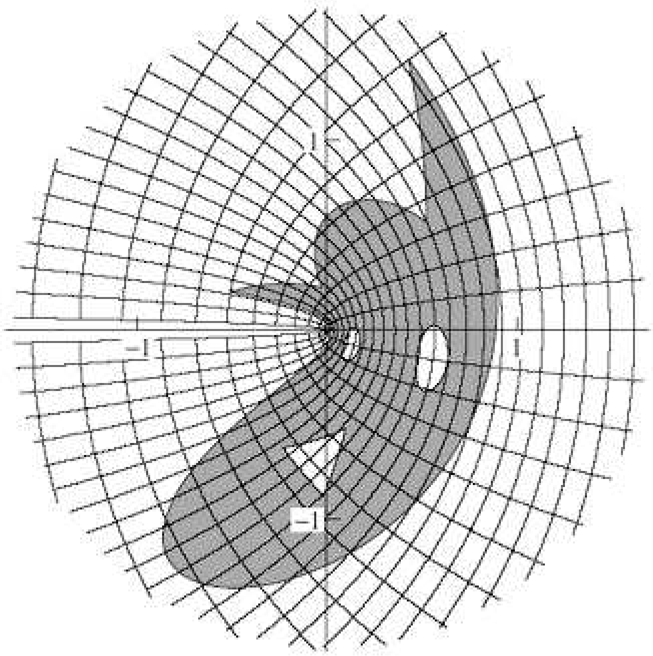

Figure 7.70: **Complex representation of the image of the example function**

and if we look at the corresponding pre-image complex plane then we have two heads of cats that appear:

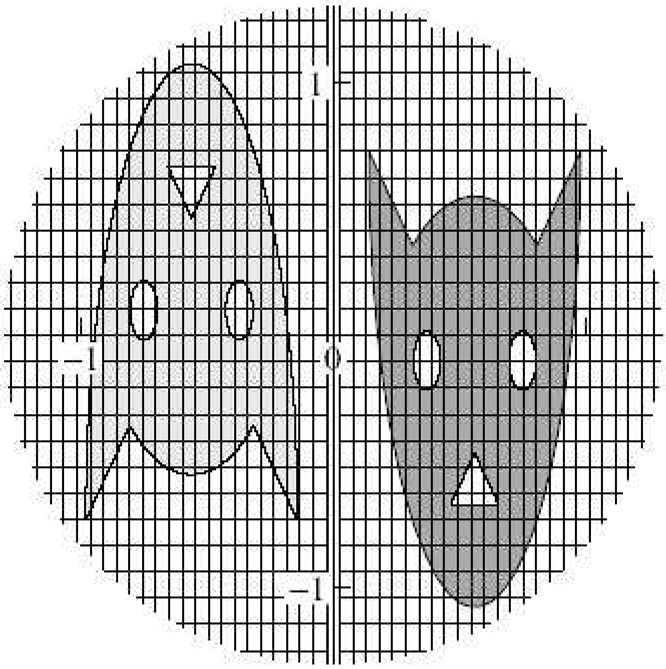

Figure 7.71: **Pre-image representation of the example function**

The appearance of these two heads of cats is that this function has 2 possible pre-images for each image point (so it is a surjective function - see section Set Theory page 406).

Here is a nice Maple™ 17.00 script by Carl Ebehart to check this (shame that this can not be done in an easier way in Maple™):

```
> complextools[gridimage] := proc(p)
local llhc, width, height, xres, yres, clrs, V, H,
i,j,k,l,pz,x,y,z,f,g,xtcs,ytcs,opts,margs;
llhc := [-1, -1];
width := 2;height := 2;
xres := .25;yres := .25;
xtcs := 1; ytcs := 1;
clrs := [red, black];
opts := NULL;
opts := op(select(type,[args],‘=‘));
margs:= remove(type, [args] ,‘=‘) ;
if nops(margs) >1 and margs[2] <> “ then llhc := margs[2] fi:
if nops(margs) >2 and margs[3] <> “ then width := margs[3] fi:
if nops(margs) >3 and margs[4] <> “ then height := margs[4] fi:
if nops(margs) >4 and margs[5] <> “ then xres := margs[5] fi:
if nops(margs) >5 and margs[6] <> “ then yres := margs[6] fi:
if nops(margs) >6 and margs[7] <> “ then xtcs := margs[7] fi:
if nops(margs) >7 and margs[8] <> “ then ytcs := margs[8] fi:      if
nops(margs) >8 and margs[9] <> “ then clrs := margs[9] fi:
z:= x + I*y;
pz := evalc(p(z));
f := unapply(evalc( Re(pz)),x,y); g := unapply(evalc(Im(pz)),x,y);
V:= plot( [ seq([seq(op([[f(llhc[1] + i*xres
,llhc[2]+(j-1)*yres/ytcs),g(llhc[1] + i*xres
,llhc[2]+(j-1)*yres/ytcs)], [f(llhc[1] + i*xres , llhc[2]
+j*yres/ytcs),g(llhc[1] + i*xres , llhc[2] +j*yres/ytcs)]]),
j=1..ytcs*height/yres)], i = 0 ..  width/xres) ],color=clrs[1]);
H := plot( [ seq([seq(op([[f(llhc[1]+(j-1)*xres/xtcs,llhc[2] +
i*yres), g(llhc[1]+(j-1)*xres/xtcs,llhc[2] + i*yres)], [f(llhc[1]
+j*xres/xtcs, llhc[2] + i*yres), g(llhc[1] +j*xres/xtcs, llhc[2]
+ i*yres)]]), j=1..xtcs*width/xres)], i = 0 ..  height/yres)
],color=clrs[2]);
plots[display]([V,H],scaling=constrained,opts); end:
with(complextools);

>plots[display]([seq(plots[display]([gridimage(z->z),
gridimage(z->z^2)]),i=10)],insequence=true);
```

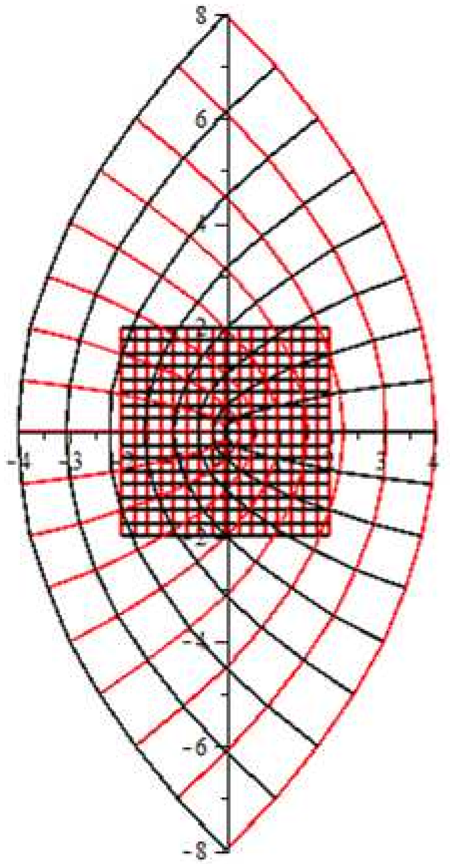

Figure 7.72: **Practical Maple™ 17.00 example of simple C-linear application**

E2. Another interesting feature is the "Cayley transformation" used in some areas of physics and defined as:

$$f(z)=\frac{z+1}{z-1} \tag{7.2.13}$$

having as domain definition: $\mathbb{C}/\{1\}$.

We notice that this is an involutive function since:

$$f(f(z))=f\left(\frac{z+1}{z-1}\right)=\frac{\dfrac{z+1}{z-1}+1}{\dfrac{z+1}{z-1}-1}=\frac{\dfrac{z+1+(z-1)}{z-1}}{\dfrac{z+1-(z-1)}{z-1}}=\frac{z+1+(z-1)}{z+1-(z-1)}=\frac{2z}{2}=z \tag{7.2.14}$$

and as we have proved in the section of Proof Theory (see page 181) that any involution function is both injective and surjective, then the Cayley transform is a bijective function.

This function transforms the imaginary axis $\mathrm{i}y$ in unit circle (and vice versa as it is involutive). Let us see that:

$$\begin{aligned}f(z)=f(\mathrm{i}y)=\frac{\mathrm{i}y+1}{\mathrm{i}y-1}=\frac{\mathrm{i}y+1}{\mathrm{i}y-1}\frac{-\mathrm{i}y-1}{-\mathrm{i}y-1}=\frac{y^2-\mathrm{i}y-\mathrm{i}y-1}{y^2-\mathrm{i}y+\mathrm{i}y+1}=\frac{y^2-2\mathrm{i}y-1}{1+y^2}\\=\frac{y^2-1}{1+y^2}-\mathrm{i}\frac{2y}{1+y^2}=u+\mathrm{i}v\end{aligned} \tag{7.2.15}$$

where:

$$u=\frac{y^2-1}{1+y^2} \qquad v=-\frac{2y}{1+y^2} \tag{7.2.16}$$

satisfies:

$$u^2+v^2=\frac{(y^2-1)^2+(-2y)^2}{(1+y^2)^2}=\frac{(y^4-2y^2+1)+(4y^2)}{1+2y^2+y^4}=1 \tag{7.2.17}$$

That is to say:

$$u^2+v^2=1 \tag{7.2.18}$$

This is the equation of a circle as proven in the section of Analytical Geometric.

E3. As another example of function, consider the "Joukovski transformation" defined by:

$$f(z)=\frac{1}{z}\left(z+\frac{1}{z}\right) \tag{7.2.19}$$

If the definition domain is built in polar coordinates look at how a circle or ellipse transforms with this function:

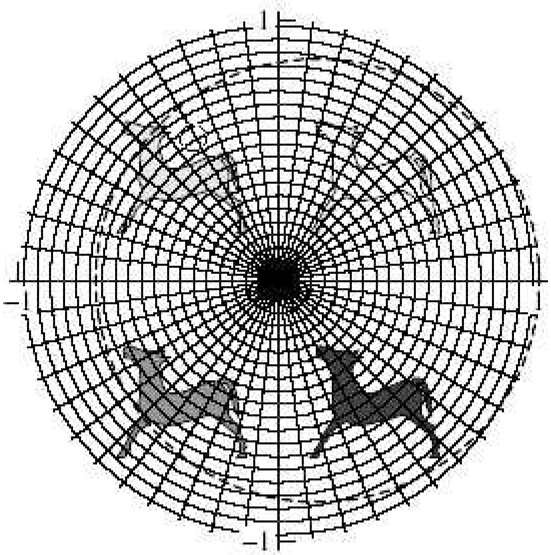

Figure 7.73: Transformation into polar coordinates of an ellipse with the example function

Then the image plane will be:

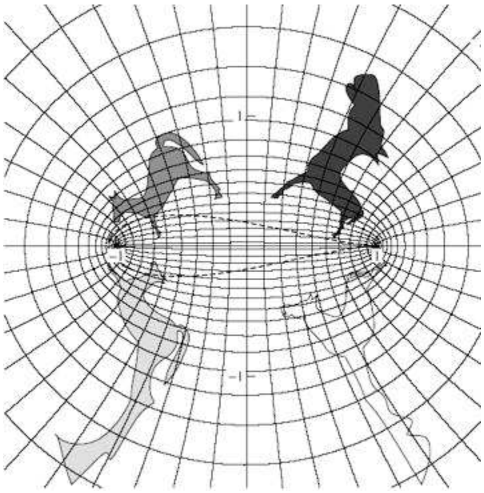

Figure 7.74: **Result of the Joukovski transformation in polar coordinates**

It thus transforms the circles respectively centered at 0 and the rays passing through 0 into a family of cofocal ellipses and hyperbolas. To prove this fact, we use the complex polar coordinates (Euler formula) seen in the section on Numbers (see page 251):

$$z=r(\cos(\varphi)+\mathrm{i}\sin(\phi)) \tag{7.2.20}$$

and:

$$\begin{aligned}z^{-1}&=\frac{1}{r(\cos(\varphi)+\mathrm{i}\sin(\phi))}=r^{-1}\frac{1}{\cos(\varphi)+\mathrm{i}\sin(\phi)}\frac{\cos(\varphi)-\mathrm{i}\sin(\phi)}{\cos(\varphi)-\mathrm{i}\sin(\phi)}\\&=r^{-1}\frac{\cos(\varphi)-\mathrm{i}\sin(\phi)}{\cos^2(\varphi)+\sin^2(\phi)}=r^{-1}(\cos(\varphi)-\mathrm{i}\sin(\phi))\end{aligned} \tag{7.2.21}$$

Then we have:

$$\begin{aligned}f(z)&=\frac{1}{2}\left(r(\cos(\varphi)+\mathrm{i}\sin(\phi))+\frac{1}{r}(\cos(\varphi)-\mathrm{i}\sin(\phi))\right)\\&=\left(\frac{r}{2}+\frac{1}{2r}\right)\cos(\varphi)+\mathrm{i}\left(\frac{r}{2}-\frac{1}{2r}\right)\sin(\phi)\end{aligned} \tag{7.2.22}$$

therefore:

$$u=\left(\frac{r}{2}+\frac{1}{2r}\right)\cos(\varphi)\qquad v=\left(\frac{r}{2}-\frac{1}{2r}\right)\sin(\phi) \tag{7.2.23}$$

and we immediately see that (see section Trigonometry page 2519):

$$\cos^2(\varphi)+\sin^2(\phi)=\frac{u^2}{\left(\dfrac{r}{2}+\dfrac{1}{2r}\right)^2}+\frac{v^2}{\left(\dfrac{r}{2}-\dfrac{1}{2r}\right)^2}=1 \tag{7.2.24}$$

has the form of the equation of an ellipse (see section Analytical Geometry page 2768) and we also have:

$$\begin{aligned}\frac{u^2}{\cos^2(\varphi)}-\frac{v^2}{\sin^2(\phi)}&=\left(\frac{r}{2}+\frac{1}{2r}\right)^2-\left(\frac{r}{2}-\frac{1}{2r}\right)^2\\&=\left(\frac{r^2}{4}+2\frac{r}{2}\frac{1}{2r}+\frac{1}{4r^2}\right)-\left(\frac{r^2}{4}-2\frac{r}{2}\frac{1}{2r}+\frac{1}{4r^2}\right)\\&=2\frac{r}{2}\frac{1}{2r}+2\frac{r}{2}\frac{1}{2r}=\frac{1}{2}+\frac{1}{2}=1\end{aligned}\tag{7.2.25}$$

which is the equation of a hyperbola (see section Analytical Geometry page 2768).

This function is useful in case we cleverly place a circle through the point $z=1$ (as in the case of the first figure) the plan represented in polar coordinates with a dotted line might looks like an airplane wing. This allowed a time ago in aerodynamics (but the technique is obsolete today) to transpose the study of a vector field of an airplane wing profile to the study of a circle profile and to do after the Joukovski transformation.

Indeed, let us see a part of this still with Maple™ 4.00:

```
> assume(x,real,y,real);
> z:=x+I*y;
> F:=1/2*(z+1/z);
> u:=Re(F);
> u:=evalc(u);
> v:=Im(F); > v:=evalc(v);
> with(plots):with(plottools):
> p1:=disk([0,0],1,color=black):
> p2:=implicitplot(seq(v=b8,b=-10..10),x=-4..4,y=-2..2,color=black):
> display([p2,p1],scaling=constrained);
```

We thus get:

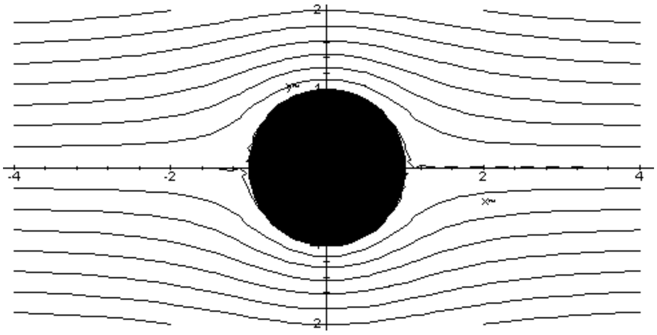

Figure 7.75: **Important application example of the Joukovski function**

Let us see a last example that shows an electric dipole with its electric field and potential lines (see section Electrostatics page 3980) can bee seen as the emergence of the $\mathbb{C}$-linear function $1/z$:

✍**Examples:**

E4. Always with Maple™ 4.00b we write:

```
>assume(x,real,y,real);
> z:=x+I*y;
> F:=1/z;
> u:=Re(F);u:=evalc(u);
> v:=Im(F);v:=evalc(v);
> with(plots):
> p1:=implicitplot(seq(u=a,a=-5..5),x=-1..1,y=-1..1,numpoints=1000):
> p2:=implicitplot(seq(v=b,b=-5..5),x=-1..1,y=-1..1,numpoints=1000,
color=green):
> display([p1,p2],scaling=constrained);
```

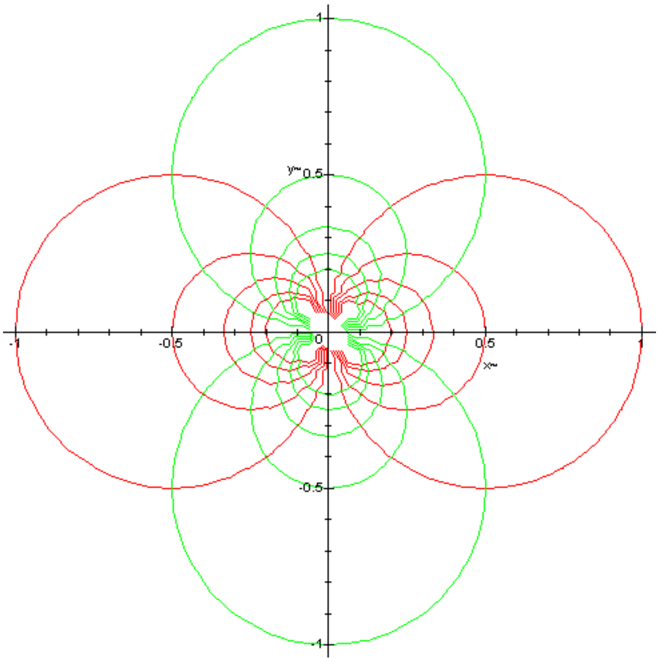

Figure 7.76: **Another important application of a complex function**

7.2.2 Holomorphic Functions

The definition of the derivative with respect to a complex variable is naturally formally identical to the derivative with respect to a real variable.

We then have, if the function $f(z)$ is differentiable in z_0:

$$\frac{\mathrm{d}f_h}{\mathrm{d}z}=\lim_{z\to z_0}\frac{f(z)-f(z_0)}{z-z_0}=\lim_{h\to 0}\frac{f(z_0+h)-f(z_0)}{(z_0+h)-z_0}=\lim_{h\to 0}\frac{f(z_0+h)-f(z_0)}{h}=f'(z) \quad (7.2.26)$$

and we say (abusively in this textbook) that function is "holomorphic" (while in $\mathbb{R}$ we say "differentiable") or "analytical" in its domain or in a subset of it if it is differentiable at any point.

In other words a holomorphic functions is a complex-valued function of one or more complex variables that is complex differentiable in a neighbourhood of every point in its domain. The existence of a complex derivative in a neighbourhood is a very strong condition, for it implies that any holomorphic function is actually infinitely differentiable and equal to its own Taylor series.

Remarks

R1. A complex function is derived like a real function, we just have to put z as being x... at the condition of what we will see in what follows is respected!

R2. In fact if the function is holomorphic in a subset of the complex plane, we will see a little further below in our study of the convergence of power series that this is than always an open subset.

Equivalently, we say that the function f is $\mathbb{C}$-differentiable if the following limit exists in $\mathbb{C}$:

$$\lim_{h\rightarrow 0}\frac{f(z_0+h)-f(z_0)}{h}=f'(z_0) \tag{7.2.27}$$

Let us now present and prove a central theorem for complex analysis named "Cauchy-Riemann theorem"!

If the function:

$$f(z)=f(x,y)=f(x+\mathrm{i}y)=u(x,y)+\mathrm{i}v(x,y) \tag{7.2.28}$$

is $\mathbb{C}$-differentiable on $z_0=x_0+\mathrm{i}y_0$, then we have:

$$\boxed{\frac{\partial u}{\partial x}=\frac{\partial v}{\partial y} \qquad \frac{\partial v}{\partial x}=-\frac{\partial u}{\partial y}} \tag{7.2.29}$$

which is somewhat the equivalent to the Schwarz theorem (limited to $\mathbb{R}$) proved in the section of Differential and Integral Calculus (see page 1469). The above two relations are named "Cauchy conditions". So these are the two conditions that must verify a complex function to be differentiable on z_0. Thus, it is possible to use these relations to examine the points where the function is not analytic.

Theorem 7.6. If these conditions are satisfied (what we will prove right below!), then we deduce that u and v must both be harmonic functions of x and y.

Proof 7.6.1. As:

$$\lim_{h\rightarrow 0}\frac{f(z_0+h)-f(z_0)}{h}=f'(z_0) \tag{7.2.30}$$

by choosing:

$$z=z_0+x \tag{7.2.31}$$

with $x \in \mathbb{R}$, we get:

$$f'(z_0)=\lim_{z\rightarrow z_0}\frac{f(x_0+x,y_0)-f(x_0,y_0)}{z_0+x-z_0}=\lim_{z\rightarrow z_0}\frac{f(x_0+x,y_0)-f(x_0,y_0)}{x} \tag{7.2.32}$$

and as x approaches a small value $\mathrm{d}x$, we have (see section Differential and Integral Calculus page 1450):

$$\begin{aligned}f'(z_0)&=\lim_{\mathrm{d}x\rightarrow 0}\frac{f(x_0+\mathrm{d}x,y_0)-f(x_0,y_0)}{\mathrm{d}x}=\frac{\partial f(z_0)}{\partial x}=\frac{\partial(u(x_0,y_0)+\mathrm{i}v(x_0,y_0))}{\partial x}\\&=\frac{\partial}{\partial x}u(x_0,y_0)+\mathrm{i}\frac{\partial}{\partial x}v(x_0,y_0)\end{aligned} \tag{7.2.33}$$

by choosing:

$$z=z_0+\mathrm{i}y \tag{7.2.34}$$

with $y \in \mathrm{R}$, we get:

$$f'(z_0)=\lim_{z\rightarrow z_0}\frac{f(x_0,y_0+\mathrm{i}y)-f(x_0,y_0)}{z_0+\mathrm{i}y-z_0}=\lim_{z\rightarrow z_0}\frac{f(x_0,y_0+\mathrm{i}y)-f(x_0,y_0)}{\mathrm{i}y} \tag{7.2.35}$$

and when y tends to a small value we have (see section Differential and Integral Calculus page 1450):

$$\begin{aligned}f'(z_0)&=\lim_{\mathrm{d}y\rightarrow 0}\frac{f(x_0,y_0+\mathrm{i}\mathrm{d}y)-f(x_0,y_0)}{\mathrm{i}\mathrm{d}y}=\frac{1}{\mathrm{i}}\frac{\partial f(z_0)}{\partial y}=-\frac{\partial f(z_0)}{\partial y}\\&=-\mathrm{i}\frac{\partial(u(x_0,y_0)+\mathrm{i}v(x_0,y_0))}{\partial y}=-\mathrm{i}\left(\frac{\partial u(x_0,y_0)}{\partial y}+\mathrm{i}\frac{\partial v(x_0,y_0)}{\partial y}\right)\\&=\frac{\partial}{\partial y}v(x_0,y_0)-\mathrm{i}\frac{\partial}{\partial y}u(x_0,y_0)\end{aligned} \tag{7.2.36}$$

So now we have:

$$\begin{aligned}\left(\frac{\partial f}{\partial x}\right)_y&=\frac{\partial f}{\partial y}=\frac{\partial}{\partial x}u(x_0,y_0)+\mathrm{i}\frac{\partial}{\partial x}v(x_0,y_0)\\\left(\frac{\partial f}{\partial y}\right)_x&=\frac{\partial f}{\partial x}=\frac{\partial}{\partial y}v(x_0,y_0)-\mathrm{i}\frac{\partial}{\partial y}u(x_0,y_0)\end{aligned} \tag{7.2.37}$$

But remember we proved in the section of Integral and Differential Calculus the following theorem (see page 1469):

$$\frac{\partial^2 f}{\partial x\partial y}=\frac{\partial^2 f}{\partial y\partial x} \tag{7.2.38}$$

Hence:

$$\begin{aligned}\frac{\partial^2 f}{\partial y\partial x}&=\frac{\partial}{\partial y}\left(\frac{\partial}{\partial x}u(x_0,y_0)+\mathrm{i}\frac{\partial}{\partial x}v(x_0,y_0)\right)\\\frac{\partial^2 f}{\partial x\partial y}&=\frac{\partial}{\partial x}\left(\frac{\partial}{\partial y}v(x_0,y_0)-\mathrm{i}\frac{\partial}{\partial y}u(x_0,y_0)\right)\end{aligned} \tag{7.2.39}$$

Therefore using directly Schwartz theorem:

$$\frac{\partial}{\partial y}\left(\frac{\partial}{\partial x}u(x_0,y_0)+\mathrm{i}\frac{\partial}{\partial x}v(x_0,y_0)\right)=\frac{\partial}{\partial x}\left(\frac{\partial}{\partial y}v(x_0,y_0)-\mathrm{i}\frac{\partial}{\partial y}u(x_0,y_0)\right) \qquad (7.2.40)$$

Which can be written:

$$\frac{\partial}{\partial y}\left(\frac{\partial}{\partial x}u(x_0,y_0)+\mathrm{i}\frac{\partial}{\partial x}v(x_0,y_0)\right)-\frac{\partial}{\partial x}\left(\frac{\partial}{\partial y}v(x_0,y_0)-\mathrm{i}\frac{\partial}{\partial y}u(x_0,y_0)\right)=0 \qquad (7.2.41)$$

A trivial solution is obviously to have:

$$\begin{aligned}\frac{\partial}{\partial x}u(x_0,y_0)+\mathrm{i}\frac{\partial}{\partial x}v(x_0,y_0)=0)\\ \frac{\partial}{\partial y}v(x_0,y_0)-\mathrm{i}\frac{\partial}{\partial y}u(x_0,y_0)=0\end{aligned} \qquad (7.2.42)$$

Therefore we are authorized to write:

$$\frac{\partial}{\partial x}u(x_0,y_0)+\mathrm{i}\frac{\partial}{\partial x}v(x_0,y_0)=\frac{\partial}{\partial y}v(x_0,y_0)-\mathrm{i}\frac{\partial}{\partial y}u(x_0,y_0)=0 \qquad (7.2.43)$$

By identifying real and imaginary parts, we finish the proof!

■ Q.E.D.

So for f to be differentiable in the complex domain $\mathbb{C}$ (holomorphic) at a point, it is sufficient that it be differentiable as a function of two real variables ($\mathbb{R}^2$-differentiable on (x_0,y_0)) and that its partial first derivatives at this point satisfy the Cauchy-Riemann equations.

But, for it to be $\mathbb{C}$-differentiable, Cauchy-Riemann's equations must valid at all points of the complex plane (we sometimes speaks about "complete functions") and not only in a subdomain thereof! Otherwise, it contains therefore "singularities" and we then speak of "meromorphic function" (which is therefore a holomorphic function excepted on singularities points).

The Gamma function studied in the section of Differential and Integral Calculus (see page 1574) and plotted with Maple™ 4.00b (code provided!) is such a well-known meromorphic function.

Remark

Geometrically, we will prove later that a holomorphic function has a possible interpretation in the sense that it is a conformal transformation (angles conservation).

Notice therefore that if $f(z)$ is $\mathbb{C}$-differentiable it can be developed as Taylor series (see section Sequences and Series page 1696):

$$f(z)=\sum_{i=0}^{+\infty}\frac{1}{n!}\frac{\mathrm{d}^n f(z_0)}{\mathrm{d}z^n}(z-z_0)^n \qquad (7.2.44)$$

Note an important thing too. If we rewrite:

$$\frac{\partial u}{\partial x}=\frac{\partial v}{\partial y} \qquad \frac{\partial v}{\partial x}=-\frac{\partial u}{\partial y} \qquad (7.2.45)$$

as following:

$$\begin{aligned}\frac{\partial u}{\partial x}-\frac{\partial v}{\partial y}=0\\ \frac{\partial v}{\partial x}+\frac{\partial u}{\partial y}=0\end{aligned} \tag{7.2.46}$$

Then we say that f is "irrotational" (see section Vector Calculus page 1889) since the first relation can be seen as:

$$\frac{\partial u}{\partial x}-\frac{\partial v}{\partial y}=\text{rot}(\vec{f})_z=0 \tag{7.2.47}$$

which is an important analogy! Finally, the second equation:

$$\frac{\partial v}{\partial x}+\frac{\partial u}{\partial y}=0 \tag{7.2.48}$$

also let us say by analogy (but it stops at a simple analogy!) that the bivariate function f is non-divergent (see section Vector Calculus page 1879) what is good mnemonic way to remember this equation.

Let's also show something else in evidence. If we take the two Cauchy-Riemann equations:

$$\begin{aligned}\frac{\partial u}{\partial x}=\frac{\partial v}{\partial y}\\ \frac{\partial u}{\partial y}=-\frac{\partial v}{\partial x}\end{aligned} \tag{7.2.49}$$

and that we derivate them once again, we get:

$$\begin{aligned}\frac{\partial^2 u}{\partial x^2}=\frac{\partial^2 v}{\partial x\partial y}\\ \frac{\partial^2 u}{\partial y^2}=-\frac{\partial^2 v}{\partial y\partial x}\end{aligned} \tag{7.2.50}$$

and that we sum these two relations, we get then:

$$\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}=0 \tag{7.2.51}$$

It is the same with v. Then we have:

$$\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}=0 \qquad \frac{\partial^2 v}{\partial x^2}+\frac{\partial^2 v}{\partial y^2}=0 \tag{7.2.52}$$

And we know very well this form of equations (Maxwell-Poisson equation in the section of Electrodynamics and Newton-Poisson equation in the section of Astronomy...). This is a wave equation also named "Laplace equation" (nothing to do with that of the same name seen in our study of the hydrostatic!) and given by the scalar Laplacian (see section Vector Calculus page 1899):

$$\boxed{\Delta\cdot u=\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}=0 \qquad \Delta\cdot v=\frac{\partial^2 v}{\partial x^2}+\frac{\partial^2 v}{\partial y^2}=0} \tag{7.2.53}$$

Then it is traditional to say that u is harmonic and of course we can get the same result with v! Well obviously ... we knew it, since we have already studied in the section Numbers that the real and imaginary parts of a complex number could be put in trigonometric form.

Thanks to this discovery, Riemann opened the application of holomorphic functions in many problems of physics, since these equations are satisfied by the gravitational potential (Newton-Poisson equation in the section of Astronomy page 5267) by electric and magnetic fields (Maxwell-Poisson equation in the section of Electrodynamics page 4099) by heat balance (no examples yet in this textbook) and by movements without rotational of certain fluids (no examples either in this textbook yet).

✍Example:

The potential of a dipole can be described by the following holomorphic function:

$$f(z)=\frac{1}{z+1}+\frac{1}{z-1} \tag{7.2.54}$$

The figure below:

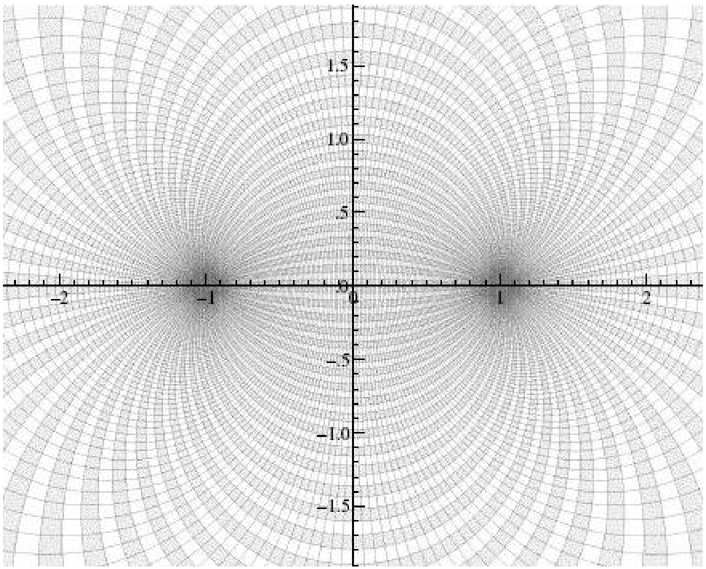

Figure 7.77: **Plane representation of a well known holomorphic function...**

shows level-curves (iso-curves) of the given harmonic functions $u(x,y)$ and $v(x,y)$ as real and complex parts of the function $f(z)$ of this example.

7.2.2.1 Orthogonality of real and imaginary iso-curves

We will now prove a friendly property that have the functions that satisfy the Cauchy conditions (i.e. that are analytic functions!). Indeed, remember that we have already seen above the function:

$$f(z)=z^2 \tag{7.2.55}$$

which gave the following diagram:

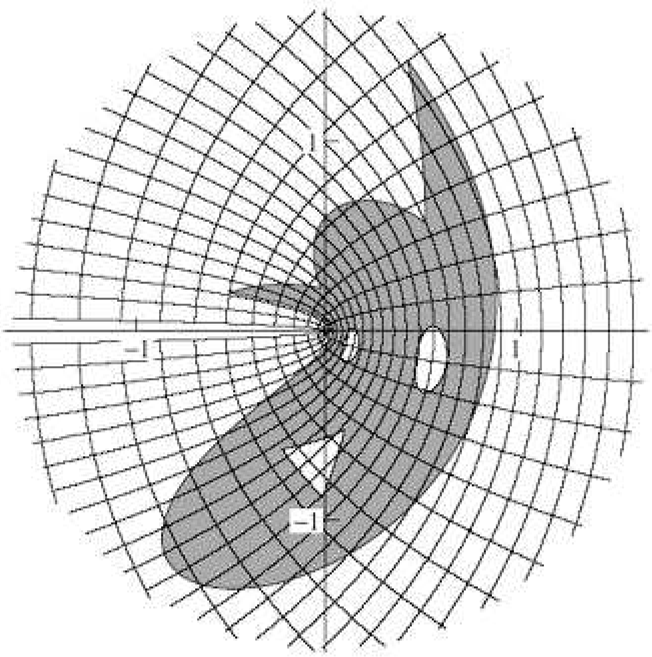

Figure 7.78: **Reminder of plane representation of a complex function seen earlier**

Theorem 7.7. The functions satisfying the Cauchy conditions have the simple following geometrical property: the lines whose real part of the function is constant $\mathcal{R}(f(z))=c^{te}$ and the lines whose imaginary part is constant $\mathcal{I}(f(z))=c^{te}$ are orthogonal to each other (think to the trigonometric form of complex numbers it helps to better visualize!).

In other words, the analytical complex functions are transformation functions of an area of the plane into a new plane where the angles are preserved. Then we say that the function is a "complete transformation".

Proof 7.7.1. For the proof remember that we have proved in the section of Vector Calculus that gradient of a function f of $\mathbb{R}^2$ is given by:

$$\vec{\nabla}(f)=\left(\frac{\partial f}{\partial x},\frac{\partial f}{\partial y}\right) \tag{7.2.56}$$

and as part of our study of isolines in the section of Differential Geometry that the tangent vector to isolines of the function f will always be parallel to the vector of the plane:

$$\vec{t}=\left(\frac{\partial f}{\partial y},-\frac{\partial f}{\partial x}\right) \tag{7.2.57}$$

and that the latter two vectors are perpendicular, such that:

$$\vec{\nabla}(f)\circ\vec{t}=0 \tag{7.2.58}$$

Now assimilate the tangent (parallel) vector $\vec{t}_u$ to the real isolines:

$$\Re(f(z))=u(x,y)=c^{te} \tag{7.2.59}$$

with:

$$\vec{t}_u=\left(\frac{\partial u}{\partial y},-\frac{\partial u}{\partial x}\right) \tag{7.2.60}$$

and the normal vector to the imaginary isolines:

$$\Im(f(z))=v(x,y)=c^{te} \tag{7.2.61}$$

with the gradient v of components:

$$\vec{\nabla}(v)=\left(\frac{\partial v}{\partial x},\frac{\partial v}{\partial y}\right) \tag{7.2.62}$$

Using the Cauchy conditions proved above, we have for this last relation:

$$\vec{\nabla}(v)=\left(\frac{\partial v}{\partial x},\frac{\partial v}{\partial y}\right)=\left(-\frac{\partial u}{\partial y},\frac{\partial u}{\partial x}\right) \tag{7.2.63}$$

By comparing:

$$\vec{t}_u=\left(\frac{\partial u}{\partial y},-\frac{\partial u}{\partial x}\right)\quad\text{and}\quad\vec{\nabla}(v)=\left(-\frac{\partial u}{\partial y},\frac{\partial u}{\partial x}\right) \tag{7.2.64}$$

we therefore see that $\vec{t}_u$ and $\vec{\nabla}(v)$ are parallel (collinear). And since $\vec{t}_u$ is colinear the real isolines and that $\vec{\nabla}(v)$ is perpendicular to the imaginary isolines we finished our proof.

■ Q.E.D.

The reader may take as an example the function:

$$f(z)=z^2 \tag{7.2.65}$$

mathematically and schematically detailed earlier above! But to change a little bit, consider an example that will accompany us throughout the rest of this section and that is the following holomorphic function:

$$f(z)=\frac{1}{1+z^2} \tag{7.2.66}$$

That gives us with Maple™ 4.00b:

```
 >assume(x,real,y,real);
> z:=1/(1+(x+I*y)^2);
> F:=1/z;
> u:=Re(F);
> u:=evalc(u);
> v:=Im(F);
> v:=evalc(v);
> with(plots):
> p1:=implicitplot(seq(u=a,a=-5..5),x=-5..5,y=-5..5,numpoints=1000):
> p2:=implicitplot(seq(v=b,b=-5..5),x=-5..5,y=-5..5,numpoints=1000,color=green):
> display([p1,p2]);
```

which gives:

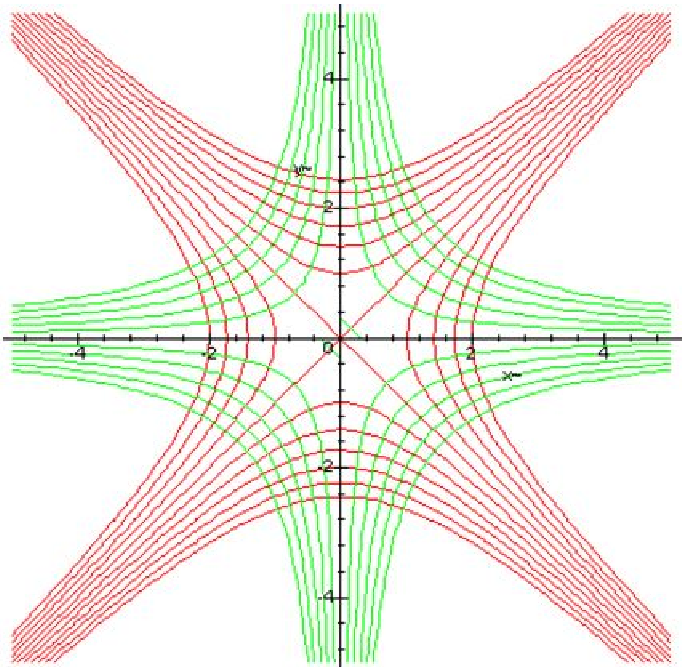

Figure 7.79: **Representation of an important holomorphic function with its isolines**

7.2.3 Complex Logarithm

We need for all functions built into $\mathbb{R}$ found their equivalent in $\mathbb{C}$ while knowing that if we reduce the case of $\mathbb{R}$ to $\mathbb{C}$ we must get back on our feet!

To do this, let us start with the most classical and academic function which is the logarithm and also the only one function for which we will need the complex version in other sections of this textbook. As always we will focus only on the properties that we will need later for practical applications and nothing more!

In the same way that we built the logarithm as being by definition by the inverse function of the natural exponential e^x in the section of Functional Analysis, we first start from:

$$f(z)=e^z \tag{7.2.67}$$

where z is a complex number and we will define the complex logarithm that must be reduced to the natural logarithm if z has no imaginary part!

So by definition the complex logarithm will be:

$$\boxed{w=e^z \Leftrightarrow z=\text{Log}(w)} \tag{7.2.68}$$

and in this entire book, the complex logarithm will be differentiated by the real logarithm by a capital L for the first letter!

Let us write z and w in the Euler form as viewed in the section Numbers:

$$\begin{aligned} w&=x+\mathrm{i}y=r(\cos(\theta)+\mathrm{i}\sin(\theta))=|w|e^{\mathrm{i}\text{arg}(w)}=|w|(\cos(\text{arg}(w))+\sin(\text{arg}(w)))\\ z&=u+\mathrm{i}v \end{aligned} \tag{7.2.69}$$

Then we have:

$$w=e^z \Rightarrow r(\cos(\theta)+\mathrm{i}\sin(\theta))=e^{u+\mathrm{i}v}=e^u e^{\mathrm{i}v}=e^u \tag{7.2.70}$$

By correspondence, we find immediately:

$$r=|w|=e^u \Leftrightarrow u=\ln(r) \quad \text{and} \quad v=\text{arg}(w)=\theta+2\pi k \tag{7.2.71}$$

with $k\in\mathbb{Z}$. Therefore we get:

$$z=u+\mathrm{i}v=\ln(r)+\mathrm{i}\text{arg}(w)=\ln(r)+\mathrm{i}(\theta+2\pi k)=\text{Log}(w) \tag{7.2.72}$$

Therefore:

$$\boxed{z=\text{Log}(w)=\ln(r)+\mathrm{i}(\theta+2\pi k)} \tag{7.2.73}$$

or more explicitly:

$$\boxed{\text{Log}(w)=\ln(|w|)+\mathrm{i}\text{arg}(w)} \tag{7.2.74}$$

So if w has no imaginary part, we fall back on our feet since arg(w) becomes zero.

A big difference is highlighted between the logarithm of the complex and real numbers: the complex numbers logarithms can take several values because of the argument!!

We can also check that:

$$e^{\text{Log}(w)}=e^{\ln|w|+\mathrm{i}\,\text{arg}(w)}=e^{\ln|w|}e^{\mathrm{i}\,\text{arg}(w)}=|w|e^{\mathrm{i}\,\text{arg}(w)}=w \tag{7.2.75}$$

For a function to have an inverse, it must map distinct values to distinct values, i.e., be injective. But the complex exponential function is not injective, because $e^{z+2\pi\mathrm{i}}=e^z$ for any z, since adding $\mathrm{i}\theta$ to w has the effect of rotating e^z counter-clockwise of θ radians. So all the points of the form $z+\mathrm{i}k\theta$ are all mapped to the same number by the exponential function. So the exponential function does not have an inverse function in the standard sense.

There are two solutions to this problem:

1. One is to restrict the domain of the exponential function to a region that does not contain any two numbers differing by an integer multiple of $2\pi\mathrm{i}$: this leads naturally to the definition of "branches" of Log(w), which are certain functions that single out one logarithm of each number in their domains.

2. Another way to resolve the indeterminacy is to view the logarithm as a function whose domain is not a region in the complex plane, but a "Riemann surface" that covers the punctured complex plane in an infinite-to-1 way.

Branches have the advantage that they can be evaluated at complex numbers. On the other hand, the function on the Riemann surface is elegant in that it packages together all branches of $\text{Log}(w)$ and does not require an arbitrary choice as part of its definition.

We can see this with Maple™ 4.00b easily:

```
>plot3d([r*cos(f),r*sin(f),f],r=0..1,f=-2*Pi..2*Pi,axes=boxed,style=patch,
shading=ZHUE);
```

which gives:

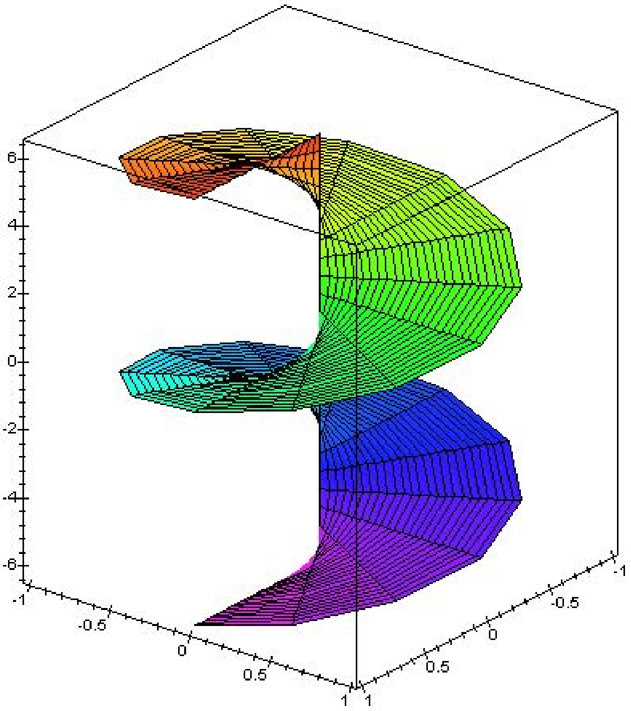

Figure 7.80: **Complex Logarithm plot in Maple™ 4.00b**

Or in high resolution using TikZ:

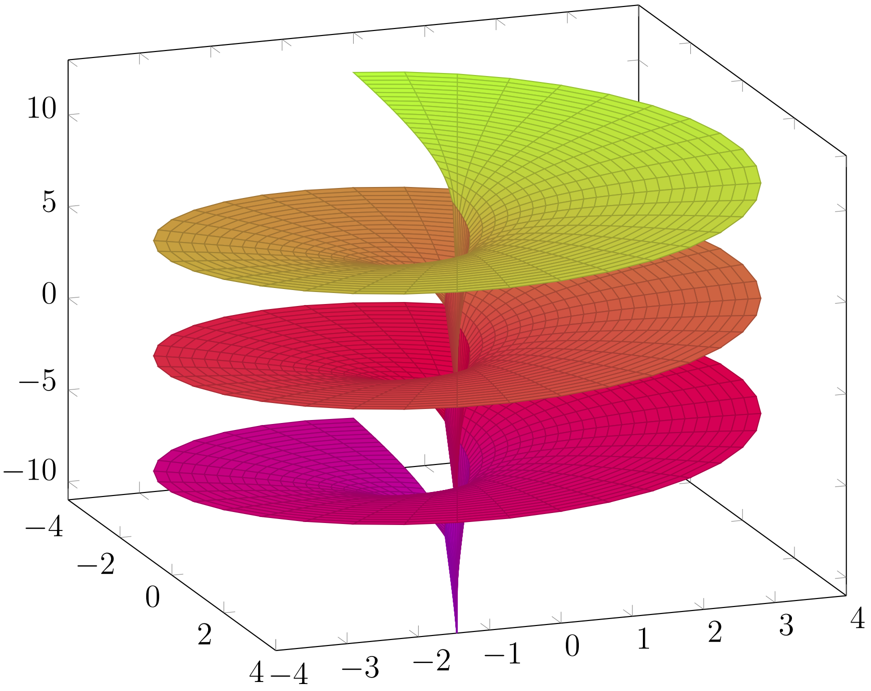

Figure 7.81: **Complex Logarithm with TikZ**

For this reason, one cannot always apply Log to both sides of an identity $e^{z_1}=e^{z_2}$ to deduce $z_1=z_2$. Also, the identity $\text{Log}(z_1z_2)=\text{Log}(z_1)+\text{Log}(z_2)$ can fail: the two sides can differ by an integer multiple of $2\pi\text{i}$.

For each non-zero complex number $w=x+\text{i}y$, the principal value $\text{Log}(w)$ is the logarithm whose imaginary part lies in the interval $[-\pi,+\pi]$. The expression $\text{Log}(0)$ is left undefined since there is no complex number z satisfying $e^z=0$.

Then the principal value of the complex logarithm can be defined by (see section Trigonometry page 2503):

$$\boxed{\text{Log}(w)=\ln(|w|)+\text{i}\arg(w)=\ln(\sqrt{x^2+y^2})+\text{i}\arctan2(y,x)} \tag{7.2.76}$$

We see also obviously that the function $\text{Log}(w)$ is discontinuous at each negative real number (we can see it on the figure above), but continuous everywhere else in $\mathbb{C}^*$.

Riemann surfaces can be thought of as deformed versions of the complex plane: locally near every point they look like patches of the complex plane, but the global topology can be quite different. For example, they can look like a sphere or a torus or a couple of sheets glued together.

The main point of Riemann surfaces is that holomorphic functions may be defined between them. Riemann surfaces are nowadays considered the natural setting for studying the global behaviour of these functions, especially multi-valued functions such as the square root and other algebraic functions, or the logarithm.

Basically, a Riemann surface is simply just a surface, as far as the shape is concerned. Any normal surface you can think of (for example, plane, sphere, torus, ...) are all Riemann surfaces. We say it's a "Riemann surface", is due to the context, is that we define the surface using complex functions, and for use in studying complex functions.

7.2.4 Complex Integral Calculus

We have seen just above how to check if a complex function $f(z)$ was differentiable (it must at least respect the Cauchy-Riemann equations) at any point.

Now let us see the opposite case... the integration that is absolutely fascinating in complex plane!

We have obviously taking again the notations of the section of Differential and Integral Calculus:

$$F(z)=\int f(z)\mathrm{d}z \tag{7.2.77}$$

either in explicit form:

$$\begin{aligned}F(z)&=\int f(x+\mathrm{i}y)\mathrm{d}(x+\mathrm{i}y)=\int(u+\mathrm{i}v)(\mathrm{d}x+\mathrm{i}\mathrm{d}y)\\&=\left[\int(u\mathrm{d}x-v\mathrm{d}y)\right]+\mathrm{i}\left[\int(v\mathrm{d}x+u\mathrm{d}y)\right]\\&=\int u\mathrm{d}x-\int v\mathrm{d}y+\mathrm{i}\int v\mathrm{d}x+\mathrm{i}\int u\mathrm{d}y\end{aligned} \tag{7.2.78}$$

Well once this expression established, let us give a little explanation about how to read it:

1. We know that u and v are dependent both in the general case of x and y.
2. We know that u and v represent (see examples at the beginning of this section) closed or open curves and also straight lines when x (or respectively y) is fixed and that the other associated variable varies!

So each term have an integral in the above expression is in fact a line integral on a family of open or closed curves (including a specific case that is straight lines...)!

This integral can be evaluated using the Green's theorem in the plane (see section Vector Calculus page 1890) if we consider the particular case of a closed curvilinear path such as:

$$F(z)=\oint(u\mathrm{d}x-v\mathrm{d}y)+\mathrm{i}\oint(v\mathrm{d}x+u\mathrm{d}y) \tag{7.2.79}$$

Let us first study the real part:

Indeed we proved (it is strongly advised to read again this Green's theorem) in the section of Vector Calculus that:

$$\oint(f_x\mathrm{d}x+f_y\mathrm{d}y)=\int\limits_S\left(\frac{\partial f_y}{\partial x}-\frac{\partial f_x}{\partial y}\right)\mathrm{d}S_z=\int\limits_S\left(\frac{\partial f_y}{\partial x}-\frac{\partial f_x}{\partial y}\right)\mathrm{d}x\mathrm{d}y \tag{7.2.80}$$

What will be written in our situation:

$$\oint(u\mathrm{d}x+(-v)\mathrm{d}y)=\int\limits_S\left(\frac{\partial(-v)}{\partial x}-\frac{\partial u}{\partial y}\right)\mathrm{d}x\mathrm{d}y=-\int\limits_S\left(\frac{\partial v}{\partial x}+\frac{\partial u}{\partial y}\right)\mathrm{d}x\mathrm{d}y \tag{7.2.81}$$

However, if the function is holomorphic and thus satisfies the Cauchy-Riemann equations we get immediately:

$$\oint (u\mathrm{d}x + (-v)\mathrm{d}y) = -\int_S \underbrace{\left(\frac{\partial v}{\partial x} + \frac{\partial u}{\partial y}\right)}_{=0} \mathrm{d}x\mathrm{d}y = 0 \qquad (7.2.82)$$

Thus our integral is reduced in the particular case of a closed path:

$$F(z) = \mathrm{i}\oint (v\mathrm{d}x + u\mathrm{d}y) \qquad (7.2.83)$$

and... reusing Green's theorem for this imaginary part:

$$\oint (v\mathrm{d}x + u\mathrm{d}y) = \int_S \left(\frac{\partial u}{\partial x} - \frac{\partial v}{\partial y}\right) \mathrm{d}x\mathrm{d}y \qquad (7.2.84)$$

However, if the function is holomorphic (for reminder that is to say differentiable at every point of the complex plane or an open subset of it) and thus satisfies the Cauchy-Riemann equations we get immediately:

$$\int_S \underbrace{\left(\frac{\partial u}{\partial x} - \frac{\partial v}{\partial y}\right)}_{=0} \mathrm{d}x\mathrm{d}y \qquad (7.2.85)$$

and we thus obtain the "Cauchy theorem", or "Cauchy-Goursat theorem" for its generalized version for non continuous functions, which says that if a function is holomorphic (thus satisfying the Cauchy-Riemann equations) and integrated on a closed contour then:

$$\boxed{\oint f(z)\mathrm{d}z = \oint (u + \mathrm{i}v)\mathrm{d}z = 0} \qquad (7.2.86)$$

As a corollary (without proof), any function that satisfies the above relation is holomorphic (in the whole complex plane or an open subset of it).

This result gives the possibility in certain fields like quantum physics fields (we think of the Yukawa potential that is not yet treated in this textbook in detailed) to calculate complicated real definite integrals using the above property. The idea is when choosing the closed contour of the path integral to play to make the real definite integral only as a part only of the path (by generalizing to the complex case) and by equality with zero we deduce its value thanks to the other parts of the integrals of the chosen path (parts that are obviously simple to calculate).

In other words, the idea is to calculate by difference! The difficulty residing in practice in finding the function $f(z)$ and the closed contour that permits to make appear the function $f(x)$ of the researched definite integral...

Using this result, let us make a very important academic example which will be useful later (but who has no connection with the case of calculating a real definite integral).

✍**Example:**

Let us calculate:

$$\oint \frac{\mathrm{d}z}{z} \tag{7.2.87}$$

For this purpose, we will use the simplification that consist to remember (see section Numbers page 251) that:

$$z = re^{\mathrm{i}\theta} \tag{7.2.88}$$

Therefore:

$$\mathrm{d}z = r\mathrm{i}e^{\mathrm{i}\theta}\mathrm{d}\theta \tag{7.2.89}$$

We can then write the path integral as:

$$\oint \frac{\mathrm{d}z}{z} = \int \frac{r\mathrm{i}e^{\mathrm{i}\theta}\mathrm{d}\theta}{re^{\mathrm{i}\theta}} = \mathrm{i}\mathrm{d}\theta \tag{7.2.90}$$

Or as on a closed path differentiable at any point (without nodes) the angle to make a full turn will necessarily be between 0 and $+\pi$. It comes then:

$$\oint \frac{\mathrm{d}z}{z} = \int\limits_0^{2\pi} \mathrm{d}\theta = 2\pi\mathrm{i} \tag{7.2.91}$$

Before we continue by noticing a very interesting and important fact that we will detail later formally: An integral (we do not speak of primitive but of integral!) of the type $1/x$ in $\mathbb{R}$ would not be calculable. But now if we generalize the concept of $\mathbb{C}$, we see that we get go around the singularity via a path integral that enclose the singularity. And ... and ... in our previous calculation z might have only the real value and not the imaginary one (so z reduce to x). So the integral of $1/x$ becomes calculable and has a result in the set of complex numbers which is remarkable!

Some mathematicians interpret this by figuring that $1/x$ is a flat projection of a three-dimensional space in which the imaginary axis is perpendicular to the plane $\mathbb{R}^2$ (see figures below). Hence the fact that $1/x$ can integrated in the set $\mathbb{C}$.

Finally, let us indicate that $1/z$ is holomorphic on the whole complex plane except on 0 (the derivative being the same as $1/x$). Then the function $1/z$ is thus not $\mathbb{C}$-differentiable!

This being done, let us do an important and similar case with the following path integral:

$$\oint \frac{1}{z - z_0}\mathrm{d}z \tag{7.2.92}$$

where z_0 is a constant complex number. Let us write:

$$z - z_0 = \rho e^{\mathrm{i}\varphi} \Rightarrow \frac{\mathrm{d}z}{\mathrm{d}\varphi} = \rho\mathrm{i}e^{\mathrm{i}\varphi} \Rightarrow \mathrm{d}z = \rho\mathrm{i}e^{\mathrm{i}\varphi}\mathrm{d}\varphi \tag{7.2.93}$$

We can then write if we make one turn counter clockwise:

$$\oint \frac{\mathrm{d}z}{z-z_0}=\int \frac{\rho \mathrm{i}e^{\mathrm{i}\varphi}\mathrm{d}\varphi}{\rho e^{\mathrm{i}\varphi}}=\mathrm{i}\int \mathrm{d}\varphi=2\pi\mathrm{i} \tag{7.2.94}$$

which is valid only if our integration path avoids z_0 what otherwise there is a singularity. This latter integral is a little simplistic generalization of the previous one.

Now let us show the important theorem that interests us since the beginning of this section using many proven results so far!

We know that if a function $f(z)$ satisfies the Cauchy-Riemann equations, then if we carefully avoid the value z_0 (as in the above calculations), the expression:

$$\frac{f(z)-f(z_0)}{z-z_0} \tag{7.2.95}$$

is differentiable at all points except in on z_0 (where the expression is no longer holomorph) is name a "singularity".

Indeed, take a holomorphic function $f(z)$ satisfying Cauchy-Riemann equation and subtract a constant $(f(z_0))$ does not change the fact that the expression (in this case the numerator in previous relationship) remains holomorphic. Finally, multiply it by a fraction (the denominator of the above equation) which is also holomorph gives a holomorphic function. But singularities can then appear, we then speak of "meromorphic functions" (this is the ratio of two holomorphic functions).

Remark

A meromorphic function is a function holomorphic in the whole complex plane, except possibly on a set of isolated points each of which is a pole (singularity) for the function (see further below for the concept of pole/singularity). The gamma function (see the plot in the Differential and Integral Calculus section at page **??**) is a famous example of meromorphic function!

So if we take the path integral on a closed path avoiding z_0, the Cauchy theorem gives us immediately (remember the proof above):

$$\oint \frac{f(z)-f(z_0)}{z-z_0}\mathrm{d}z=0 \tag{7.2.96}$$

However, this can also be written after rearrangement of terms:

$$\oint \frac{f(z)}{z-z_0}\mathrm{d}z=f(z_0)\oint \frac{1}{z-z_0}\mathrm{d}z \tag{7.2.97}$$

Therefore:

$$f(z_0)=\frac{1}{\displaystyle\oint \frac{1}{z-z_0}\mathrm{d}z}\oint \frac{f(z)}{z-z_0}\mathrm{d}z \tag{7.2.98}$$

But we have proved above that:

$$\oint \frac{\mathrm{d}z}{z-z_0}=2\pi\mathrm{i} \tag{7.2.99}$$

Then we get the result named "Cauchy's integral theorem", or more rarely "Cauchy formula" (of which there is a generalized result we will prove later below):

$$\boxed{f(z_0)=\frac{1}{2\pi\mathrm{i}}\oint\frac{f(z)}{z-z_0}\mathrm{d}z} \tag{7.2.100}$$

In fact, in practice all the subtlety is to be able to take back a given holomorphic function $g(z)$ (which therefore satisfies the Cauchy-Riemann equations) by manipulating it in a form of the type:

$$g(z)=\frac{f(z)}{z-z_0} \tag{7.2.101}$$

when its possible... then the calculation of its path integral (closed path) becomes extremely simple since it will be equal to:

$$2\pi\mathrm{i}f(z_0) \tag{7.2.102}$$

by the Cauchy's integral theorem!

Remark

So we know how to calculate the value of a path integral of an expression that is not holomorph but for which the numerator is holomorph!

Caution! The sign of the value of a path integral will depend on the direction in which its integration path will be done. If the direction is straightforward (that is to say "counter-clockwise") its sign will be positive; if on the contrary the direction is clockwise his sign will be negative. You probably think that this information is irrelevant since this value is usually zero. Yes... it is, but we will see later the importance of this information when referring to the calculation of what we name the "residuals".

✍**Example:**

An important application example is named the "Gauss' mean value theorem" that states given $f(z)$ an analytic function on and inside a disk $C_r : |z - z_0| = r$, then:

$$f(z_0) = \frac{1}{2\pi} \int_0^{2\pi} f(z_0 + re^{\mathrm{i}\theta}) \mathrm{d}\theta \tag{7.2.103}$$

Indeed, from the Cauchy's integral relation we have (we simply make the change of variable $z = z_0 + re^{\mathrm{i}\theta}$):

$$\begin{aligned} f(z_0) &= \frac{1}{2\pi\mathrm{i}} \oint_{C_r} \frac{f(z)}{z - z_0} \mathrm{d}z) = \frac{1}{2\pi\mathrm{i}} \int_0^{2\pi} \frac{f(z_0 + re^{\mathrm{i}\theta})\mathrm{i}re^{\mathrm{i}\theta}}{(z_0 + re^{\mathrm{i}\theta}) - z_0} \mathrm{d}\theta = \frac{1}{2\pi\mathrm{i}} \int_0^{2\pi} \frac{f(z_0 + re^{\mathrm{i}\theta})\mathrm{i}re^{\mathrm{i}\theta}}{re^{\mathrm{i}\theta}} \mathrm{d}\theta \\ &= \frac{1}{2\pi} \int_0^{2\pi} f(z_0 + re^{\mathrm{i}\theta}) \mathrm{d}\theta \end{aligned} \tag{7.2.104}$$

There is a similar relation for the derivative $f'(z_0)$ to that given by the Cauchy's integral theorem. Let us see this:

$$\begin{aligned} f'(z_0) &= \lim_{h \to 0} \frac{f(z_0 + h) - f(z_0)}{h} \\ &= \lim_{h \to 0} \left(\frac{f(z_0 + h)}{h} - \frac{f(z_0)}{h} \right) = \lim_{h \to 0} \frac{1}{h} (f(z_0 + h) - f(z_0)) \\ &= \lim_{h \to 0} \frac{1}{h} \left(\frac{1}{2\pi\mathrm{i}} \oint \frac{f(z)}{z - (z_0 + h)} \mathrm{d}z - \frac{1}{2\pi\mathrm{i}} \oint \frac{f(z)}{z - z_0} \mathrm{d}z \right) \\ &= \lim_{h \to 0} \frac{1}{2\pi\mathrm{i}h} \left(\oint \frac{f(z)\mathrm{d}z}{z - z_0 - h} - \oint \frac{f(z)\mathrm{d}z}{z - z_0} \right) \\ &= \lim_{h \to 0} \frac{1}{2\pi\mathrm{i}h} \left(\oint \frac{f(z)\mathrm{d}z}{z - z_0 - h} \frac{(z - z_0)}{(z - z_0)} - \oint \frac{f(z)\mathrm{d}z}{z - z_0} \frac{(z - z_0 - h)}{(z - z_0 - h)} \right) \\ &= \lim_{h \to 0} \oint \frac{1}{2\pi\mathrm{i}h} \frac{f(z)\left[(z - z_0) - (z - z_0 - h)\right]\mathrm{d}z}{(z - z_0 - h)(z - z_0)} = \lim_{h \to 0} \oint \frac{1}{2\pi\mathrm{i}h} \frac{hf(z)\mathrm{d}z}{(z - z_0 - h)(z - z_0)} \end{aligned} \tag{7.2.105}$$

Therefore:

$$f'(z_0) = \frac{1}{2\pi\mathrm{i}} \oint \frac{f(z)\mathrm{d}z}{(z - z_0)^2} \tag{7.2.106}$$

thereby continuing, we have:

$$\begin{aligned} f''(z_0) &= \frac{2}{2\pi\mathrm{i}} \oint \frac{f(z)\mathrm{d}z}{(z - z_0)^3} \\ f'''(z_0) &= \frac{6}{2\pi\mathrm{i}} \oint \frac{f(z)\mathrm{d}z}{(z - z_0)^4} \end{aligned} \tag{7.2.107}$$

In short, we therefore note that:

$$\boxed{f^{(n)}(z_0)=\frac{\mathrm{d}^n f(z_0)}{\mathrm{d}z^n}=\frac{n!}{2\pi\mathrm{i}}\oint\frac{f(z)}{(z-z_0)^{n+1}}\mathrm{d}z} \tag{7.2.108}$$

which is the "Generalized Cauchy's integral theorem".

This result is very powerful because it shows that holomorphic functions are infinitely differentiable (because of the denominator), that is to say analytical, and it is much more difficult to find an equivalent theorem with such simple conditions for real functions.

If we now return to our Taylor expansion of a complex function:

$$f(z)=\sum_{i=0}^{+\infty}\frac{1}{n!}\frac{\mathrm{d}^n f(z_0)}{\mathrm{d}z^n}(z-z_0)^n \tag{7.2.109}$$

um ... and what do we see here? Well this !:

$$\begin{aligned}f(z)&=\sum_{i=0}^{+\infty}\frac{1}{n!}\frac{\mathrm{d}^n f(z_0)}{\mathrm{d}z^n}(z-z_0)^n=\sum_{i=0}^{+\infty}\frac{1}{n!}\frac{n!}{2\pi\mathrm{i}}\oint\frac{f(z)\mathrm{d}z}{(z-z_0)^{n+1}}(z-z_0)^n\\&=\sum_{i=0}^{+\infty}\frac{1}{2\pi\mathrm{i}}\oint\frac{f(z)}{(z-z_0)^{n+1}}\mathrm{d}z(z-z_0)^n=\sum_{i=0}^{+\infty}c_n(z-z_0)^n\end{aligned} \tag{7.2.110}$$

It follows the following relation named "Laurent series in positive powers" (there is a more generalized version will be prove later below):

$$\boxed{f(z)=\sum_{i=0}^{+\infty}c_n(z-z_0)^n} \tag{7.2.111}$$

that gives us the formal expression of a complex function in the form of infinite series of integer powers near a point z_0 of the complex plane with therefore:

$$\boxed{c_n=\frac{1}{2\pi\mathrm{i}}\oint\frac{f(z)}{(z-z_0)^{n+1}}\mathrm{d}z=\frac{f^n(z_0)}{n!}} \tag{7.2.112}$$

Remembering that $\mathrm{d}^n f(z_0)/\mathrm{d}z^n$ can be written equivalently $f^n(z_0)$, we see that all the two previous relations gives us the Taylor series expansion that we had obtained in real analysis (see section Sequences and Series page 1696) and that was:

$$\boxed{f(z)=\sum_{i=0}^{+\infty}\frac{1}{n!}\frac{\mathrm{d}^n f(z_0)}{\mathrm{d}z^n}(z-z_0)^n} \tag{7.2.113}$$

Thus, the Taylor series in $\mathbb{R}$ are a special case of Laurent series that are in $\mathbb{C}$!!!

This result is quite remarkable because it also shows that we can use the path integral in the complex plane for calculating the coefficients c_n of the Laurent series instead of calculating the derivatives of order n of the function f if these latter are too complicated to determine. Or vice versa... calculate a simple derivation instead of calculating a headache type path integral (typically the case in physics) using the fact that:

$$\oint \frac{f(z)}{(z-z_0)^{n+1}}\mathrm{d}z = 2\pi\mathrm{i}\frac{f^{(n)}(z_0)}{n!} \tag{7.2.114}$$

The only unfortunate point being that the latter relation is calculable only if we can put the function in path line integral in the form:

$$\frac{f(z)}{(z-z_0)^{n+1}} \tag{7.2.115}$$

where n is a positive or null integer. This is honestly far from to be easy in most cases! The idea would be to find a general path for line integral, valid for any function $f(z)$ such that the denominator (which additionally contains a singularity on z_0) disappears. That would be ideal ... but we need a track ... and it will come from the study of the convergence of series of complex powers. Let's see what it is with a qualitative approach!

7.2.4.1 Convergence of a complex series

We saw in the section of Sequences and Series that many real functions could be expressed in Maclaurin series (special case of the Taylor series on $x_0=0$) in the form:

$$f(x)=\sum_{k=0}^{+\infty} a_k x^k \tag{7.2.116}$$

We also showed, by example the only, that this series expansion of infinite powers was valid for some real functions only in a certain domain of definition named "radius of convergence".

Even if this radius of convergence can be determined more or less easily in each case, there are some baffling examples that could not in the early 119th century (holocene calendar) be understood without complex analysis.

Let's see a simple example to understand what kind of problem it is. Consider for this the two functions:

$$g(x)=\frac{1}{1-x^2} \quad \text{and} \quad h(x)=\frac{1}{1+x^2} \tag{7.2.117}$$

and before continuing our example, recall that we have proved in the section of Sequences and Series the relation:

$$S_n=u_0+u_1+u_2+\ldots+u_n=\frac{u_0-u_{n+1}}{1-q}=u_0\frac{1-q^{n+1}}{1-q} \tag{7.2.118}$$

relative to a geometric series, that is to say a series whose terms are of the type:

$$u_n=u_0q^n \tag{7.2.119}$$

Therefore it comes immediately if $n\rightarrow+\infty$ and $q\in]-1,+1[$:

$$S_\infty=u_0+u_1+u_2+\ldots+u_{+\infty}=\sum_{k=0}^{+\infty}u_k=u_0\frac{1-q^{+\infty+1}}{1-q}=u_0\frac{1-0}{1-q}=\frac{u_0}{1-q} \tag{7.2.120}$$

if $u_0=1$, we get:

$$\sum_{k=0}^{+\infty} u_k=\sum_{k=0}^{+\infty} u_0 q^k=\sum_{k=0}^{+\infty} u_0=\frac{1}{1-q} \tag{7.2.121}$$

So if we change the notation, we have:

$$\frac{1}{1-x}=\sum_{n=0}^{+\infty} x^n \tag{7.2.122}$$

Then it comes immediately:

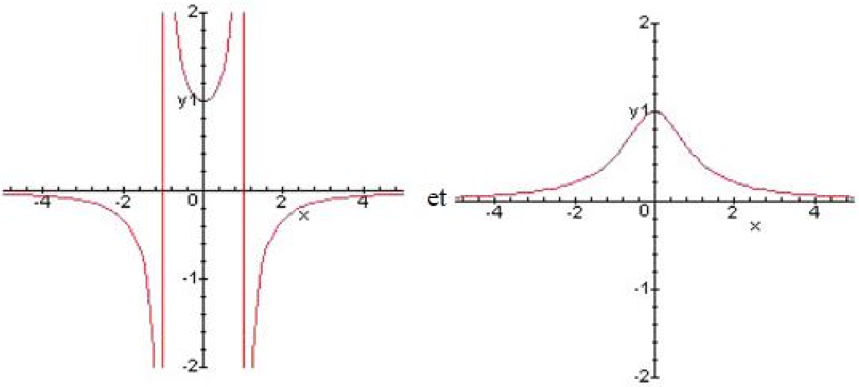
$$g(x)=\sum_{n=0}^{+\infty}(x^2)^n=\sum_{n=0}^{+\infty}(x^2)^n \quad \text{and} \quad h(x)=\sum_{n=0}^{+\infty}(-x^2)^n=\sum_{n=0}^{+\infty}(-1)^n x^{2n} \tag{7.2.123}$$

Therefore the two previous functions $g(x)$ and $h(x)$ are defined for a infinite series expansion in powers only in radius of convergence $x\in]-1,+1[$.

We would get the same result by making a Maclaurin series expansion!

We see that there is trivially for $g(x)$ two singularities that are $x=\{-1,+1\}$ by cons, basically we do not see trivial singularities for $h(x)$ if we reason only in $\mathbb{F}$ so it can be hard for the latter function to understand the origin of the radius of convergence!

Indeed, if we plot these two functions in $\mathbb{R}$ with Maple™ 4.00b we get respectively:



hence the problem of why there is still implicitly a radius of convergence $x\in]-1,+1[$ for $h(x)$???

An even more blatantly way to highlight the problem, is to show the approach of these two functions by a Maclaurin series expansion with ten terms.

For $g(x)$ we get for example:

```
>with(plots):
>xplot:= plot(1/(1-x^2),x=-5..5,thickness=2,color=red):
>tays:= plots[display](xplot):
```

```
>for i from 1 by 2 to 10 do
tpl:= convert(taylor(1/(1-x^2), x=0,i),polynom):
tays:= tays,plots[display]([xplot,plot(tpl,x=-5..5,y=-2..2,
color=black,title=convert(tpl,string))])
od:
>plots[display]([tays],view=[-5..5,-2..2]);
```

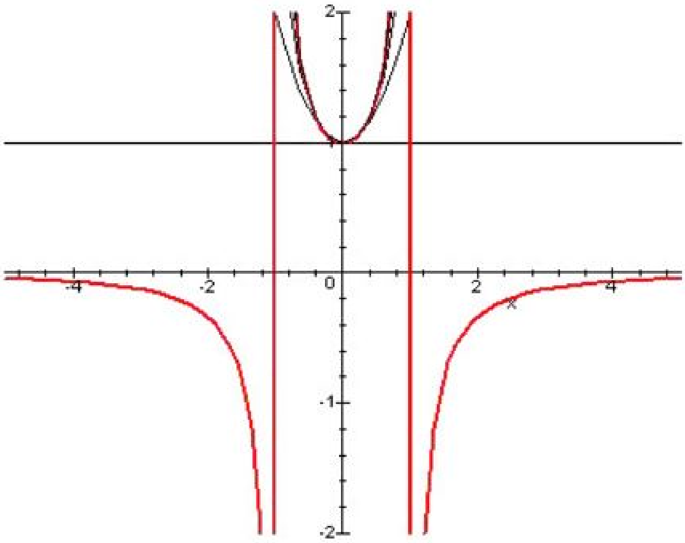


Figure 7.82: **Plane representation of the function g to visualize the problem**

where we see well that the Maclaurin series (or expression in power series) does not converge outside $x \in]-1,+1[$ which can be intuitive because of both singularities.

For $h(x)$ we have by cons:

```
 > with(plots):
> xplot:= plot(1/(1+x^2),x=-5..5,thickness=2,color=red):
> tays:= plots[display](xplot):
> for i from 1 by 2 to 10 do
tpl:= convert(taylor(1/(1+x^2), x=0,i),polynom):
tays:= tays,plots[display]([xplot,plot(tpl,x=-5..5,y=-2..2,
color=black,title=convert(tpl,string))])
od:
> plots[display]([tays],view=[-5..5,-2..2]);
```

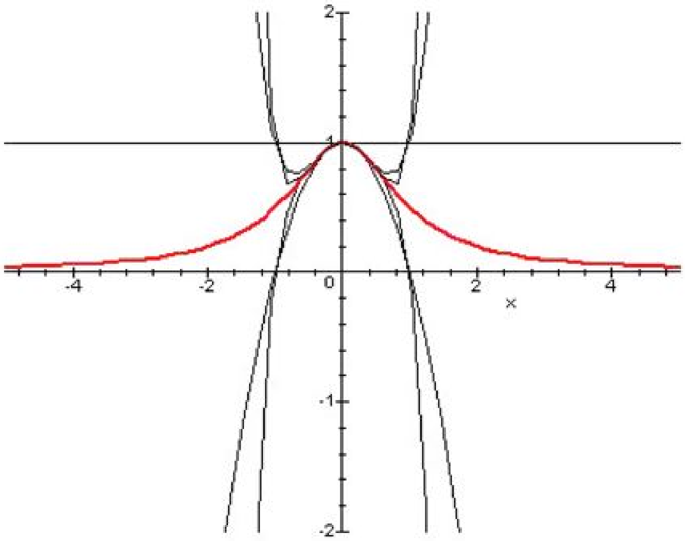

Figure 7.83: **Surprisingly, here the Maclaurin series (in black) does not converge**

where we see well that the Maclaurin series (or the expression in power series) does not converge either outside $x \in]-1,+1[$ which was unsettling and against-intuitive at the beginning of the history of real analysis.

Today even a high school student knows that he can also think in $\mathbb{C}$ and that $\mathbb{R} \subset \mathbb{C}$. So the real analysis is just a special case and restricted of the field of complex analysis. The fact to extend the domain of a given analytic function is named "analytic continuation". As we will see just now analytic continuation often succeeds in defining further values of a function, for example in a new region where an infinite series representation in terms of which it is initially defined becomes divergent!

The singularity for $h(x)$ in $\mathbb{C}$ comes that latter is then written:

$$h(z) = \frac{1}{1+z^2} \tag{7.2.124}$$

and there are therefore two singularities $z = \{-\mathrm{i}, +\mathrm{i}\}$ that we see well if we represent:

$$|h(z)| = \left|\frac{1}{1+z^2}\right| \tag{7.2.125}$$

with Maple™ 4.00b (fortunately we now have the equivalent of a microscope in mathematics with Maple™...):

```
>plot3d(abs(1/(1+(re+I*im)^2)),re=-3..3,im=-3..3,view=[-2..2,-2..2,-2..2]
,orientation=[-130,70],contours=50,style=PATCHCONTOUR,axes=frame,
grid=[100,100],numpoints=10000);
```

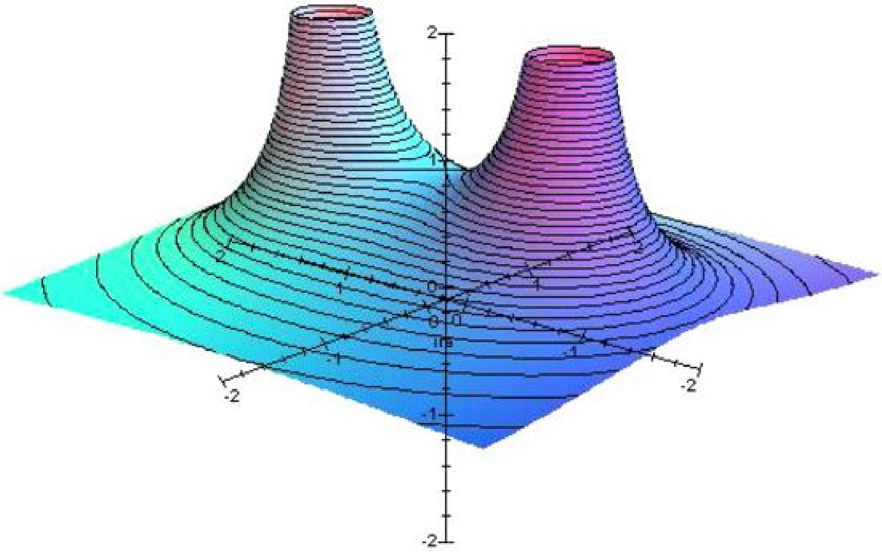

Figure 7.84: **Complex representation of the function h to highlight the reason for the divergence**

where we can see the two singularities on the imaginary axis and the function $h(x)$ on the real axis (between the two peaks). So when we develop a function in power series, we conclude that the radius of convergence is defined by the whole complex plane and not by the traditional axis of the real analysis.

This makes it more natural to understand why we were talking in the section of Sequences and Series of "radius" as seen from above, we have in the complex plane:

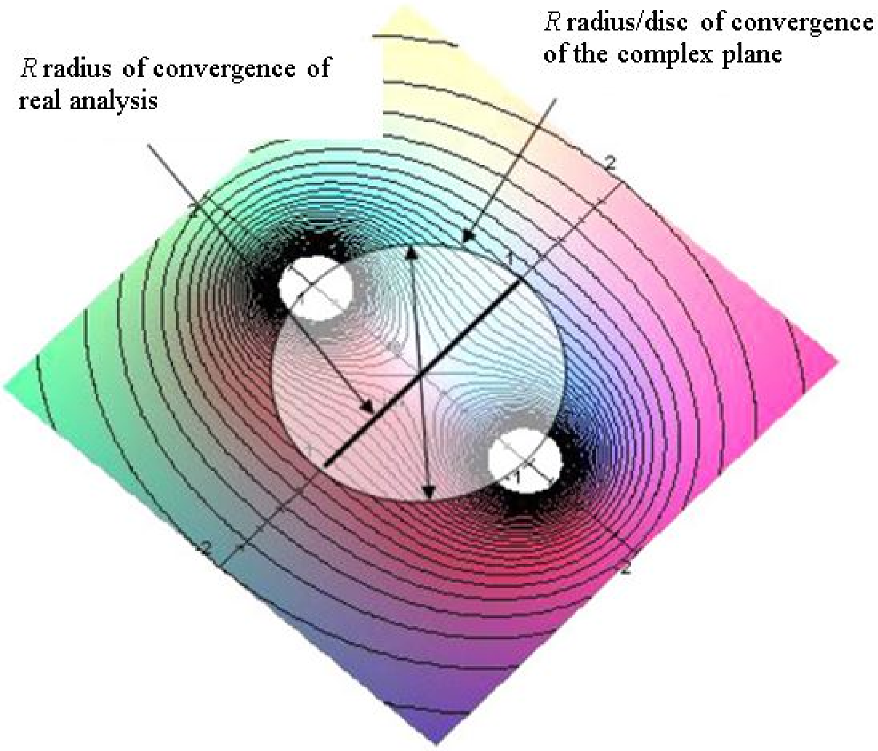

Figure 7.85: **Representation of the various convergence of radius of $h(z)$**

hence the fact that we are talking sometimes about (open) convergence disk and sometimes of (open) convergence radius. Moreover, we notice on the chart that the domain of convergence is convex (any couple of points of the domain can be connected by a straight line that is in the area of convergence).

Remark

Let us Recall that a subset, interval or "open" disc means that we do not take its border as we have seen in the section Topology.

Then we understand better why the Taylor series does not converge trivially for $h(x)$: it must converge on the whole disc of the complex plane and not just converge on the real axis!

From all this we deduce that our Laurent series in positive powers proved above:

$$f(z)=\sum_{k=0}^{+\infty}c_n(z-z_0)^n \tag{7.2.126}$$

not necessarily converge, unsurprisingly... on the whole complex plane (just like the Taylor series on the real line as this is the equivalent!) but sometimes only in a opened subdomain (convex?) of this plane around z_0 (which in the particular example taken above was obviously: 0).

With our function $h(x)$ expressed using a development of Maclaurin with 5 terms, we see immediately with Maple™ 4.00b that on the borders of the square inscribed in the disc of convergence, the series does not converge and we're guessing the start of the two singularities:

```
>plot3d(abs(1-(re+I*im)^2+(re+I*im)^4-(re+I*im)^6+(re+I*im)^8),
re=-0.7..0.7,im=-0.7..0.7,view=[-1.5..1.5,-1.5..1.5,0..1.5]
,orientation=[-130,70],contours=50,style=PATCHCONTOUR,axes=frame,
grid=[100,100],numpoints=10000);
```

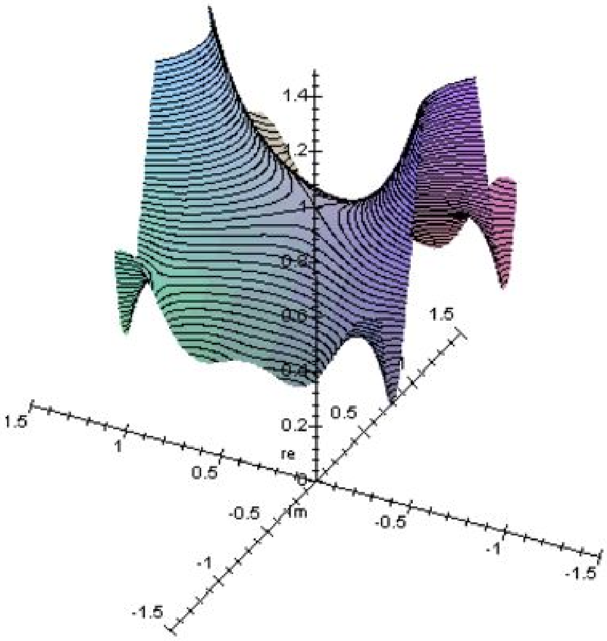

Figure 7.86: Focus on the complex representation to understand the reason for the divergence

a little outside the disc of convergence, we obviously have a little bit nonsense:

```
>plot3d(abs(1-(re+I*im)^2+(re+I*im)^4-(re+I*im)^6+(re+I*im)^8),re=-3..3,
im=-3..3,view=[-1.5..1.5,-1.5..1.5,0..1.5],orientation=[-130,70]
,contours=50,style=PATCHCONTOUR,axes=frame,grid=[100,100],numpoints=10000);
```

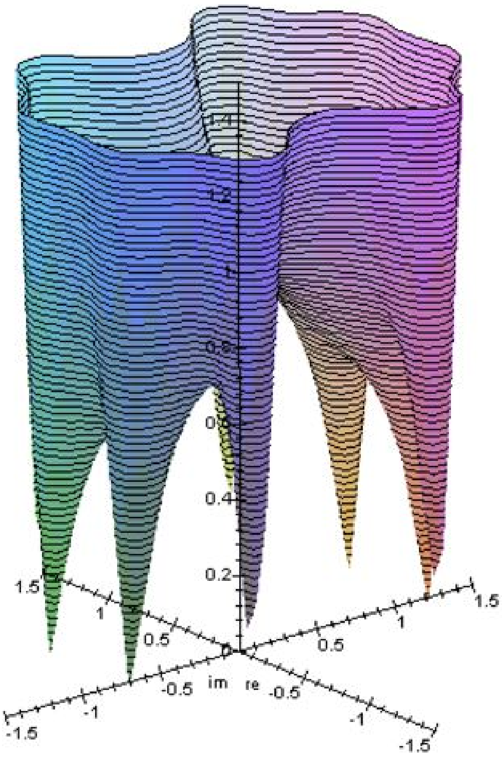

Figure 7.87: This diverges ... (stalactites ???)

There is still something interesting to try ... since we are now on a plane, not a straight line right (axis), it is possible for us to make the Taylor expansion around a singularity z_0 by deforming the disk in a convex crown/ring simply connected as shown below (the crown/ring being the simplest simply convex geometry arising from the deformation of a disk):

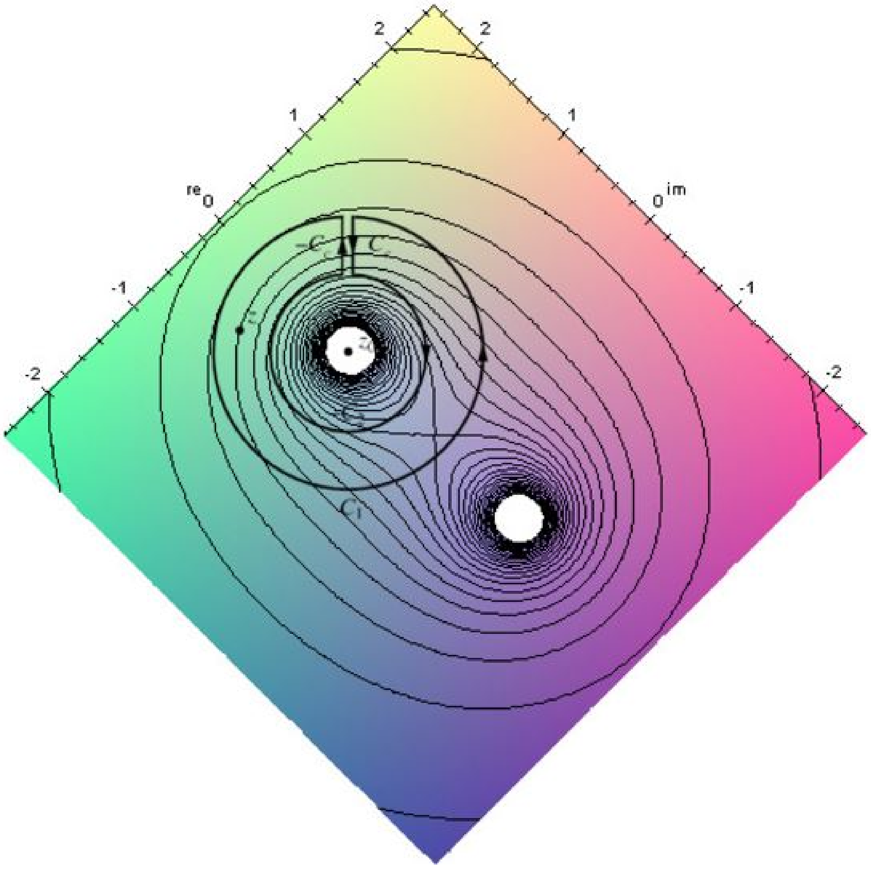

Figure 7.88: **Representation of the deformation of a disc in a crown/ring**

The advantage of this is to deform the area of convergence on the whole complex plane by avoiding (bypassing) all the singularities. Thus, unlike the Taylor series that are only valid on an interval of the x-axis, we would have a new type of series describing a function absolutely everywhere, that is to say before AND after (so around...) singularities!

So obviously we will require that in the deformed crown above the function is always holomorph and analytical (as in the initial convex disc). Before determining what we are going down (generalized Laurent series!), we must first do a study of the decomposition of path integral:

7.2.5 Path Decomposition

The path integrals as given previously can also be written in another form almost classical and used many times in the literature.

Let us see this. First, remember that we have just proved in the special case of a holomorphic function that:

$$\oint f(z)\mathrm{d}z=0 \tag{7.2.127}$$

But a closed path can be seen as a path having a round trip:

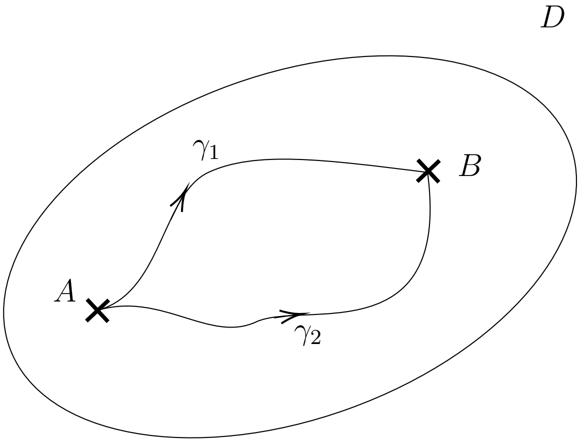

Figure 7.89: **Representation of a closed path with round trip**

Therefore we can write:

$$\int\limits_{\gamma_1} f(z)\mathrm{d}z-\int\limits_{\gamma_2} f(z)\mathrm{d}z=0\Leftrightarrow\int\limits_{\gamma_1} f(z)\mathrm{d}z=\int\limits_{\gamma_2} f(z)\mathrm{d}z \tag{7.2.128}$$

And now comes what interest us... for this purpose let us focus one of the path integral of the type:

$$\int\limits_{\gamma} f(z)\mathrm{d}z \tag{7.2.129}$$

We already well known (1st form of notation) that any complex number z of the type:

$$z=x+\mathrm{i}y \tag{7.2.130}$$

can be (2nd form of notation) written as (Euler form):

$$z(x,y)=x+\mathrm{i}y=r\cos(\theta)+\mathrm{i}\sin(\theta)=re^{\mathrm{i}\theta}=z(r,\theta) \tag{7.2.131}$$

and to integrate on a path, nothing prevent us to choose a path where r (the module) would be fixed and θ variable (we could not have the possibility to do this with the 1st form because by modifying the imaginary or real part, we can't get be guarantee to get a nice smooth curve but this is possible with the Euler form of a complex number)!

Therefore we have:

$$z(\theta)=re^{\mathrm{i}\theta} \tag{7.2.132}$$

We write then naturally:

$$\int\limits_{\gamma} f(z)\mathrm{d}z=\int\limits_{\gamma} f(z(\theta))\mathrm{d}z(\theta) \tag{7.2.133}$$

and as:

$$z'(\theta)=\dfrac{\mathrm{d}z}{\theta}\Leftrightarrow \mathrm{d}z=z'(\theta)\mathrm{d}\theta \tag{7.2.134}$$

Therefore:

$$\int\limits_{\gamma} f(z)\mathrm{d}z=\int\limits_{\gamma} f(z(\theta))z'(\theta)\mathrm{d}\theta \tag{7.2.135}$$

That we often find in the following form in the literature:

$$\boxed{\int\limits_{\gamma} f(z)\mathrm{d}z=\int\limits_{\gamma} f(z(t))\dot{z}(t)\mathrm{d}t} \tag{7.2.136}$$

7.2.5.1 Inverse Path

If C is a curve going from a point P to a point Q, then we denote by C^{-} the same curve but travelled from Q to P.

Now we will parametrize C^{-}.

If $C(t)$ it is the curve defined on $[a,b]$, then we define the curve $C^{-}(t)$ on $[a,b]$ by:

$$C^{-}(t)=C(a+b-t) \tag{7.2.137}$$

Indeed we have with this parametrization:

$$C^{-}(a)=C(a+b-a)=C(b)\quad \text{and}\quad C^{-}(b)=C(a+b-b)=C(a) \tag{7.2.138}$$

and when t increases from a to b, $a+b-t$ decreases from b to a. C^{-} is therefore only C but travelled in the opposite direction.

We then have using the last proof:

$$\int\limits_{C^{-}} f(C^{-})\mathrm{d}C^{-}=\int\limits_{a}^{b} f(C^{-}(t))C'^{-}(t)\mathrm{d}t=\int\limits_{a}^{b} f(C(a+b-t))C'(a+b-t)\mathrm{d}t \tag{7.2.139}$$

Let us put:

$$u=a+b-t \tag{7.2.140}$$

Therefore:

$$\mathrm{d}u = -\mathrm{d}t \tag{7.2.141}$$

Then we have:

$$\begin{aligned}\int\limits_{C^-} f(C^-)\mathrm{d}C^- &= \int\limits_a^b f(C(a+b-t))C'(a+b-t)\mathrm{d}t = \int\limits_a^b f(C(u))C'(u)(-\mathrm{d}u)\\ &= -\int\limits_a^b f(C(u))C'(u)\mathrm{d}u = -\int\limits_a^b f(C)\mathrm{d}C\end{aligned} \tag{7.2.142}$$

Therefore if C^- and C are the paths of the same function but travel in the opposite direction, we have by taking our conventional notation (caution! In the second term it is implicit that the parametrization is different from the first one!):

$$\int\limits_{\gamma} f(z)\mathrm{d}z = -\int\limits_{\gamma^-} f(z)\mathrm{d}z \tag{7.2.143}$$

Therefore:

$$\boxed{\int\limits_{\gamma} f(z)\mathrm{d}z + \int\limits_{\gamma^-} f(z)\mathrm{d}z = 0} \tag{7.2.144}$$

this is why we often say that the sign of the value of a line integral will depend on the direction in which its integration path is travel. If the direction is straightforward (that is to say "counter-clockwise") its sign will be positive; if on the contrary the direction is clockwise its sign will be negative (see section Differential and Integral Calculus page 1586).

7.2.6 Laurent Series

This last relation obtained, we can return to the deformation of our disc of convergence in a crown. We recall that initially the idea is to have the analytical expression of a function as an infinite series of powers in a limited area around a singularity point and all this... in the purpose to be able to calculate for physicists complex path integrals through a method using the properties of complex series!

Let's start with the point (2) that is to say have an infinite power series for a path integral, which will take us more easily to point (1) that is to say get the an analytical expression of a function around a singularity point, by zooming on our crown:

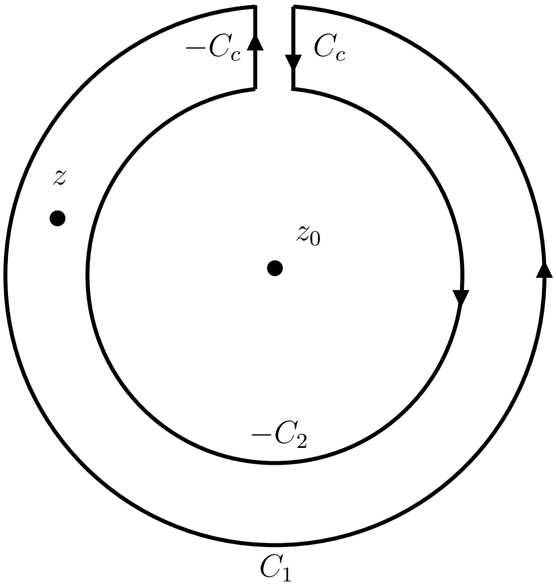

Figure 7.90: **Zoom on our crown from our starting example**

We therefore have if the function f is analytic and holomorphic in the crown of outer radius R and inside radius r, the following path curvilinear integral in the crown as we proved above (we change notation: $z = z'$ and $z_0 = z$):

$$f(z) = \frac{1}{2\pi\mathrm{i}} \oint \frac{f(z')}{z'-z}\mathrm{d}z' \tag{7.2.145}$$

therefore we denote now by z the point where we want to know the function and z' variable of which f depends. This notation change will be justified later for a purely practical reason.

The crown can be broken down into four paths:

$$f(z) = \frac{1}{2\pi\mathrm{i}} \int\limits_{C_1} \frac{f(z')}{z'-z}\mathrm{d}z' + \frac{1}{2\pi\mathrm{i}} \int\limits_{C_c} \frac{f(z')}{z'-z}\mathrm{d}z' + \frac{1}{2\pi\mathrm{i}} \int\limits_{-C_c} \frac{f(z')}{z'-z}\mathrm{d}z' + \frac{1}{2\pi\mathrm{i}} \int\limits_{-C_2} \frac{f(z')}{z'-z}\mathrm{d}z' \tag{7.2.146}$$

If both segments C_c and $-C_c$ are infinitely close, they then correspond to the same path travelled once in a positive direction and once in the negative direction. As we have proved just above that:

$$\int\limits_{\gamma} f(z)\mathrm{d}z=-\int\limits_{\gamma^-} f(z)\mathrm{d}z \tag{7.2.147}$$

It therefore follows that:

$$\int\limits_{C_c} \frac{f(z')}{z'-z}\mathrm{d}z'=-\int\limits_{-C_c} \frac{f(z')}{z'-z}\mathrm{d}z' \tag{7.2.148}$$

Which brings us to write:

$$\begin{aligned} f(z)&=\frac{1}{2\pi\mathrm{i}}\int\limits_{C_1}\frac{f(z')}{z'-z}\mathrm{d}z'+\frac{1}{2\pi\mathrm{i}}\int\limits_{C_c}\frac{f(z')}{z'-z}\mathrm{d}z'-\frac{1}{2\pi\mathrm{i}}\int\limits_{C_c}\frac{f(z')}{z'-z}\mathrm{d}z'+\frac{1}{2\pi\mathrm{i}}\int\limits_{-C_2}\frac{f(z')}{z'-z}\mathrm{d}z'\\ &=\frac{1}{2\pi\mathrm{i}}\int\limits_{C_1}\frac{f(z')}{z'-z}\mathrm{d}z'-\frac{1}{2\pi\mathrm{i}}\int\limits_{C_2}\frac{f(z')}{z'-z}\mathrm{d}z'\\ &=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma_R}\frac{f(z')}{z'-z}\mathrm{d}z'-\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma_r}\frac{f(z')}{z'-z}\mathrm{d}z'=f_1(z)+f_2(z)\end{aligned} \tag{7.2.149}$$

where we have put a "+" between the last two terms, because as we shall see immediately, the convergence criterion associated with the traditional notation in this field of study, makes automatically emerge the sign "-".

For the two integral f_1,f_2, we know that the fraction can be written as a geometric series as already seen above. Effectively, starting from (now you will understand why we changed the notation):

$$\frac{1}{z'-z}=\frac{1}{(z'-z_0)+(z_0-z)}=\frac{1}{z'-z_0}\frac{1}{1-\dfrac{z-z_0}{z'-z_0}} \tag{7.2.150}$$

by assimilating:

$$x=\frac{z-z_0}{z'-z_0} \tag{7.2.151}$$

where as we have seen, the convergence requires that:

$$|z-z_0|\leq|z'-z_0| \tag{7.2.152}$$

so that x is lower in absolute value to 1.

We then see the infinite geometric series appearing:

$$\frac{1}{z'-z_0}=\frac{1}{z'-z_0}\left[1+\left(\frac{z-z_0}{z'-z_0}\right)+\left(\frac{z-z_0}{z'-z_0}\right)^2+\ldots+\left(\frac{z-z_0}{z'-z_0}\right)^n+\ldots\right] \tag{7.2.153}$$

Therefore:

$$\frac{1}{z'-z_0}=\frac{1}{z'-z_0}+\frac{z-z_0}{(z'-z_0)^2}+\frac{(z-z_0)^2}{(z'-z_0)^3}+\ldots+\frac{(z-z_0)^n}{(z'-z_0)^{n+1}}+\ldots \tag{7.2.154}$$

To come back to:

$$f_1(z)=\frac{1}{2\pi \mathrm{i}}\int\limits_{\gamma_R}\frac{f(z')}{z'-z}\mathrm{d}z' \tag{7.2.155}$$

we have in any point z inside the circle of radius R whose border is described by the variable z' and of center z_0 the convergence that is assured because:

$$|z-z_0|\leq|z'-z_0| \tag{7.2.156}$$

Then we can write:

$$f_1(z)=\frac{1}{2\pi \mathrm{i}}\int\limits_{\gamma_R}f(z')\left[\frac{1}{z'-z_0}+\frac{z-z_0}{(z'-z_0)^2}+\frac{(z-z_0)^2}{(z'-z_0)^3}+\ldots+\frac{(z-z_0)^n}{(z'-z_0)^{n+1}}+\ldots\right]\mathrm{d}z' \tag{7.2.157}$$

Integrating term by term integration, we highlight the development (already known):

$$f_1(z)=\sum_{n=0}^{+\infty}c_n(z-z_0)^n \tag{7.2.158}$$

with the definition of coefficients c_n, where n is a positive or null integer:

$$c_n=\frac{1}{2\pi \mathrm{i}}\int\limits_{\gamma_R}\frac{f(z')}{(z'-z_0)^{n+1}}\mathrm{d}z' \tag{7.2.159}$$

This development may do think to the development of Taylor in the sense that only positive (or zero) powers of $(z'-z_0)$ appear, but this is not Taylor development in the case of the crown! Indeed, c_n can not be written this time as:

$$c_n=\frac{f^n(z_0)}{n!} \tag{7.2.160}$$

since, by assumption, $f(z)$ is assumed analytic in the crown only and may therefore very well not be inside the small circle of radius r, in particular on z_0, in which case $f^n(z_0)$ may simply not exist (let us repeat that z is strictly constrained to be in the crown, therefore $r<|z|<R$). We will see later what happens when $f(z)$ is holomorphic in this disk and that, in particular, z_0 is not a singular point.

We still need to treat f_2. We then do the same type of development as for f_1, with the difference that now:

$$|z-z_0|>|z'-z_0| \tag{7.2.161}$$

when z' browse the small circle of radius r. To make a geometric series appear, we must write this time:

$$\frac{1}{z-z'}=-\frac{1}{z-z'}=\frac{1}{(z-z_0)-(z'-z_0)}=-\frac{1}{z-z_0}\frac{1}{1-\dfrac{z'-z_0}{z-z_0}} \tag{7.2.162}$$

Therefore:

$$\frac{1}{z-z'}=-\frac{1}{z-z_0}\frac{1}{1-\dfrac{z'-z_0}{z-z_0}}=-\frac{1}{z-z_0}\left[1+\left(\frac{z'-z_0}{z-z_0}\right)+\left(\frac{z'-z_0}{z-z_0}\right)^2+\ldots+\left(\frac{z'-z_0}{z-z_0}\right)^n+\ldots\right] \tag{7.2.163}$$

So we have:

$$\frac{1}{z-z'}=-\frac{1}{z-z_0}-\frac{z'-z_0}{(z-z_0)^2}-\frac{(z'-z_0)^2}{(z-z_0)^3}-\ldots-\frac{(z'-z_0)^n}{(z-z_0)^{n+1}}-\ldots \tag{7.2.164}$$

Integrating term by term, we highlight the (new) development:

$$f_2(z)=\sum_{n=1}^{+\infty}c_{-n}(z-z_0)^{-n} \tag{7.2.165}$$

with:

$$c_{-n}=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma_r}f(z')(z'-z_0)^{-n-1}\mathrm{d}z' \tag{7.2.166}$$

By changing n in $-n$ in the summation for f_2, we have for the sum $f_1(z)+f_2(z)$:

$$f(z)=\sum_{n=-\infty}^{+\infty}c_n(z-z_0)^n \tag{7.2.167}$$

with at this time two distinct c_n:

$$c_{n\geq 0}=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma_R}\frac{f(z')}{(z'-z_0)^{n+1}}\mathrm{d}z' \quad \text{and} \quad c_{n<0}=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma_r}f(z')(z'-z_0)^{-n-1}\mathrm{d}z' \tag{7.2.168}$$

We will now see that these two relations can be combined into one!

For this purpose if we observe well the last two relations, we find that they do not depend at all of z (!) and this is normal since the c_n are the coefficients of the series expansion of $f(z)$ and these are the same at any point of the domain of definition of the function where it is analytic!

So the two contours (circles) can be merged into only one circle since it is located in the crown and has for center z_0:

$$c_{n\geq 0}=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma_R}\frac{f(z')}{(z'-z_0)^{n+1}}\mathrm{d}z' \qquad (n=0,\pm 1,\pm 2,\ldots) \tag{7.2.169}$$

Furthermore, the attentive reader will have noticed that this contour does not even need to be a circle finally! It may be any geometry as long as it is closed and is located in an analytical area!

Thus, we get the two relations:

$$\boxed{\begin{aligned} f_{(z)}&=\sum_{n=-\infty}^{+\infty}c_n(z-z_0)^n\\ c_n&=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma_R}\frac{f(z')}{(z'-z_0)^{n+1}}\mathrm{d}z' \qquad (n=0,\pm 1,\pm 2,\ldots)\end{aligned}} \tag{7.2.170}$$

The two previous relation define the "general Laurent series". It is remarkable and differs from a Taylor series in the sense that it contains all the positive and negative integer powers and the coefficients c_n can a priori not be expressed with the derivatives of f.

The power series of $n \geq 0$ is named "regular part", the negative powers is commonly named "main part".

The series of negative powers converges uniformly everywhere outside γ_r, that of positive powers within γ_R. In total the development of Laurent converges uniformly in the common area, which is the crown and therefore also on the unique path γ.

Let us now show a point that we have mentioned above. If the circle contains no singularity, then all the coefficients:

$$c_{n<0} = \frac{1}{2\pi \mathrm{i}} \int\limits_{\gamma} f(z')(z'-z_0)^{-n-1} \mathrm{d}z' \qquad (7.2.171)$$

are zero. First note that $-n-1$ is a positive or zero integer, which we will denote by p such as:

$$c_{n<0} = \frac{1}{2\pi \mathrm{i}} \int\limits_{\gamma} f(z')(z'-z_0)^{p} \mathrm{d}z' \quad p \in \mathbb{N} \qquad (7.2.172)$$

We then have the following integrand along a closed path:

$$f(z')(z'-z_0)^p \qquad (7.2.173)$$

But, if we remove the singularity that requires $f(z')$ is holomorphic (and in anyway this is required by all initial developments of the Laurent series).

As $(z'-z_0)^p$ is polynomial with positive and not null integer powers and that as we know any polynomial satisfying these conditions is differentiable at least once without showing singularity. Thus this term is also holomorphic.

Assuming that the product of two holomorphic functions is holomorphic and that contour γ is closed, then we have using the following result proved above (for a holomorphic function):

$$\oint f(z) \mathrm{d}z = 0 \qquad (7.2.174)$$

the following immediate consequence:

$$\int\limits_{\gamma} f(z')(z'-z_0)^p \mathrm{d}z' = 0 \Rightarrow c_{n<0} = \frac{1}{2\pi \mathrm{i}} \int\limits_{\gamma} f(z')(z'-z_0)^p \mathrm{d}z' = 0 \qquad (7.2.175)$$

if there is no singularity in the small circle of the crown. We then fall back again on a development with only positive powers, the $c_{n\geq 0}$ this time being equal to:

$$c_n = \frac{f^n(z_0)}{n!} \qquad (7.2.176)$$

according to the generalized Cauchy's integral theorem proved earlier above. Conversely, we see well that this is the main part (when it exists!) which contains the information on the fact that f is not a priori holomorphic in the small disk. The existence of negative powers shows that f is clearly not bounded on z_0.

The classification of singularities of a function will be precisely based on the consideration of the characteristics of the main part of the Laurent development centered on a singular point of this function.

✍**Example:**

Let us see to what looks like the Laurent series of our famous example function:

$$f(z)=\frac{1}{1+z^2} \tag{7.2.177}$$

on a simply convex domain that would be the crown rounding the singularity i for example (we could have taken the second singularity $-\mathrm{i}$ but we had to choose one to not repeat twice the explanations below...). This is equivalent therefore to search the power series development of $z-\mathrm{i}$.

We will proceed as following:

$$f(z)=\frac{1}{1+z^2}=\frac{1}{(z+\mathrm{i})(z-\mathrm{i})} \tag{7.2.178}$$

For what will follow we will use:

$$f(z)=\frac{1}{(z+\mathrm{i})}=\frac{1}{2\mathrm{i}+(z-\mathrm{i})}=-\frac{\mathrm{i}}{2}\frac{1}{1-\dfrac{\mathrm{i}}{2}(z-\mathrm{i})} \tag{7.2.179}$$

The second fraction can be expressed as a geometric series if as we have already seen:

$$\left|\frac{\mathrm{i}}{2}\frac{1}{1-\dfrac{\mathrm{i}}{2}(z-\mathrm{i})}\right|<1 \tag{7.2.180}$$

Therefore it comes:

$$\frac{1}{1-\dfrac{\mathrm{i}}{2}(z-\mathrm{i})}=1+\frac{\mathrm{i}}{2}(z-\mathrm{i})+\left(\frac{\mathrm{i}}{2}(z-\mathrm{i})\right)^2+\left(\frac{\mathrm{i}}{2}(z-\mathrm{i})\right)^3+\ldots \tag{7.2.181}$$

Let us multiply both sides of this equality by $-\mathrm{i}/2$ and then divide them by $z-\mathrm{i}$ (the second term in the denominator of the original fraction) for obtain the left term:

$$\begin{aligned}\frac{1}{1-\dfrac{\mathrm{i}}{2}(z-\mathrm{i})}\frac{-\mathrm{i}}{2}\frac{1}{z-\mathrm{i}}&=\frac{-\mathrm{i}}{2-\mathrm{i}(z-\mathrm{i})}\frac{\mathrm{i}}{\mathrm{i}}\frac{1}{z-\mathrm{i}}=\frac{1}{2\mathrm{i}+(z-\mathrm{i})}\frac{1}{(z-\mathrm{i})}\\&=\frac{1}{2\mathrm{i}z+2+z^2-2z\mathrm{i}-1}=\frac{1}{z^2+1}\end{aligned} \tag{7.2.182}$$

and for the right term:

$$-\frac{\mathrm{i}}{2}\frac{1}{z-\mathrm{i}}-\left(\frac{\mathrm{i}}{2}\right)^2-\left(\frac{\mathrm{i}}{2}\right)^3(z-\mathrm{i})-\left(\frac{\mathrm{i}}{2}\right)^4(z-\mathrm{i})^2-\ldots \tag{7.2.183}$$

Finally we have the following geometric series:

$$\frac{1}{z^2+1} = -\frac{\mathrm{i}}{2}\frac{1}{z-\mathrm{i}} - \left(\frac{\mathrm{i}}{2}\right)^2 - \left(\frac{\mathrm{i}}{2}\right)^3 (z-\mathrm{i}) - \left(\frac{\mathrm{i}}{2}\right)^4 (z-\mathrm{i})^2 - \ldots \qquad (7.2.184)$$

We see then on this Laurent series around i of the holomorphic function $f(z)$ that the following coefficient appears:

$$c_{-1} = -\frac{\mathrm{i}}{2}, c_0 = -\left(\frac{\mathrm{i}}{2}\right)^2, c_1 = -\left(\frac{\mathrm{i}}{2}\right)^3 \qquad (7.2.185)$$

and then we have with Maple™ 4.00b:

```
>plot3d(abs(-I/2*1/((re+I*im)-I)-(I/2)^2-(I/2)^3*(re-I*im)-
(I/2)^4*(re-I*im)^2-(I/2)^5*(re-I*im)^3),
re=-1.5..1.5,im=-1.5..1.5,view=[-2..2,-2..2,-1..2],
orientation=[-130,70],contours=50,style=PATCHCONTOUR,axes=frame,
grid=[100,100],numpoints=10000);
```

This gives the following figure:

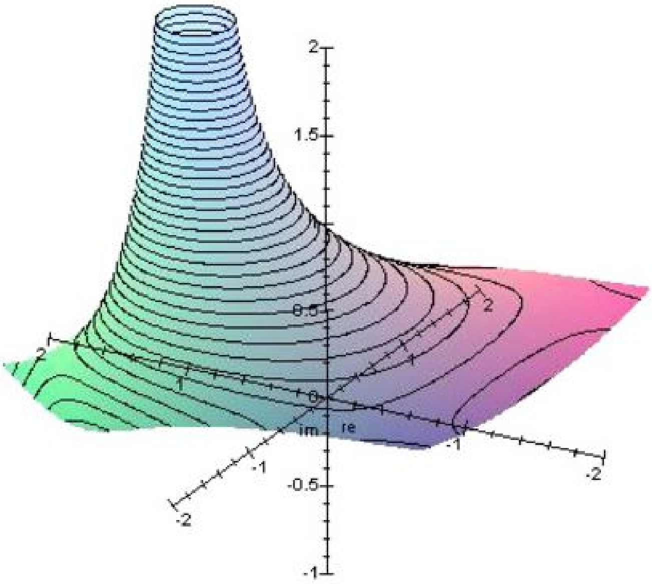

Figure 7.91: **Laurent series representation of $f(z)$ in Maple™ 4.00b**

where we see that the Laurent series allows us to express $f(z)$ in a neighbourhood close to the singularity i by taking five terms.

Ditto if we make the sum of the two Laurent series for the two singularities with seven terms:

```
>plot3d(abs(-I/2*1/((re+I*im)-I)-(I/2)^2-(I/2)^3*(re-I*im)-
(I/2)^4*(re-I*im)^2-(I/2)^5*(re-I*im)^3 -(I/2)^6*(re-I*im)^4
-(I/2)^7*(re-I*im)^5+I/2*1/((re+I*im)+I)+(I/2)^2+
(I/2)^3*(re+I*im)+(I/2)^4*(re+I*im)^2+(I/2)^5*(re+I*im)^3
+(I/2)^6*(re+I*im)^4 +(I/2)^7*(re+I*im)^5),re=-1.5..1.5,
im=-1.5..1.5, view=[-2..2,-2..2,-1..2],orientation=[130,70],
contours=50, style=PATCHCONTOUR, axes=frame,grid=[100,100],
numpoints=10000);
```

This gives the following graph:

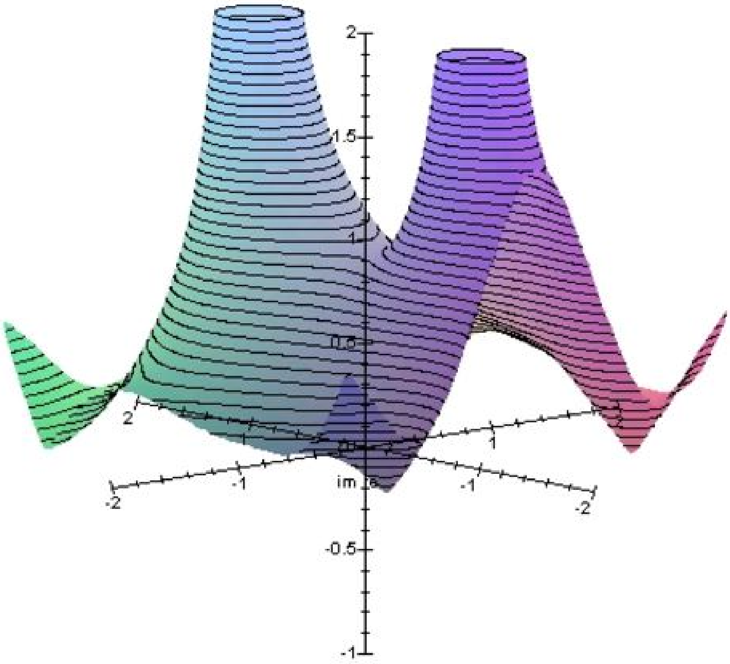

Figure 7.92: **Sum of the two Laurent series of $f(z)$ for both singularities in Maple™ 4.00b**

7.2.7 Singularities

We have seen just before that it was possible to calculate the path integral of a function, on condition of analyticity, on the outline of a singularity. Our goal will now be to enhance this approach.

We have already mentioned and highlighted in our previous proofs that the integrant in the "Cauchy's integral theorem" was of the form:

$$\frac{f(z)}{z-z_0} \tag{7.2.186}$$

where $f(z)$ is well defined in z_0.

The point $z-z_0$ is of course a singularity of $f(z)$ and it is not defined there.

As we saw during our proof of Laurent series, $f(z)$ can be expressed as a Laurent series in the form a positive power Laurent series in a convergence disk (or what remains the same, as a series of Laurent in a crown not centered on a singularity...) in the form:

$$\begin{aligned} f(z)=\frac{1}{z-z_0}&=\left(f(z_0)+\frac{1}{1!}f'(z_0)(z-z_0)^1+\frac{1}{2!}f''(z_0)(z-z_0)^2+\ldots\right)\\ &=\frac{f(z_0)}{z-z_0}+f'(z_0)+\frac{1}{2!}f'(z_0)(z-z_0)+\ldots \end{aligned} \tag{7.2.187}$$

Before continuing, it is customary in mathematics to define a small conventional vocabulary regarding this time the possible singularities of $f(z)$!

Let us first recall that we know, and that we have proved, that all information on the singularities of $f(z)$ are contained in the main part of the Laurent series (negative powers) defined on the crown surrounding z_0:

$$\sum_{n=1}^{+\infty} c_{-n}(z-z_0)^{-n} \tag{7.2.188}$$

The following classification focus on "isolated singularities", that is to say, a singular point where $f(z)$ is analytic everywhere in the neighbourhood of z_0 excepted on z_0 itself. This classification, as we will see permits us to distinguish three types of singular points, will be useful when developing the theory of residues further.

Definitions (#7.2.289):

D1. When the limit of the function $|f(z)|$ exists on z_0, we say that the singularity is a "removable singular point" or "apparent singularity".

For example:

$$f(z)=\frac{\sin(z)}{z} \tag{7.2.189}$$

does not seem to be defined on $z=z_0=0$ but we have a numerator having a Laurent series without negative powers (therefore a simple Taylor series). It then comes into by doing the Maclaurin series (that is to say the Taylor series on $z=z_0=0$...):

$$f(z)=\frac{\sin(z)}{z}=\frac{1}{z}\left(z-\frac{z^3}{3}+\ldots\right)=1-\frac{z^2}{3!}+\ldots \tag{7.2.190}$$

We then see that $f(z)$ finally has no term with negative power and therefore we have eliminated the singularity (or that it contains simply no singularities... which can easily be check with Maple™ 4.00b).

D2. When on z_0 the limit $|f(z)|$ does not exist we speak about "essential singularity".

For example, $z_0=0$ is an essential singularity for the function:

$$f(z)=e^{\frac{1}{z}} \tag{7.2.191}$$

Indeed, if z approaches zero coming from the positive real axis $\mathbb{R}_+$, the function diverges, more precisely, it tends to $+\infty$. If z comes from $\mathbb{R}_-$, the function tends to zero as illustrated by the following Maple™ 4.00b plot:

```
>plot3d(abs(exp(1/(re+I*im))),re=-5..5,im=-5..5,
view=[-3..3,-3..3,-0.5..3],orientation=[-130,70],contours=50,
style=PATCHCONTOUR,axes=frame,grid=[100,100],numpoints=10000)
>plot3d(abs(exp(1/(re+I*im))),re=-5..5,im=-5..5,
view=[-3..3,-3..3,-0.5..3],orientation=[-130,70],contours=50,
style=PATCHCONTOUR,axes=frame,grid=[100,100],numpoints=10000)
```

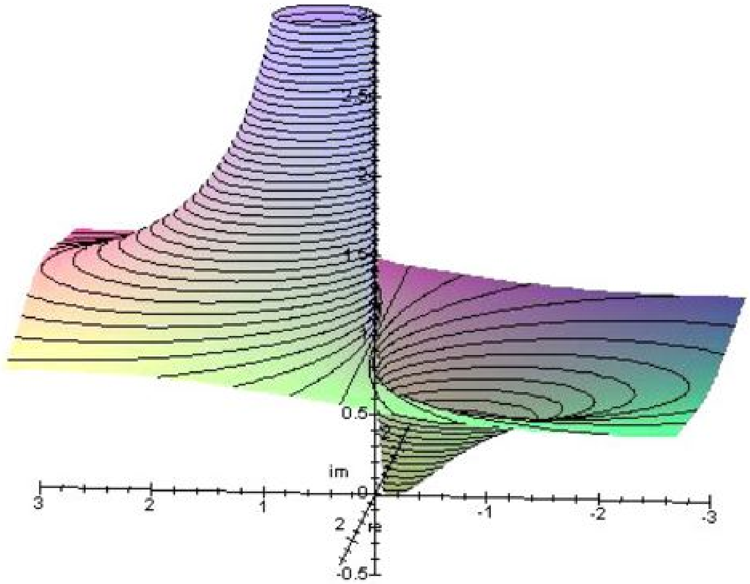

Figure 7.93: **Essential singularity example with $e^{1/z}$ in Maple™ 4.00b**

Indeed:

$$f(z)=e^{1/z}=\sum_{k=0}^{+\infty}\frac{\left(\dfrac{1}{z}\right)^2}{n!}=\sum_{k=0}^{+\infty}\frac{z^{-n}}{n!} \tag{7.2.192}$$

So an equivalent way of defining an essential singularity, is to say that there are an infinite number of terms with negative powers in the main part of the Laurent series.

D3. When on z_0 the limit of $|f(z)|$ is $+\infty$, we speak about a "pole".

This is the last category (as far as we know...) in which we can store a function that is not classifiable neither in the first nor in the second definition above.

So another equivalent way of defining a "pole", is to say that there is a finite number of terms with negative powers in the main part of the Laurent series. If the number of terms is k, then we speak of "pole of order k".

Remarks

R1. We sometimes say that an essential singularity is a " pole of order $+\infty$".

R2. A pole of order 1 is named a "simple pole". One of order 2 is named a "double pole" and so on...

If we come back on our example:

$$f(z)=\frac{1}{1+z^2} \tag{7.2.193}$$

We have proved previously that the Laurent series of this function in $z_0=\mathrm{i}$ was:

$$\frac{1}{z^2+1}=-\frac{\mathrm{i}}{2}\frac{1}{z-\mathrm{i}}-\left(\frac{\mathrm{i}}{2}\right)^2-\left(\frac{\mathrm{i}}{2}\right)^3(z-\mathrm{i})-\left(\frac{\mathrm{i}}{2}\right)^4(z-\mathrm{i})^2-\ldots \tag{7.2.194}$$

This function has therefore a trivial pole of order 1 on $z_0=\mathrm{i}$ and also on $z_0=-1$ because in this latter case this infinite series diverge to $+\infty$ and we can easily check this with the following Maple™ 17.00 command:

```
>sum(-(I*(1/2))^n*(-2*I)^(n-2), n = 0 .. infinity)
```

7.2.8 Residue Theorem

Consider a function $f(z)$ whose pole is of order less or equal to k.

Let us make it analytic:

$$\phi(z)=(z-z_0)^k f(z) \tag{7.2.195}$$

that is to say that we have take a function $f(z)$ that we have made analytic after elimination of the poles supposed in finite number - order - less than or equal to k on z_0.

This function $\phi(z)$ has therefore a Laurent series development in a disc center on z_0.

As we have prove it previously, we can therefore by using the following relation:

$$\phi^{(k)}(z_0)=\frac{\mathrm{d}^k\phi(z_0)}{\mathrm{d}z^k}=\frac{k!}{2\pi\mathrm{i}}\oint\frac{\phi(z)}{(z-z_0)^{k+1}}\mathrm{d}z \tag{7.2.196}$$

write:

$$\phi^{(k-1)}(z_0)=\frac{(k-1)!}{2\pi\mathrm{i}}\oint\frac{\phi(z)}{(z-z_0)^{k}}\mathrm{d}z \tag{7.2.197}$$

Using $f(z)$ under the integral it comes:

$$\phi^{(k-1)}(z_0)=\frac{(k-1)!}{2\pi\mathrm{i}}\oint f(z)\mathrm{d}z \tag{7.2.198}$$

You must deeply analyse this relation and understand that it link together the integral of a function having singularities with the value on one point of an analytical function having no more singularities!!!

This latter relation can be rewritten by rearranging terms:

$$\oint f(z)\mathrm{d}z=\frac{2\pi\mathrm{i}}{(k-1)!}\phi^{(k-1)}(z_0) \tag{7.2.199}$$

And by expressing $\phi^{(k)}(z_0)$ by using (this is authorized because this latter function is analytical) the fact that by definition:

$$\phi^{(k)}(z_0)=\frac{\mathrm{d}^k\phi(z_0)}{\mathrm{d}z^k} \tag{7.2.200}$$

We get obviously:

$$\oint f(z)\mathrm{d}z=\frac{2\pi\mathrm{i}}{(k-1)!}\frac{\mathrm{d}^{(k-1)}\phi(z_0)}{\mathrm{d}z^{(k-1)}} \tag{7.2.201}$$

Therefore by making $\phi(z)$ explicit again:

$$\boxed{\oint f(z)\mathrm{d}z=\frac{2\pi\mathrm{i}}{(k-1)!}\frac{\mathrm{d}^{(k-1)}}{\mathrm{d}z^{(k-1)}}\left[(z-z_0)^k f(z)\right]_{z=z_0}} \tag{7.2.202}$$

This latter relation is valid only for ONE isolated singularity (in case you forget!) and where k is equal at least to 1!

Mathematicians therefore define:

$$\boxed{\mathrm{Res}[f(z);z_0]=\lim_{z\rightarrow z_0}\frac{1}{(k-1)!}\frac{\mathrm{d}^{k-1}}{\mathrm{d}z^{k-1}}\left[(z-z_0)^k f(z)\right]_{z=z_0}} \tag{7.2.203}$$

as being the residue of the function $f(z)$ at the point being an isolated singularity of order k. Or respectively:

$$\mathrm{Res}[f(z);z_0]=\frac{1}{2\pi\mathrm{i}}\oint f(z)\mathrm{d}z \tag{7.2.204}$$

where the path integral is centered on z_0.

Now notice that the term on the right of the equality in the previous relation correspond to the coefficient c_{-1} of the Laurent series. Indeed:

$$c_n=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma}\frac{f(z')}{(z'-z_0)^{n+1}}\mathrm{d}z'\Rightarrow c_{-1}=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma}\frac{f(z')}{(z'-z_0)^{-1+1}}\mathrm{d}z'=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma}f(z')\mathrm{d}z' \tag{7.2.205}$$

Therefore:

$$\boxed{\mathrm{Res}[f(z);z_0]=c_{-1}} \tag{7.2.206}$$

Remark

Therefore it comes that on an isolated singularity that can be eliminated, the residue is null because as we saw it before, the path integral rounding a domain without singularity is equal to zero!

To resume, the relation:

$$\oint f(z)\mathrm{d}z=2\pi\mathrm{i}\mathrm{Res}[f(z);z_0]=2\pi\mathrm{i}c_{-1} \tag{7.2.207}$$

is very interesting for the physicist... because this is a very elegant way for him to calculate the path integral of a non analytic function $f(z)$ having a unique isolated singularity and this just by knowing the order of its poles!

For example if a function $f(z)$ has only a pole of order 1, we have therefore:

$$\oint f(z)\mathrm{d}z=\frac{2\pi\mathrm{i}}{(1-1!)}\frac{\mathrm{d}^{1-1}}{\mathrm{d}z^{1-1}}\left[(z-z_0)^1f(z)\right]_{z=z_0}=2\pi\mathrm{i}\lim_{z\to z_0}\left[(z-z_0)^1f(z)\right] \tag{7.2.208}$$

and we replace therefore z_0 by the desired value in the parenthesis $(z-z_0)$ and after we calculate the limit between brackets!

Now to go further, let us remind that the contour of the path integral:

$$\oint f(z)\mathrm{d}z \tag{7.2.209}$$

and the curvilinear path of the integral:

$$c_n=\frac{1}{2\pi\mathrm{i}}\int\limits_{\gamma}\frac{f(z')}{(z'-z_0)^{n+1}}\mathrm{d}z' \tag{7.2.210}$$

are in fact combined (identical) and the coefficients c_n do not depend on z! The only constraint on the path is that is closed and in an analytical domain centered on one point.

So if we have several isolated singularities, surrounded by connected curvilinear paths as shown below on the complex plane of a function having a pole of order 3 (i.e. three non-removable singularities z_0, z_1, z_2):

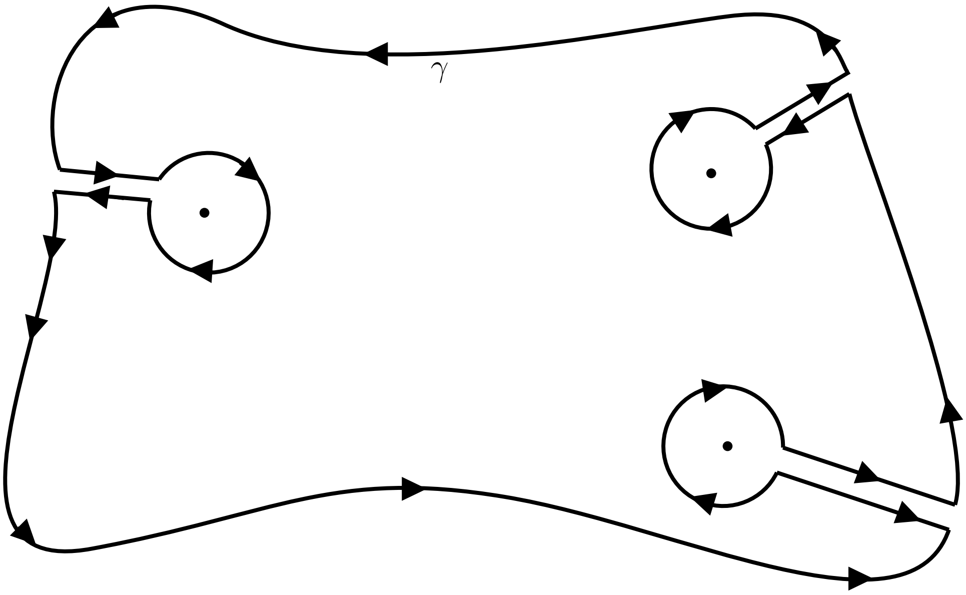

Figure 7.94: **Multiple isolated singularities surrounded by curvilinear paths**

then we have still only one closed curvilinear path but whose different isolated singularities are connected by cross which as we know: the paths that are opposed cancel themselves! And let us remind that the coefficients c_n are the same throughout on all the path since it is on an analytical domain.

We then have the generalized version of the residue theorem for a function f with n isolated singularities:

$$\boxed{\begin{gathered}\oint f(z)\mathrm{d}z=2\pi\mathrm{i}\sum_{i=1}^{n}\text{Res}\left[f(z);z_i\right]\\ \text{Res}\left[f(z);z_i\right]=\lim_{z\to z_0}\frac{1}{(k_i-1)!}\frac{\mathrm{d}^{k_i-1}}{\mathrm{d}z^{k_i-1}}\left[(z-z_i)^{k_i}f(z)\right]\end{gathered}} \tag{7.2.211}$$

with a rigorous approach that is specific to engineers ... who sometimes write this latter relation as following:

$$\oint f(z)\mathrm{d}z=2\pi\mathrm{i}\sum r_i \tag{7.2.212}$$

where r is therefore a residue. This is an important result in the field of solving differential equations associated with some inverse Laplace transforms (see section Functional Analysis page 2336). This intermediate result will give us the possibility to get an another one a little further of major importance for the section of Corpuscular Quantum Physics.

✍**Example:**

Let us take again our famous function:

$$f(z)=\frac{1}{1+z^2} \tag{7.2.213}$$

We know it has a pole of order 1 on $z_0=\mathrm{i}$ and a pole of order 1 on $z_0=-\mathrm{i}$. So if we take this time Laurent series with a path that surrounds the two singularities (and not only one) then we have a function with a pole of order 2.

It comes then for this particular case:

$$\oint f(z)\mathrm{d}z=2\pi\mathrm{i}\sum_{i=1}^{n}\text{Res}\left[f(z);z_i\right] \tag{7.2.214}$$

with n being equal to 2.

Then we have:

$$\begin{aligned}\text{Res}\left[f(z);z_1\right]=\text{Res}\left[f(z);\mathrm{i}\right]&=\lim_{z\to z_1}\frac{1}{(k_1-1)!}\frac{\mathrm{d}^{k_1-1}}{\mathrm{d}z^{k_1-1}}\left[(z-z_1)^{k_1}f(z)\right]\\&=\lim_{z\to\mathrm{i}}\frac{1}{(1-1)!}\frac{\mathrm{d}^{1-1}}{\mathrm{d}z^{1-1}}\left[(z-\mathrm{i})^1\frac{1}{z^2+1}\right]=\lim_{z\to\mathrm{i}}\left[(z-\mathrm{i})\frac{1}{(z+\mathrm{i})(z-\mathrm{i})}\right]\\&=\lim_{z\to\mathrm{i}}\frac{1}{z+\mathrm{i}}=-\frac{1}{2}\mathrm{i}\end{aligned} \tag{7.2.215}$$

and:

$$\begin{aligned}\text{Res}\left[f(z);z_2\right]=\text{Res}\left[f(z);-\mathrm{i}\right]&=\lim_{z\to z_2}\frac{1}{(k_2-1)!}\frac{\mathrm{d}^{k_2-1}}{\mathrm{d}z^{k_2-1}}\left[(z-z_2)^{k_2}f(z)\right]\\&=\lim_{z\to-\mathrm{i}}\frac{1}{(1-1)!}\frac{\mathrm{d}^{1-1}}{\mathrm{d}z^{1-1}}\left[(z-(-\mathrm{i}))^1\frac{1}{z^2+1}\right]\\&=\lim_{z\to-\mathrm{i}}\left[(z+\mathrm{i})\frac{1}{(z+\mathrm{i})(z-\mathrm{i})}\right]\\&=\lim_{z\to-\mathrm{i}}\frac{1}{z-\mathrm{i}}=\frac{1}{2}\mathrm{i}\end{aligned}\tag{7.2.216}$$

We can easily check this with Maple™ 4.00b:

```
>readlib(singular):
>singular(1/(1+z^2),z);
>readlib(residue):
>residue(1/(1+z^2),z=-I);
>residue(1/(1+z^2),z=I);
```

and therefore:

$$\oint\frac{1}{1+z^2}\mathrm{d}z=2\pi\mathrm{i}\sum_{i=1}^{2}\text{Res}\left[f(z);z_i\right]=0\tag{7.2.217}$$

In fact in this case, the residue theorem gives zero because the function has no poles to infinity which is true since in our example:

$$\lim_{z\to\pm\infty}|f(z)|\neq\infty\tag{7.2.218}$$

Physicists meanwhile say that... the force does make any work on this path ...!

7.2.8.1 Pole at infinity

We have say before that any function that did not have poles at infinity had therefore the sum of the residues of all the poles that are equal to zeros. This result is very important in physics and merits to be study!

It is almost trivial to recognize the number of poles... but to recognize the poles that are at infinity there are many times traps we can easily fall in.

Let us consider the expression $f(z)\mathrm{d}z$. If z is at the neighbourhood of the infinity then $1/z$ is near 0. Let us write:

$$t=\frac{1}{z}\tag{7.2.219}$$

Then we have:

$$f(z)\mathrm{d}z=-\frac{1}{t^2}f\left(\frac{1}{t}\right)\mathrm{d}t \tag{7.2.220}$$

Then the residue at infinity is such that:

$$\text{Res}\left[f(z);\infty\right]=\text{R}\left[g(t);0\right] \tag{7.2.221}$$

with:

$$g(t)=-\frac{1}{t^2}f\left(\frac{1}{t}\right) \tag{7.2.222}$$

Therefore with:

$$\boxed{\text{Res}\left[g(t);0\right]=\lim_{t\to 0}\frac{1}{(k-1)!}\frac{\mathrm{d}^{k-1}}{\mathrm{d}t^{k-1}}\left[(t-0)^k g(t)\right]=-\lim_{t\to 0}\frac{1}{(k-1)!}\frac{\mathrm{d}^{k-1}}{\mathrm{d}t^{k-1}}\left[t^k\frac{1}{t^2}f\left(\frac{1}{t}\right)\right]} \tag{7.2.223}$$

The latter relation we will be indispensable to us in the section of Corpuscular Quantum Physics Corpuscular to build the relativistic Sommerfeld model of hydrogenous atom because we will need to calculate a path integral with a pole.

Let's see an example with the function that accompanies us since the beginning of this section. That is to say:

$$f(z)=\frac{1}{z^2+1} \tag{7.2.224}$$

Therefore it comes:

$$g(t)=-\frac{1}{t^2}f\left(\frac{1}{t}\right)=-\frac{1}{t^2}\frac{t^2}{1+t^2}=-\frac{1}{1+t^2} \tag{7.2.225}$$

And we recognize immediately the initial function, in absolute value, and that has therefore no pole on 0. Therefore $f(z)$ has no pole at infinity.

7.3. Topology

TOPOLOGY is an extremely broad field of mathematics for which it is difficult to define precisely the object so the areas where it applies are varied (real line topology, graphs topology, differential topology, complex topology, symplectic topology, etc.).

We mainly make a distinction with:

- "General topology" that establishes the foundational aspects of topology and investigates properties of topological spaces and investigates concepts inherent to topological spaces. It includes point-set topology, which is the foundational topology used in all other branches (including topics like compactness and connectedness).
- "Algebraic topology" tries to measure degrees of connectivity using algebraic constructs such as homology and homotopy groups.
- "Differential topology" is the field dealing with differentiable functions on differentiable manifolds. It is closely related to differential geometry (see section of the same name in the chapter about Geometry page 2850) and together they make up the geometric theory of differentiable manifolds.
- "Geometric topology" primarily studies manifolds and their embeddings (placements) in other manifolds. A particularly active area is low dimensional topology, which studies manifolds of four or fewer dimensions. This includes knot theory, the study of mathematical knots.

Remark

A "manifold" is a higher dimensional analogue of a curve or a surface. A manifold of dimension n is a space, you can think of a collection of points, that locally looks like $\mathbb{R}^n$ for some integer n. All curves in the two dimensional plane that do not intersect locally look like part of a line. All smooth surfaces in $\mathbb{R}^3$, that is surfaces that do not have sharp kinks, edges (boundaries), or points all locally look like the two dimensional plane. Thus such surfaces are two dimensional manifolds. One should imagine being able to tear any small piece off the smooth surface, then being able to stretch it, push down any "hills" and push up any "valleys" to end up with a flat piece of the 2-plane. Therefore a manifold is a space that is locally Euclidean.

The picture to have in your mind when thinking about manifolds is the relation between a globe and a map. Small pieces of the globe can always be described by maps (pieces of the 2-plane). Moreover, the entire globe can be covered by a collection of maps: an atlas.

What we can say at first is that in its foundations Topology is very closely related to the set theory, the study of convergence of sequences and series, functional analysis, analysis complex, the differential and integral calculus, vector calculus and the geometry to mention only the most important cases that the reader can already found in this textbook.

The origin of Topology comes from the problems that laid to the progress of functional analysis in the rigorous study of continuous functions, their differentiability, their limits at a point (finite or note), the existence of extremums, etc. in higher-dimensional spaces (in fact, implicitly, the goal for topology is to create tools that easily allow to study the properties of functions in all dimensions). All these concepts, needed a rigorous mathematical definition of the intuitive idea of proximity, especially when doing operations on such functions.

We will try in this section to identify the basis of the structures that allow us to speak about limits and continuity and this only for curiosity as consultants in R&D and financial engineering we never saw a business application where the subjects below are absolutely necessary to develop a new business or solve a problem.

The majority of examples that we will take in this section will be in $\mathbb{R}$ (the $\mathbb{R}$ straight line to be more exact...) because it is the most used one by the engineers (and most of times the only one!) and the one we will have to use for the sections on Graph Theory, Statistics, Differential and Integral Calculus and also on Fractals. When we restrict our study of Topology on $\mathbb{R}$ we then speak of "Real Analysis".

7.3.1 General Topology

General topology is the branch of topology dealing with the basic set-theoretic definitions and constructions used in topology. It is the foundation of most other branches of topology, including differential topology, geometric topology, and algebraic topology.

The fundamental concepts in point-set topology are "continuity", "compactness", and "connectedness".

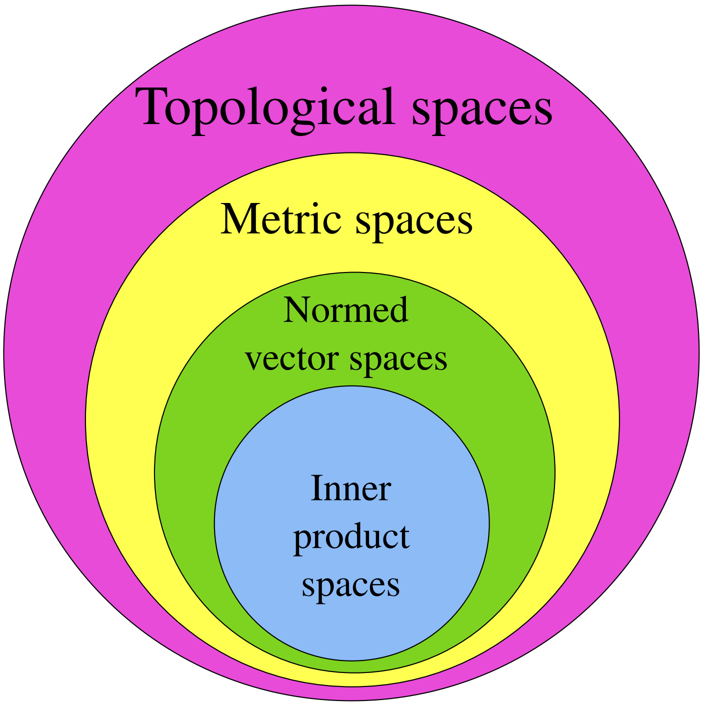
- Continuous functions take nearby points to nearby points.
- Compact sets are those that can be covered by finitely many sets of arbitrarily small size.
- Connected sets are sets that cannot be divided into two pieces that are far apart.

The words nearby, arbitrarily small, and far apart can all be made precise by using open sets. If we change the definition of open set, we change what continuous functions, compact sets, and connected sets are. Each choice of definition for open set is named a "topology". A set with a topology is named a "topological space".

"Metric spaces" are an important class of topological spaces where distances can be assigned a number named a "metric". Having a metric simplifies many proofs, and many of the most common topological spaces are metric spaces.

An "inner product" (see section Vector Calculus page 1829) induces a "norm" (see section Vector Calculus page 1818) and the norm induces a metric space.

Therefore we understand better what we will study in this section that can be summarized by the following figure:



7.3.1.1 Topological Spaces

Topological spaces form the conceptual foundation on which the concepts of limit, continuity or equivalence are defined.

The framework is general enough to be applied in many different situations: finite sets, discrete sets, geometry spaces, n dimensional numerical spaces and most complex functional areas. These concepts appear in almost all branches of mathematics, they are therefore central to the modern view of mathematics.

Definition (#7.3.290): Consider a non-empty set X (the length of a plastic ruler for example). A "topology $\mathcal{T}$" or "topological space $(x,\mathcal{T})$" on X is a family $\mathcal{T}$ of parts of X (of length of our rule...) named "open V" (as the open intervals seen in the section of Functional Analysis) such that the following axioms are true:

A1. The empty set $\varnothing$ and X are considered as open V and must belong to the family of the topology $\mathcal{T}$ (these only both open sets define what we name the "trivial topology" that is the most minimal one satisfying all the axioms):

$$\varnothing \in \mathcal{T} \quad \text{and} \quad X \in \mathcal{T} \tag{7.3.1}$$

In other words, if we imagine our plastic ruler, the measure zero (strictly speaking: the empty set) must belong to the topology defined on the ruler and the ruler itself (seen as a subset).

A2. Any finite intersection of open of $\mathcal{T}$ will be an open of $\mathcal{T}$:

$$V_1, V_2, \ldots, V_n \in \mathcal{T} \quad \text{implies} \quad \bigcap_{i=1}^{n} V_i \in \mathcal{T} \tag{7.3.2}$$

A3. Any union of open of $\mathcal{T}$ will be an open of $\mathcal{T}$:

$$V_1, V_2, \ldots, V_n \in \mathcal{T} \quad \text{implies} \quad \bigcup_{i=1}^{n} V_i \in \mathcal{T} \tag{7.3.3}$$

Remarks

R1. Mathematicians frequently note by O the family of open sets and by F the family of closed sets. Convention we will not follow in this textbook.

R2. The close sets of a topology are complementary of open sets. Therefore, the family of close sets contains among other X and the empty set $\varnothing$...

R3. There is no difference between part and subset of a set.

A4. The couple $(X, \mathcal{T})$ is a "Hausdorff space" or "separate space" if moreover the property named "Hausdorff axiom" is verified:

$$\forall p, q \in X \quad \text{with} \quad p \neq q, \exists V_p, V_q \in F \quad \text{such that} \quad p \in V_p, q \in V_q \quad \text{and} \quad V_p \cap V_q = 0 \tag{7.3.4}$$

Remarks

R1. A well known example of topological space is $\mathbb{R}$ provided with the set F generated by the open intervals (by the union law), that is to say the intervals of the type $]a, b[$.

R2. We will see a very concrete and beautiful + nice application of Hausdorff spaces in our study of fractals in the chapter Theoretical Computing.

Definitions (#7.3.291):

D1. If we denote by (X, V) a topological space, V designating the open sets of X, a "base", in the topological sense, of (X, V) is a part B of V such that any open set of V is an union of open sets of B (this is the same idea as vector spaces but in fact applied to sets ... nothing bad and difficult! If you want an example see the section of Measure Theory).

D2. In topology a subset A of a topological space X is named "dense" (in X) if for every point x in X either belongs to A or is a limit point of A. Informally, for every point in X, the point is either in A or arbitrarily "close" to a member of A. For instance, every real number is either a rational number or has one arbitrarily close to it. Therefore $\mathbb{Q}$ is dense in $\mathbb{R}$.

7.3.2 Metric Space and Distance

Definition (#7.3.292): A "metric space" denoted by (X,d) or sometimes X_d (or even sometimes just X if the type of distance d cannot not be confused) is by definition a set X with provided with an application:

$$d : X \times X \to \mathbb{R} \tag{7.3.5}$$

named "distance". If the distance satisfies the following "metric axioms":

A1. Positivity:

$$\forall x \neq y \in X \quad d(x,y) \geq 0 \tag{7.3.6}$$

A2. Separation:

$$\forall x,y \in X \quad d(x,y) = 0 \Leftrightarrow x = y \tag{7.3.7}$$

A3. Triangular inequality:

$$\forall x,y,z \in X \quad d(x,z) \leq d(x,y) + d(y,z) \tag{7.3.8}$$

A4. Symmetry:

$$d(x,y) = d(y,x) \tag{7.3.9}$$

we say then that the distance is a "metric". If a distance respect all axioms above excepted the triangular inequality we say then that the distance is a "dissimilarity measure".

The triangle inequality is necessary to define a metric because it ensures that the distance between two points is never shorter than the distance between them via a third point. This property is essential for many of the important concepts in metric spaces, such as convergence and continuity.

Remarks

R1. Some readers will probably see immediately that some of these properties have already been seen in other sections of this textbook during our study of distances between functional points and during our study of norms (like the riangle inequality proved in the section of Vector Calculus at page 1828).

R2. Some authors omit the axiom A1 which is strictly correct as it trivially follows from A3.

The "distance function" of $\forall x,y \in X$ is thus usually denoted in the more possible sense in mathematics (at least as far as we know):

$$d_{\text{name/symbol of distance}}(x,y) \tag{7.3.10}$$

we will see three examples much more further below with a schema.

Definition (#7.3.293): If we do not impose the axiom A2, we say that d is a "semi-distance" on X and if we allow a semi-distance d to take the value $+\infty$, we prefer to say that d is a "gap".

Remarks

R1. If a distance d satisfies the property (named "strong triangle inequality" or "ultrametric inequality"):

$$\forall x,y,z \in X \quad d(x,y) \leq \max\{d(x,y),d(y,z)\} \tag{7.3.11}$$

that is more restrictive than the triangle inequality in some spaces, we say that d is "ultrametric".

An example of ultrametric distance is the family tree (...):

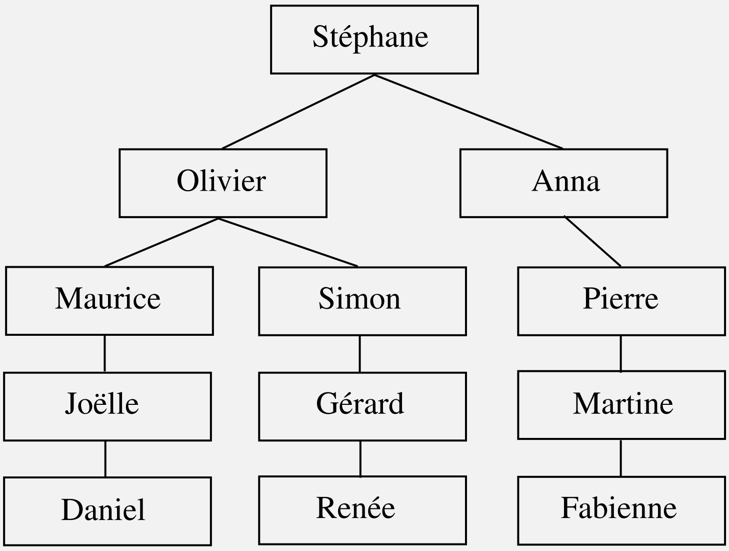


Figure 7.95: **Example of ultrametric distance with an orgchart**

We have the following distances:

$$\begin{aligned} d(\text{Daniel},\text{Stéphane}) &= 4\\ d(\text{Renée},\text{Stéphane}) &= 4\\ d(\text{Renée},\text{Fabienne}) &= 8\\ d(\text{Daniel},\text{Fabienne}) &= 8\\ d(\text{Daniel},\text{Renée}) &= 6 \end{aligned} \tag{7.3.12}$$

We note that the distances above do not add up, but we have by cons:

$$d(x,z) \leq \max\{d(x,y),d(y,z)\} \tag{7.3.13}$$

Therefore:

$$\begin{aligned} d(\text{Daniel},\text{Fabienne}) &\leq \max\{d(\text{Daniel},\text{Renée}),d(\text{Renée},\text{Fabienne})\}\\ 8 &\leq \max\{6,8\} \end{aligned} \tag{7.3.14}$$

Notice that the strong triangle inequality implies the triangular inequality:

$$d(x,z) = \max(d(x,y),d(y,z)) \leq d(x,y)+d(x,z) \tag{7.3.15}$$

because of the fact that the maximum of two numbers is less than or equal to their sum if both are greater or equal to zero.

R2. Let (X,d) be a metric space and consider $F=\varnothing$ a part of the set E. The metric space (F,δ) where δ denotes the restriction $d_{F\times F}$ of d is named "metric subspace" of (X,d) (we should check that the distance d is equivalent to the distance δ). In this case, we also say that F is provided with the distance induced by this of X. We therefore simply note d the induced distance.

Let us give now some examples:

✍**Examples:**

E1. If we take for X the plane, or the three-dimensional space of Euclidean geometry and a unit of length, the "distance" in the usual sense is a distance within the meaning of the 4 axioms mentioned above. In these spaces, the three points A,B,C satisfy as we have proved it in the section Vector Calculus:

$$d(A,B)\leq d(A,C)+d(C,B) \quad d(A,B)\geq |d(A,C)-d(C,B)| \tag{7.3.16}$$

with other inequality obtained by circular permutation of A,B,C. These inequalities are well known, for example between the side lengths of a triangle.

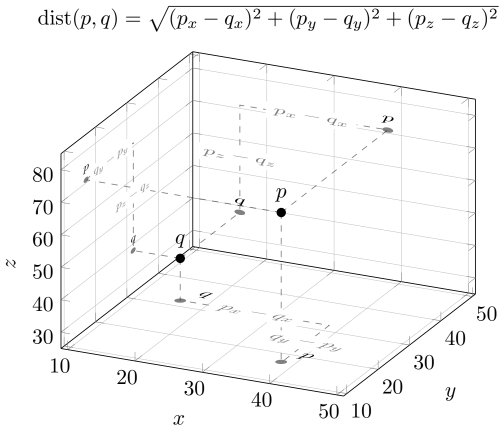
E2. If we take $X=\mathbb{R}^n$, $n\in\mathbb{N}\geq 1$ and that we equip $\mathbb{R}^n$ of an Euclidean vector space structure (and not non-Euclidean!) and we take two points:

$$x=(x_1,x_2,\ldots,x_n) \qquad y=(y_1,y_2,\ldots,y_n) \tag{7.3.17}$$

in $\mathbb{R}^n$, the distance is then given by (we have already proved this in the sections of Vector Calculus at page 1818):

$$d(x,y)=\sqrt{(x_1-y_1)^2+(x_2-y_2)^2+\ldots+(x_n-y_n)^2}=\sqrt{\sum_{i=1}^{n}(x_i-y_i)^2} \tag{7.3.18}$$

This distance is often represented in three dimensions as following:



This latter distance satisfies the four axioms of distance and we name it the "Euclidean distance" and is often denoted L_2. We can take (it is an interesting property for the general culture), any relation of the form:

$$d(x,y)=\sqrt[p]{(x_i-y_i)^p} \tag{7.3.19}$$

is also a distance in $\mathbb{R}^n$ (without proof) named "p-norm". In the particular case with $n=1$, we have of course:

$$d(x,y)=|x-y|=\max(x-y,y-x) \tag{7.3.20}$$

This is the usual distance on $\mathbb{R}$ and is often denoted L_2.

Mathematicians are even stronger by generalizing ever more (the proof has little interest for now in this textbook) the prior-previous relation (taking into account the definition of the distance) in the form:

$$\forall p\in[1,+\infty[\subset\mathbb{R}: \quad \delta_p(x,y)=\sqrt[p]{\sum_{i=1}^{n}(d(x,y))^n} \tag{7.3.21}$$

which is named "Hölder distance". Also sometimes denoted for $L_p:\mathbb{R}^n\mapsto\mathbb{R}$:

$$\boxed{\forall p\in[1,+\infty[\subset\mathbb{R}: \quad L_p(x)=||x||_p=\left(\sum_{i=1}^{n}|x_i|^p\right)^{1/p}} \tag{7.3.22}$$

Remark

Following the intervention of a reader we would like to point out that strictly speaking the above inclusion should be noted $[1,+\infty[\subset\overline{\mathbb{R}}$ where $\overline{\mathbb{R}}$ is the achieved line (also valid for precision for the Minkowski inequality below).

As for the triangle inequality given for recall by (see section Vector Calculus page 1828):

$$\vec{x},\vec{y}\in\mathbb{R}^3: \quad \|\vec{x}+\vec{y}\|\leq\|\vec{x}\|+\|\vec{y}\|\Leftrightarrow\sqrt[2]{\sum_{i=1}^{3}(x_i+y_i)^2}\leq\sqrt[2]{\sum_{i=1}^{3}x_i^2}+\sqrt[2]{\sum_{i=1}^{3}y_i^2} \tag{7.3.23}$$

the generalization, by the verification of the existence of the Hölder distance, gives us the true "Minkowski inequality":

$$\forall x,y\in\mathbb{R},p\in[1,+\infty[\subset\mathbb{R}: \quad \sqrt[p]{\sum_{i=1}^{n}(x_i+y_i)^p}\leq\sqrt[p]{\sum_{i=1}^{n}x_i^p}+\sqrt[p]{\sum_{i=1}^{n}y_i^p} \tag{7.3.24}$$

Let us continue with our examples:

✍**Examples:**

E3. If we take $X=\mathbb{C}$ we will consider the distance:

$$d(z,z')=|z-z'| \tag{7.3.25}$$

Therefore if $z=a+\mathrm{i}b=(a,b)$ and $z'=a'+\mathrm{i}b'=(a',b')$ we have the module that the same manner as norm in $\mathbb{R}^2$, forms a distance:

$$d(z,z')=\sqrt{(a-a')^2+(b-b')^2} \tag{7.3.26}$$

E4. Let us consider $E=\varnothing$ an arbitrary set. Let us write:

$$\delta(x,y)=1 \quad \text{if} \quad x\neq y \quad \text{and} \quad \delta(x,y)=0 \quad \text{if} \quad x=y \tag{7.3.27}$$

It is quite check that this distance satisfies the four axioms and that is furthermore an ultrametric distance. This distance is named "discreet distance" and the reader will notice that, by analogy, we choosed to express this distance by the Dirac symbol δ (this is not innocent !!) rather than the traditional d.

There are plenty of other distances used in practice that satisfies the four axioms of a distance. The technique used to measure distances depends on a particular situation you are working on. For instance, in some areas, the euclidean distance can be optimal and useful for computing distances. Other applications require a more sophisticated approach for calculating distances between points or observations like the cosine distance. As an image is many times worth one thousand words here is an illustration of the most well knows distances that respect the four axioms:

Figure 7.96: Common types of distances

We have already proven that the euclidean distance satisfies the four axioms at page 1818. We haven't done the proof that the four axioms are respected for all other distances visible in the figure above year in this textbook (the proof of the triangle inequality is quite boring to write most of the time).

💣Caution!!! Some computer scientists claim that the Sørensen–Dice distance and the Squared Euclidean distance are distances... but the latter doesn't respect the triangle equality as far as we know. Moreover there are also various definitions of the cosine distance and Pearson's distance and some of them doesn't respect the triangular equality. So be careful!

7.3.2.1 Equivalent Distances

Sometimes two different distances d and δ on the same set E are quite similar so that the related metric spaces $(E,d),(E,\delta)$ have the same properties for certain mathematical objects defined by d on one hand, and by δ on the hand. There are several concepts of equivalences for example first (before the others that require mathematical tools that we have not yet defined):

Definition (#7.3.294): Let d and δ be two distances on the same set E, d and δ are named "equivalent distances" if there are two real constants $c>0,C>0$ such that:

$$\forall x,y\in E:\quad c\cdot d(x,y)\leq\delta(x,y)\leq C\cdot d(x,y)\tag{7.3.28}$$

Therefore:

$$c\leq\frac{\delta(x,y)}{d(x,y)}\leq C\tag{7.3.29}$$

with $c\leq C$. We note this equivalence by:

$$d\sim\delta\tag{7.3.30}$$

The advantage of this definition is the following: if we have convergence for one of the metric, then we have convergence for the other too. More clearly:

$$d(x_n,x)\rightarrow 0\Leftrightarrow\delta(x_n,x)\rightarrow 0\tag{7.3.31}$$

verbatim:

$$x_n\overset{d}{\rightarrow}x\Leftrightarrow x_n\overset{\delta}{\rightarrow}x\tag{7.3.32}$$

7.3.2.2 Lipschitz Functions

With respect to the above definitions, we can now assign some additional properties to functions such as we had define in the section of Set Theory or Functional Analysis and analysed (in part...) in the section of Differential and Integral Calculus. The idea is also mainly to build a set of tools enabling the study of differential properties of non differentiable functions.

Let (E,d) and (F,δ) be metric spaces, and $f:E\rightarrow F$ a function. We define the following properties:

P1. We say that f is an "isometry" if (it is rather intuitive ...!):

$$\forall x,y\in E:\quad\delta[f(x),f(y)]=d(x,y)\tag{7.3.33}$$

✍**Exemple:**

On $]0,+\infty[$, let $\delta(x,y)=|\log(x)-\log(y)|$ and on $\mathbb{R}$ let $d(x,y)=|x-y|$. Then:

$$\begin{array}{ccc}(]0,+\infty[,\delta) & \longrightarrow & (\mathbb{R},d)\\ x & \mapsto & \log(x)\end{array}$$

is an isometry!

P2. If we take the usual distance, the L-Lipschitz or "Lipschits function of order L" is then defined on a given interval by:

$$\forall x,y\in E: \quad |f(x)-f(y)|\leq L|x-y| \tag{7.3.34}$$

that we can also write:

$$\forall x,y\in E: \quad \frac{|f(x)-f(y)|}{|x-y|}\leq L \tag{7.3.35}$$

or what remains the same: all line drawn between two arbitrary points of the graph must have a bounded and finite slope coefficient (derivative) between L and $-L$.

Any such L is referred to as a "Lipschitz constant" for the function f. As L can be define on intervals (not necessarily the whole domain of definition) smallest constant is sometimes named the "best Lipschitz constant".

Otherwise, one can equivalently define a function to be Lipschitz continuous if and only if there exists a constant L such that, for all $x\neq y$:

$$\frac{\mathrm{d}(f(x),f(y))}{\mathrm{d}(x,y)}\leq L \tag{7.3.36}$$

For real-valued functions of several real variables, this holds if and only if the absolute value of the slopes of all secant lines are bounded by k.

Therefore all Lipschitz must be continuous and any function f that has a bounded L value is more restrictive than just simply being continuous!

✍**Examples:**

E1. The function $f(x)=\sin(x)$ is 1-Lipschitz as the derivative of the cosine is between -1 and 1.

E2. The function $f(x)=x^2$ is locally Lipschitz as for any interval closed and finite interval we can find a bound L but is not globally Lipschitz as when $x\rightarrow\pm\infty$ then the derivative has also no bounds.

E3. The function $f(x)=|x|$ has no derivatives on $x=0$ in the ordinary sense. But its derivative in the Lipschitz sense on $x=0$ is given by the a closed interval denoted $\partial_L f(0)=[-1,1]$ given by the bound of L as the ordinary derivatives is less than or equal to L in absolute value!

This last example show us that the notion of a local minimum of a function $f(x)$ in the ordinary sense is generalized with Lipschitz condition. As we can now simply define the condition of local minimum of a non-smooth function $f(x)$ as:

$$0\in\partial_L f(x) \tag{7.3.37}$$

rather than in the ordinary sense (more restrictive):

$$f'=0 \tag{7.3.38}$$

Schematically for a Lipschitz continuous function, there is a double cone (shown in white) whose vertex can be translated along the graph, so that the graph always remains entirely outside the cone.

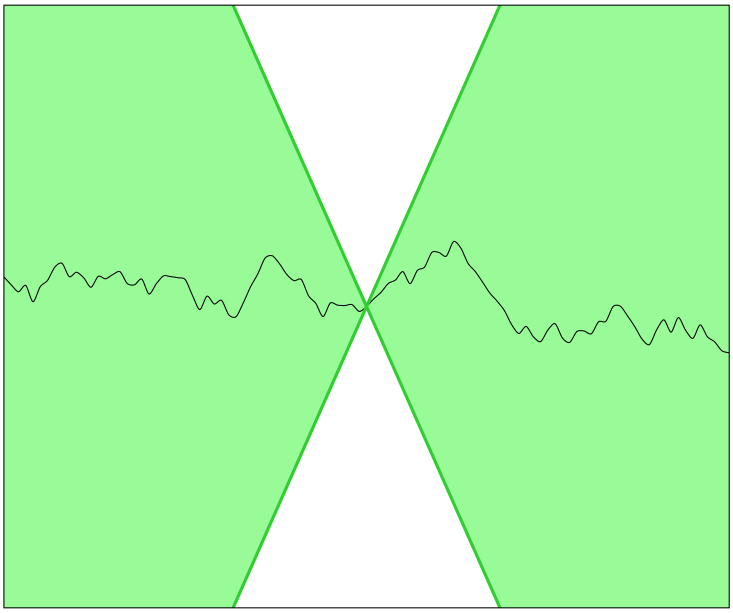

Figure 7.97: **Example of Lipschitz function (source: Wikipedia, author: Robert Zhang)**

Intuitively, a Lipschitz continuous function is therefore limited in how fast it can change: there exists a definite real number such that, for every pair of points on the graph of this function, the absolute value of the slope of the line connecting them is not greater than this real number; this bound is named a "Lipschitz constant" of the function (or "modulus of uniform continuity"). For instance, every function that has bounded first derivatives is Lipschitz.

P3. If $L=1$, we say that the function $f(x)$ is a "short map". If $-1<L<1$, we say that $f(x)$ is "strictly contracting".

P4. We say that two metric spaces are "isometric spaces" if there is a surjective isometry of one over the other (which is quite natural in geometry ...).

Remarks

R1. An isometry is always injective as by one of the axioms of distance:

$$f(x)=f(y)\Rightarrow \delta[f(x),f(y)]=0=d(u,v)\Rightarrow u=v \tag{7.3.39}$$

but in general it is not necessarily surjective (for a reminder of these concepts see page 406).

R2. If (E,d) and (F,δ) are isometric, of the point of view of the theory of metric spaces they are not discernible, as all their properties are the same, but their elements can be of very different nature (sequences in one and functions in the other).

7.3.2.3 Continuity and Uniform Continuity

As we already see it in the section of Functional Analysis (see page 2226), a continuous function is, roughly speaking, a function for which small changes in the input result in small changes in the output and that permits the analysis of limits. Otherwise, a function is said to be a discontinuous function. Formally it was defined by:

$$\forall x_0 \in E \forall \varepsilon > 0 \exists \delta > 0 \forall x \in E: \quad |x-x_0| < \delta \Rightarrow |f(x)-f(x_0)| < \varepsilon \tag{7.3.40}$$

In other words remember that this mean that a function is continuous if for every point x_0 in the domain E, we can make the images of that point ($f(x_0)$) and another point ($f(x)$) arbitrarily close (of a distance ε) if we move the other point (x) close enough (distance δ) to our given point.

Hence it is not continuous if:

$$\exists x_0 \in E \exists \varepsilon > 0 \forall \delta > 0 \exists x \in E: \quad |x-x_0| < \delta \Rightarrow |f(x)-f(x_0)| \geq \varepsilon \tag{7.3.41}$$

The previous definition is not so good for mathematicians as:

1. It makes usage of a special case of distance (the absolute value)
2. It defines continuity only for a given point x_0

It is therefore more common to generalize by writing:

$$\boxed{\forall x_0 \in E \forall \varepsilon > 0 \exists \lambda > 0 \forall x \in E: \quad d(x,x_0) < \lambda \Rightarrow \delta(f(x),f(x_0)) < \varepsilon} \tag{7.3.42}$$

Now let us state a more restrictive definition!

Definition (#7.3.295): A function $f(x)$ is "uniformly continuous" if it satisfies:

$$\boxed{\forall \varepsilon > 0 \exists \lambda > 0 \forall x_0, x \in E: \quad d(x_0,x) < \lambda \Rightarrow \delta[f(x),f(x_0)] \leq \varepsilon} \tag{7.3.43}$$

with $\lambda = \varepsilon / L$ and $L \neq 0$. In other words, if we can bring two points as close as we want in a space, so can we in the other way (which ensures somehow the derivation!).

Hence it is not uniformly continuous if:

$$\exists \varepsilon > 0 \forall \lambda > 0 \exists x_0, x \in E: \quad d(x_0,x) < \lambda \text{ and } \delta[f(x),f(x_0)] \geq \varepsilon \tag{7.3.44}$$

If we compare the two relations:

$$\forall x_0 \in E \forall \varepsilon > 0 \exists \lambda > 0 \forall x \in E: \quad d(x,x_0) < \lambda \Rightarrow \delta(f(x),f(x_0)) < \varepsilon \tag{7.3.45}$$

$$\forall \varepsilon > 0, \exists \lambda > 0, \forall x_0, x \in E: \quad d(x_0,x) < \lambda \Rightarrow \delta[f(x),f(x_0)] \geq \varepsilon \tag{7.3.46}$$

the only difference is the order of the quantifiers. Indeed, for something to be continuous, you can check "one x at a time", so for each x, you pick a ε and then find some $\varepsilon > 0$ that depends on both x and ε so that $|f(x)-f(x_0)| < \varepsilon$ if $|x-x_0| < \delta$. If we want uniform continuity, we need to pick first a ε, then find a δ which is good for ALL the x values we might have.

As the previous definition are not quite easy for everybody let us see the engineer version of these two definitions:

Definitions (#7.3.296):

D1. A function $f(x): E \rightarrow \mathbb{R}$ is "continuous" at a point $x_0 \in A$ if, for all $\varepsilon > 0$, there exists a $\delta > 0$ such that whenever $|x - x_0| < \delta$ (and $x \in E$) it follows that $|f(x) - f(x_0)| < \varepsilon$.

D2. A function $f(x): E \rightarrow \mathbb{R}$ is "uniformly continuous" on A if, for all $\varepsilon > 0$, there exists a $\delta > 0$ such that whenever $|x - x'| < \delta$ (and $(x, x') \in E$) it follows that $|f(x) - f(x')| < \varepsilon$.

Therefore we see better the difference: continuity is defined at a point x_0, whereas uniform continuity is defined on a set E. Roughly speaking, uniform continuity requires the existence of a single $\delta > 0$ that works for the whole set E, and not near the single point x_0.

The concept is illustrated below:

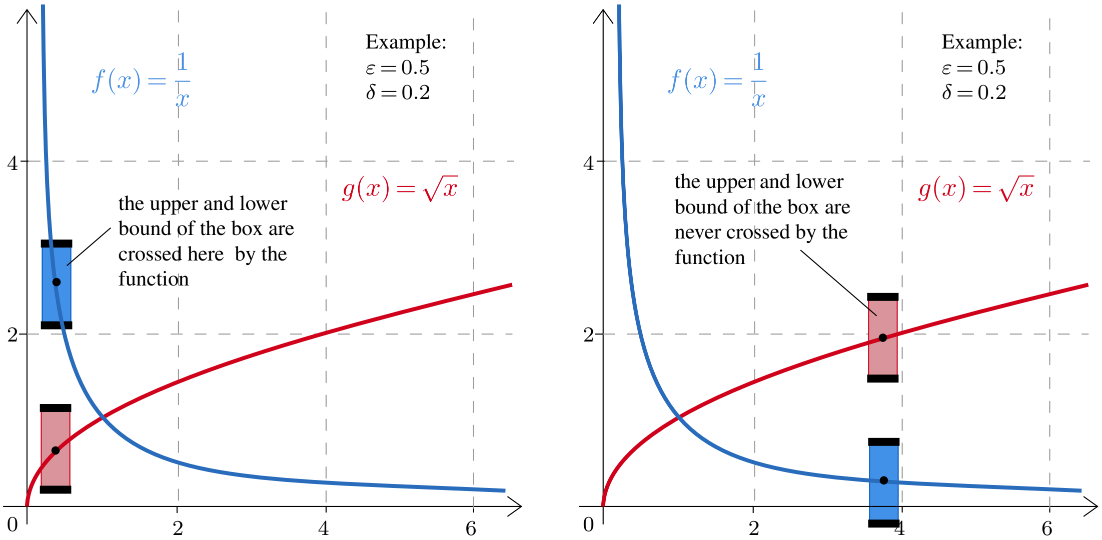

Figure 7.98: **Uniform continuity illustrated (source Wikpedia, author: Eskil Simon Kanne Wadsholt)**

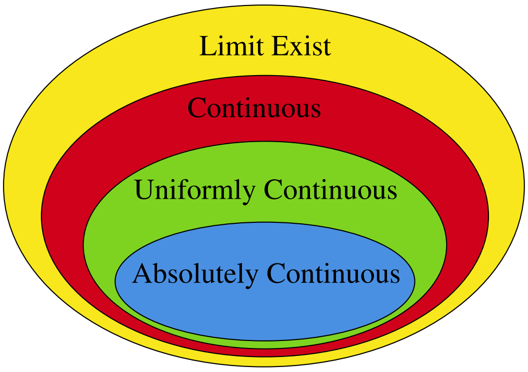
At some point the graph of $f(x) = 1/x$ will penetrate the top and/or bottom of a (here blue) window with height $2\varepsilon \in \mathbb{R}_{>0}$ and width $2\delta \in \mathbb{R}_{>0}$ while (f) ranging over an x-interval smaller than δ, as that window's center moves over the graph in the direction of $x = 0$. If there existed a window whereof top and/or bottom is never penetrated by this graph as the window moves over the graph in the direction of $x = 0$, then its width would be infinitesimally small, meaning that $f(x)$ is not uniformly continuous. The function $g(x) = \sqrt{x}$, on the other hand, is uniformly continuous.

From this definition we see that any uniformly continuous function is continuous but the reciprocity is not true (any uniformly continuous function is not necessarily continuous):



If the chosen distance is known (for example the absolute value for scalar functions such that $d = |\cdot|$ and $\delta = |\cdot|$) the previous definition notation changes obviously a little bit:

$$\forall \varepsilon > 0, \exists \delta > 0, \forall x_0, x \in E : \quad |x_0 - x| \leq \delta \Rightarrow |f(x_0) - f(x)| \leq \varepsilon \tag{7.3.47}$$

✍**Example:**

The function $f(x) = x^2$ is continuous but not uniformly continuous on the interval $E = [0, +\infty[$.

We prove first that our function $f(x)$ is continuous on E. Remember first that:

$$\forall x_0 \in E \forall \varepsilon > 0 \exists \lambda > 0 \forall x \in E : \quad d(x, x_0) < \lambda \Rightarrow \delta(f(x), f(x_0)) < \varepsilon \tag{7.3.48}$$

In our case we can therefore write and check that:

$$\forall \varepsilon > 0 \exists \delta > 0 \forall x_0, x \in E : \quad |x - x_0| < \delta \Rightarrow |x^2 - x_0^2| \leq \varepsilon \tag{7.3.49}$$

Let us choose $x_0 = a - 1$ with $a > 1$ and $\delta = \min(1, \varepsilon/2a)$ (note that δ depends on x_0 since a does). Choose $x \in S$. Assume $|x - x_0| < \delta$. Then $|x - x_0| < 1$ so $x < x_0 + 1$ so $x, x_0 < a$ so:

$$|x^2 - x_0^2| = (x + x_0)|x_0| \leq 2a|x - x_0| < 2a\delta \leq 2a\frac{\varepsilon}{2a} = \varepsilon \tag{7.3.50}$$

We prove now that $f(x)$ is not uniformly continuous on E, i.e.:

$$\exists \varepsilon > 0 \forall \delta > 0 \exists x_0 \in E \exists x \in S : \quad |x - x_0| < \delta \text{ and } |x^2 - x_0^2| \geq \varepsilon \tag{7.3.51}$$

Let $\varepsilon = 1$. Choose $\delta > 0$. Let $x_0 = 1/\delta$ and $x = x_0 + \delta/2$. Then $|x - x_0| = \delta/2 < \delta$ but:

$$|x^2 - x_0^2| = \left| \left(\frac{1}{\delta} + \frac{\delta}{2}\right)^2 - \left(\frac{1}{\delta}\right)^2 \right| = 1 + \frac{\delta^2}{4} > 1 = \varepsilon \tag{7.3.52}$$

as required.

7.3.3 Opened and Closed Set

Definition (#7.3.297): Consider a set E with a distance d. A subset U of E is named "open subset" if, for each element of U, there is a non-null distance r for which all the elements of E whose distance from this element is less than or equal to r, belong to U, which gives in mathematical language:

$$U \text{ open subset of } E \Leftrightarrow \forall x \in U, \exists r \in \mathbb{R}^{+} | \forall y \in E: \quad d(x,y) \leq r \Rightarrow y \in U \tag{7.3.53}$$

In topology, an open subset is then only an abstract concept generalizing the idea of an open interval in the real line.

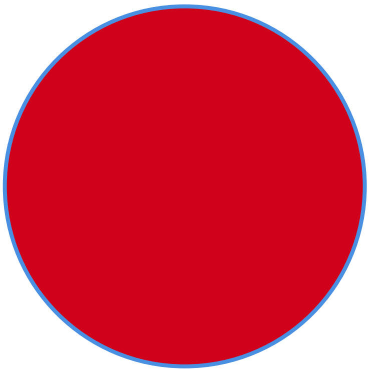
Remark

For recall, the symbol "|" means in this context: satisfies the property...

In practice, however, open sets are usually chosen to be similar to the open intervals of the real line. The notion of an open set provides a fundamental way to speak of nearness of points in a topological space, without explicitly having a concept of distance defined.

✍**Example:**

The points (x,y) satisfying $x^2+y^2=r^2$ are colored blue. The points (x,y) satisfying $x^2+y^2<r^2$ are colored red. The red points form an open subset of the plane $\mathbb{R}^2$. The blue points form a boundary set. The union of the red and blue points is a closed set.



This definition may perhaps seem complicated but in fact, its real meaning is simpler than it seems. In fact, according to this definition, an open set in a topological space is nothing more than a set of contiguous points and without borders.

The lack of border comes from the condition $r \neq 0$. Indeed, by reductio ad absurdum, if an open set U had an edge, then for each point on it (the edge) it would still be possible to find a point not belonging to U as close as we want from it. It follows that the distance r becomes necessary therefore zero.

Definitions (#7.3.298):

D1. A "closed subset" is an "open with edge".

D2. A "neighbourhood" of a point E is a subset of E containing an open subset containing this point.

The definition of an open set can be simplified by introducing an additional concept, that of "open ball":

7.3.3.1 Balls

Given x an element of E:

Definition (#7.3.299): An "open ball of center x and radius $r>0$" or "metric ball of radius r centered at x without border" is the subset of all the points of E whose the distance x is less than r, that we write in general:

$$_oB_x^r(E)=\{y\in E|d(x,y)<r\} \tag{7.3.54}$$

An open set can also be defined as a set for which it is possible to define an open ball at each point.

Typically in the real plane where d is the euclidean distance:

$$_oB_x^r(\mathbb{R}^2)=\left\{y\in\mathbb{R}^2|d(x,y)<r\right\} \tag{7.3.55}$$

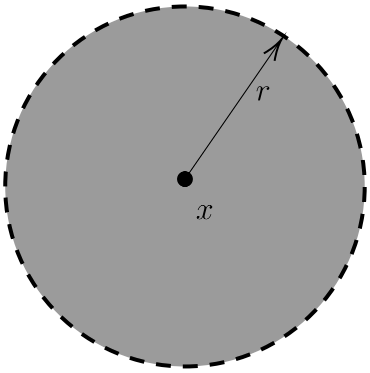


Figure 7.99: An open ball of radius r, centered at the point x

An open set can also be defined as a set for which it is possible to define an open ball at each point.

Remarks

R1. The open such defined, form what we name an "induced topology" by the distance d or also a "metric topology".

R2. We name an "open cover" U of E, a set of open of E whose union is equal to E. In other words: A collection of open sets that collectively cover another set.

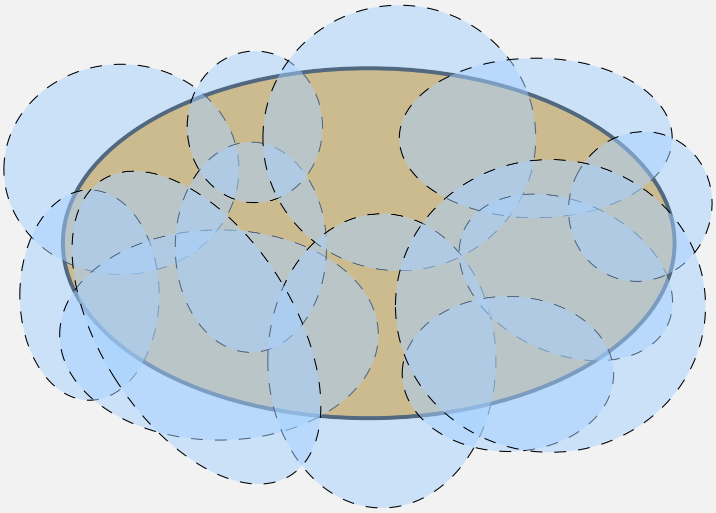
Formally, if:

$$C=\{U_\alpha : \alpha\in A\} \tag{7.3.56}$$

is an indexed family of open sets U_α, then C is a cover of X if:

$$E\subseteq\bigcup_{\alpha\in A}U_\alpha \tag{7.3.57}$$

Visually in a naive way this gives:



Open Cover

Definition (#7.3.300): A "closed ball" is similar to an open ball but differs in the sense that we include the elements located at a distance r from the center:

$$_fB_x^r(E)=\{y\in E|d(x,y)<r\} \tag{7.3.58}$$

Remark

For $0<r<r'$ the inclusions $_oB_x^r\subset B_x^r\subset B(x,r')$ are direct consequences of the definition of the open and closed ball.

✍**Example:**

The usual distance in $\mathbb{R}$ is given by $d(x,y)=|x-y|$. The balls are there simple intervals. For $x\in\mathbb{R}$ and $r\in\mathbb{R}_+^*$, we have:

$$_oB_x^r=]x-r,x+r[\quad\text{and}\quad {}_fB_x^r=[x-r,x+r] \tag{7.3.59}$$

Definition (#7.3.301): A "sphere" is given by:

$$S_x^r(E)=\{y\in E|d(x,y)=r\} \tag{7.3.60}$$

Remark

Since by definition $r>0$, open and closed balls are not empty because they contain at least their center. By cons, a sphere may be empty!

Example:

With $\mathbb{R}^n,\mathbb{C}^n$ we have seen in the previous examples we could set different distances. To distinguish them, we denote then by:

$$\begin{aligned} d_1(x,y)&=\sum_{i=1}^{n}|y_i-x_i|\\ d_2(x,y)&=\sqrt{\sum_{i=1}^{n}(y_i-x_i)^2}\\ d_\infty&=\max\{y_i-x_i,x_i-y_i\}\end{aligned}\tag{7.3.61}$$

So in $\mathbb{R}^2$ the closed balls with center O and of radius unit equivalent to the previous three formulations, have the following shapes (remember that $0<r\leq 1$ in this example):

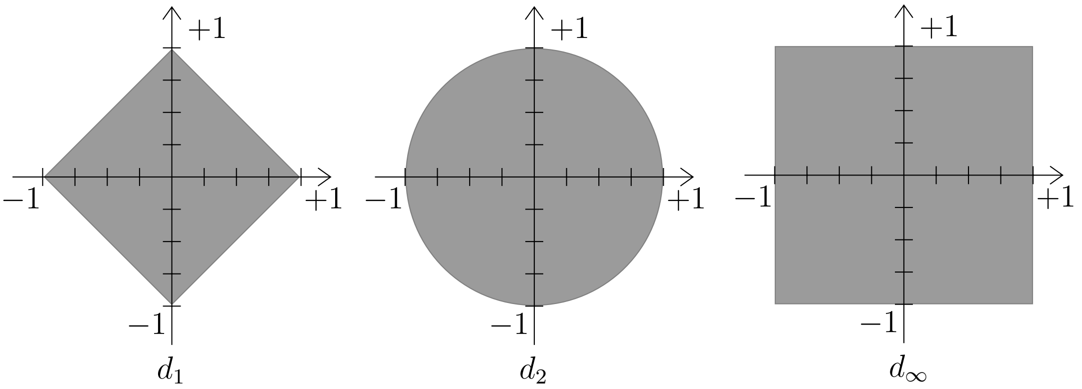


Figure 7.100: **Examples of closed balls of unit radius with different distances**

For example in statistics (see the section of the same name) we also use (among a lot of others) the Chi-2 distance given by:

$$d_{\chi^2}(x,y)=\sqrt{\sum_{i=1}^{n}\frac{(y_i-x_i)^2}{x_i}}\tag{7.3.62}$$

Or always in (multivariate) statistics (have a look to the Statistics section but also to the Industrial Engineering one) the "Mahalanobis distance":

$$d_M(x)=\sqrt{(\vec{x}-\vec{\mu})^T\Sigma^{-1}(\vec{x}-\vec{\mu})}\tag{7.3.63}$$

Remarks

The proof that the Mahalonobis distance is indeed a distance is straightforward. Indeed, without loss of generality, let us rewrite $x-\mu=\vec{x}$. Then:

$$d_M(x)=\sqrt{\vec{x}^T\Sigma^{-1}\vec{x}} \qquad (7.3.64)$$

But as we have proved it in the section Statistics at page 607, Σ is positive semi-definite, hence Σ^{-1} is most of time invertible (see section Statistics page 608). When it's invertible, all its eigenvalues are positive, then Σ^{-1} is also positive semi-definite (see section Linear Algebra page 1957). This implies that:

$$\vec{x}^T\Sigma^{-1}\vec{x}\geq 0 \qquad (7.3.65)$$

Therefore the Mahalonobis distance is indeed a distance (we should also prove that it respects the triangular inequality to show it is also a metric!). Another way to see it as engineer is just to consider that as $\Sigma^{-1}\vec{x}$ simply gives just another vector $\vec{y}$ such that:

$$d_M(x)=\sqrt{\vec{x}^T\Sigma^{-1}\vec{x}}=\sqrt{\vec{x}^T\vec{y}}=\sqrt{\vec{x}\circ\vec{y}} \qquad (7.3.66)$$

This it's just the euclidean distance between two different vectors!

For any other semi-positive definite matrix A other than the variance-covariance matrix we also define the "elliptic metric":

$$d_e(x)=\sqrt{\vec{x}^TA^{-1}\vec{x}} \qquad (7.3.67)$$

Or in the Error Correcting Codes section (see page 7167) we use the Hamming distance given by:

$$\forall x,y\in Q^n: \quad d_H(x,y)=\text{Card}\left\{i\in\mathbb{N}|x_i\neq y_i\right\}=\#\left\{i\in\mathbb{N}|x_i\neq y_i\right\} \qquad (7.3.68)$$

and so on...

7.3.3.2 Partitions

Now that we have defined the concepts of balls, we can finally (almost) rigorously define the concepts of open and closed intervals (which in a space of more than one dimension are named "partitions") that we have so often used in the section of Functional Analysis and Differential and Integral Calculus.

Definition (#7.3.302): Let (X,d) of a metric space. We say that a subset A of X is "bounded" if there is a closed ball ${}_fB^r_{r_0}(X)$ such that $A\subseteq_f B^r_{r_0}(X)$:

$$\forall x\in A, d(x_0,x)\leq r \qquad (7.3.69)$$

Given the previous note on balls inclusions, it is clear that we can replace the word "closed" by "open". Moreover the triangle inequality implies that the bounded character of A does not depend on the choice of x_0 (with a x_0' we simply need to replace r by $r'=r+d\left(x_0,x_0'\right)$).

✍**Example:**

The odd–even topology is the topology where $X = \mathbb{N}$ and:

$$P = \{\{2k-1, 2k\}, k \in \mathbb{N}\} \tag{7.3.70}$$

the unbounded partitions of radius $r < 1$.

Therefore we see that unless P is trivial, at least one set in P contains more than one point, and the elements of this set are topologically indistinguishable: the topology does not separate points!

Definitions (#7.3.303):

D1. Let X be a set and (Y, d) a metric space. If X is a set, we say that a function $f : X \mapsto Y$ is "bounded" if its image $f(X)$ is bounded (the case of the sine or cosine function, for example).

D2. Given (E, d) a metric space, and given A a non-empty subset of E. For any $u \in E$ we note $d(u, A)$ and name "distance u to A", the positive real number:

$$d(u, A) = \inf_{a \in A} d(u, a) = \inf \{d(u, a) | a \in A\} \tag{7.3.71}$$

We extend the concept by writing:

$$\forall u \in E: \quad d(u, \varnothing) = +\infty \tag{7.3.72}$$

If A and B are two parts (subsets) of E we have respectively (perhaps this is more understandable in this way for some readers...):

$$d(A, B) = \inf \{d(x, y) | x \in A, y \in B\} \tag{7.3.73}$$

The reader must take care here to interpret $d(A, B)$ as the infinimum of the distance between the sets A and B, because the distance between the parties does not always define a distance in the usual way on the part for example of $\mathcal{P}(\mathbb{R})$.

Indeed, if we take again our famous example:

$$A = \{0\} \quad \text{and} \quad B = \left\{\frac{1}{n+1}, n \in \mathbb{N}\right\} \tag{7.3.74}$$

we have $d(A, B) = 0$ when $n \to 0$ while $A \neq B$.

Remarks

R1. If the reader has well understood the definition of "parts" (and especially the previous example) he has probably noticed that it does not necessarily always exist a $a \in A$ such that $d(u, A) = d(u, a)$. Accordingly, we write:

$$\forall \varepsilon > 0, \exists \alpha = \alpha(\varepsilon) \in A: \quad d(u, A) \leq d(u, \alpha) < d(u, A) + \varepsilon \tag{7.3.75}$$

Moreover, if such an α exists, it is obviously not necessarily unique.

R2. It should be remembered that this distance also meets the four axioms of distances (we can give the proof on request)!

D3. Given (E,d) a metric space, and let A be a part (subset) of E. We name "adhesion" of A and denote by adh(A) the subset of E defined by:

$$\text{adh}(A)=\{u\in E|d(u,A)=0\} \tag{7.3.76}$$

For example, the adhesion of the part (subset) of rational numbers $\mathbb{Q}$ (part A) of $\mathbb{R}$ (the metric space E) is a subset of $\mathbb{R}$ itself since any real number is the limit of a rational.

Especially, since $\forall u\in A: \quad =+\infty$, we have $\text{adh}(\varnothing)=\varnothing$, and since $\forall u\in E: \quad d(u,E)=0$, we have $\text{adh}(E)=E$.

Remarks

R1. Any element of the set adh(A) is named "adherent point" of A.

R2. We say that a part A of E is a "closed part" if it is equal to its adherence.

R3. We say that a part A of E is an "open part" if its complementary relatively to E:

$$\complement_E A=A\setminus E \tag{7.3.77}$$

is closed.

It follows from the definitions that (without proof):

$$u\in\text{adh}(A)\Leftrightarrow\forall r>0: \quad {}_fB_u^r\cap A=\varnothing \tag{7.3.78}$$

and:

$$A\text{ is open }\Leftrightarrow\forall u\in A,\exists\rho>0: \quad {}_fB_u^r\subset A \tag{7.3.79}$$

with some properties (supposed as very obvious but we can give the proof on request):

P1. If $A\subset E$ and $B\subset E$ satisfies $A\subset B$, then we have:

$$\forall u\in E: \quad d(u,B)\leq d(u,A) \tag{7.3.80}$$

P2. For all $A\subset E$, any $u\in E$ we have:

$$d(u,A)=d(u,\text{adh}(A)) \tag{7.3.81}$$

The latter property has for corollary (obvious and therefore without proof excepted on request): If for any $u\in E$, we have $d(u,A)=d(u,B)$ and $A,B\neq\varnothing$, we then have:

$$\text{adh}(A)=\text{adh}(B) \tag{7.3.82}$$

7.3.3.3 Formal Ball

The concept of distance from a point to a set gives the possibility to extend the notions of ball and sphere see previously. We will see now the basis concepts of a "formal ball" also named "generalized ball".

D1. Given $A \neq \varnothing$ and given a $r > 0$. We name "generalized open ball" of center A of radius r, the following set:

$$_{o}B_{A}^{r} = \{y \in E | d(y, A) < r\} \tag{7.3.83}$$

and respectively "generalized closed ball":

$$_{f}B_{A}^{r} = \{y \in E | d(y, A) \leq r\} \tag{7.3.84}$$

and respectively a "generalized sphere":

$$S_{A}^{r} = \{y \in E | d(y, A) = r\} \tag{7.3.85}$$

D2. Given (E, d) a metric space and let A, B be two non-empty parts (subsets) of E. We denote by $g(A, B)$ and name "gap" of A to B, the real number greater than or equal to zero such that:

$$\begin{aligned} g(A,B) &= \inf_{a \in A} g(a,B) = \inf_{b \in B} g(b,A) = \inf_{a \in A} \inf_{b \in B} g(a,b) = \inf_{b \in A} \inf_{a \in B} g(a,b) \\ &= \inf\{d(a,b) | (a,b) \in A \times B\} \end{aligned} \tag{7.3.86}$$

Remark

The triangle inequality $g(A, B) \leq g(A, C) + g(C, B)$ is not valid in the context of gaps. To prove it, a single example that contradicts this inequality is sufficient.

✍**Example:**

In $\mathbb{R}$ let us take $A = \{0, 1\}, B = \{2, 3\}, C = \{1, 3\}$ then we have:

$$(g(A, B) = 1) > g(A, C) + g(C, B) = 0 + 0 = 0 \tag{7.3.87}$$

There is therefore a contradiction.

7.3.3.4 Diameter

Definition (#7.3.304): Given (E, d) a metric space and A a non-empty part (subset) of E. We denote $\text{diam}(A)$ and name "diameter" of A, the positive non-zero real number:

$$\text{diam}(A) = \sup\{d(a, b) | (a, b) \in A \times A\} \tag{7.3.88}$$

Every non-empty part (subset) A of a metric space satisfying $\text{diam} < +\infty$ will also be say "bounded".

Remark

We consider the empty set $\varnothing$ as bound set of diameter A.

If the whole metric space (E,d) is bounded, we say that the distance d is bounded. For example, the discrete distance is limited, the usual distance on $\mathbb{R}$ is not.

We also have the following properties (the first two are usually trivial, the third one comes from the definition of the diameter itself):

P1. $\text{diam}(A)=0\Leftrightarrow A=\{a\}$ or $A=\varnothing$

P2. $A\subset B\Rightarrow \text{diam}(A)\leq \text{diam}(B)$

P3. $\text{diam}({}_fB_x^r)\leq 2r, \text{diam}({}_oB_x^r)\leq 2r, \text{diam}(S_x^r)\leq 2r$

> Caution!!! Concerning the latter property, the reader must take the habit of thinking with the Euclidean distance. The first common pitfall is to think that the second diameter (that of the open ball) should be strictly less but that would be forgetting that the board has no thickness strictly speaking!

There is also often an understanding problem with $\text{diam}(S_x^r)\leq 2r$. To be convinced just take the discrete distance (that for two points that are not confused is equal to 1, otherwise 0). Thus, in a metric space where we take S_x^r with $r=1$, we have indeed $\text{diam}(S_x^1)\leq 1$ (that is an interesting case because almost completely counter-intuitive).

P4. $\text{diam}(A\cup B)\leq \text{diam}(A)+g(A,B)+\text{diam}(B)$

To be convinced, in $\mathbb{R}$ take $A=B$, then we have (trivial strict inferiority):

$$(\text{diam}(A\cup B)=\text{diam}(A))\leq \text{diam}(A)+g(A,B)+\text{diam}B) \tag{7.3.89}$$

P5. A is bounded if and only if: $\exists r>0,\exists x\in E:\quad A\subset_o B_x^r$

Definition (#7.3.305): We name "Hausdorff excess" or "Hausdorff distance" from X to Y:

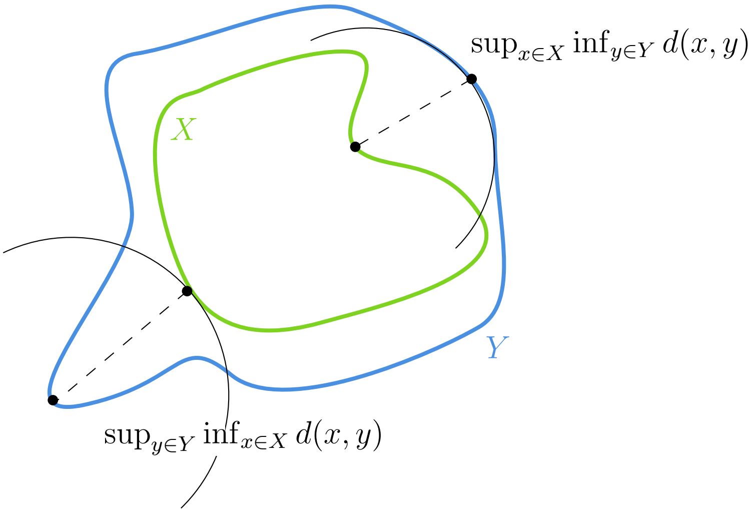
$$e(X,Y)=\sup\{d(x,Y)|x\in X\}=\max\{d(x,Y)|x\in X\} \tag{7.3.90}$$

that we found often in the literature with the more condensed notation:

$$e(X,Y)=d_H(X,Y) \tag{7.3.91}$$

or much more explicitly:

$$d_{\text{H}}(X,Y)=\max\left\{\sup_{x\in X}\inf_{y\in Y}d(x,y),\ \sup_{y\in Y}\inf_{x\in X}d(x,y)\right\} \tag{7.3.92}$$

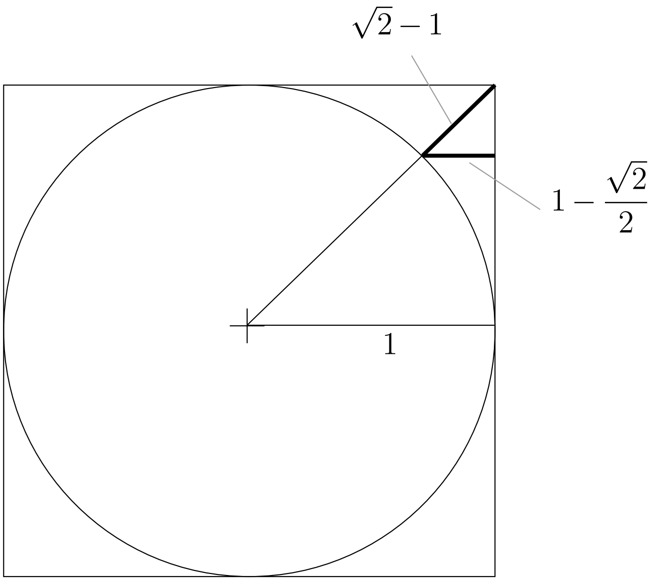


$\sup_{x\in X}\inf_{y\in Y} d(x,y)$
X
Y
$\sup_{y\in Y}\inf_{x\in X} d(x,y)$

Figure 7.101: Components of the calculation of d_H between X and Y (source: Wikipedia)

✍**Example:**

Let us take $X\subset\mathbb{R}^2$ as the unit radius circle centered at the origin and Y to the square circumscribing it. Elementary geometry concepts obviously leads to finding that the Hausdorff distance between the circle and the square is therefore:



$\sqrt{2}-1$
$1-\dfrac{\sqrt{2}}{2}$
1

Figure 7.102: High-school example of a Hausdorff distance in the plane

technically:

$$e(X,Y)=d_H(X,Y)=\sqrt{2}-1 \tag{7.3.93}$$

Remark

We have generally $e(X,Y)\neq e(Y,X)$ and these quantities may not be finite.

7.3.4 Varieties

We now introduce the "varieties". These are topological spaces that are "locally as $\mathbb{R}^2$" (our space for example ...), that is locally euclidean.

Definitions (#7.3.306):

D1. A "topological variety of dimension n" is a Hausdorff space M such that for every $p \in M$ there exists an open neighbourhood $U \subset M$ with $p \in U$, an open neighbourhood $U' \subset \mathbb{R}^n$ and a homeomorphism such that:

$$\varphi : U \mapsto U' \quad (7.3.94)$$

D2. A "homeomorphism" between two spaces is a continuous bijection whose inverse is also continuous.

D3. The pairs (U,φ) are named "maps", U being the "domain of the map" and φ the "coordinate application". Instead of "map" sometimes we say also "coordinate system".

Remark

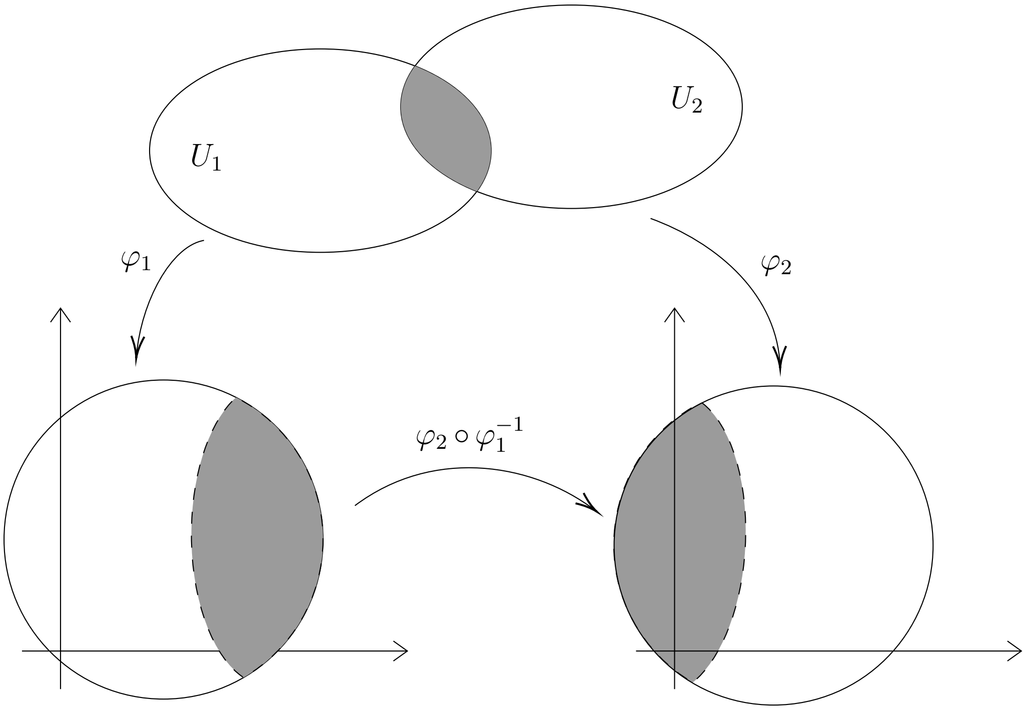
We will denote by $\dim(M)$ the dimension of a topological variety. Therefore:

$$\dim(M^n) = n \quad (7.3.95)$$

D4. Given M be a topological variety of dimension n. A family A of maps of M is named a "atlas" if for each $x \in M$, there exists a map $(U,\varphi) \in A$ such as $x \in U$.

If $(U_1,\varphi_1),(U_2,\varphi_2)$ are two maps of M such as $U_1 \cap U_2 \neq \varnothing$, then the application of map changes:

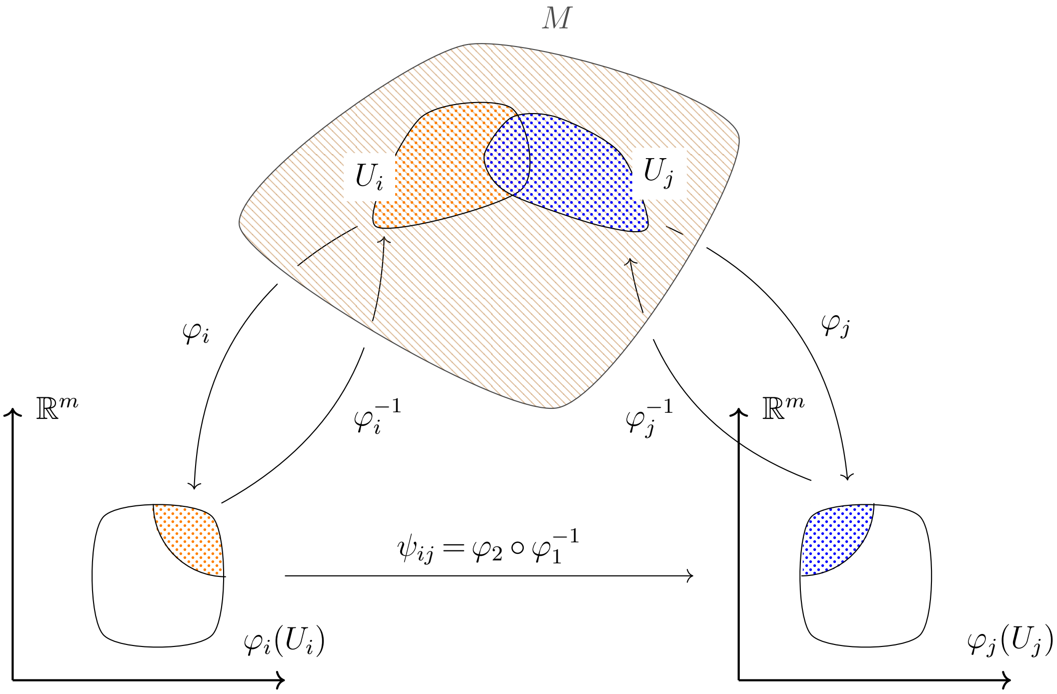
$$\varphi_2 \circ \varphi_1^{-1} : \varphi_1(U_1 \cap U_2) \rightarrow \varphi_2(U_1 \cap U_2) \quad (7.3.96)$$



U_1
U_2
φ_1
φ_2
$\varphi_2 \circ \varphi_1^{-1}$

Figure 7.103: A naive maps homeomorphisms

is obviously also a homeomorphism. We can find also the above figure sometimes in textbooks in a more explicit shape:



M
U_i
U_j
φ_i
φ_j
φ_i^{-1}
φ_j^{-1}
$\mathbb{R}^m$
$\mathbb{R}^m$
$\psi_{ij} = \varphi_2 \circ \varphi_1^{-1}$
$\varphi_i(U_i)$
$\varphi_j(U_j)$

Figure 7.104: A more complete maps homeomorphisms

More "geometrically" it looks like this:

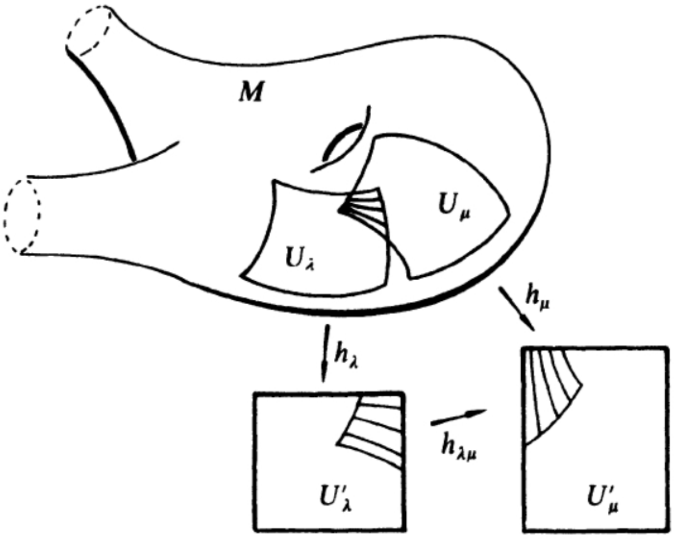


Figure 7.105: **Intuitive maps homeomorphism (source: ?)**

7.3.4.1 Subvariety

Definition (#7.3.307): A subset of a variety is itself a variety named a "subvariety".

✍**Example:**

A sphere of the three-dimensional Euclidean space $\mathbb{R}^3$ is an (algebraic) variety since it is defined by a polynomial equation. For example and is obviously smooth and locally euclidean:

$$x^2+y^2+z^2-1=0 \tag{7.3.97}$$

defines the sphere of radius 1 centered at the origin. Its intersection with the xy-plane is a circle given by the system of polynomial equations:

$$\begin{aligned} x^2+y^2+z^2-1&=0\\ z&=0 \end{aligned} \tag{7.3.98}$$

Hence the circle is itself an algebraic variety, and a subvariety of the sphere, and of the plane as well.

7.3.4.2 Surfaces Homeomorphism

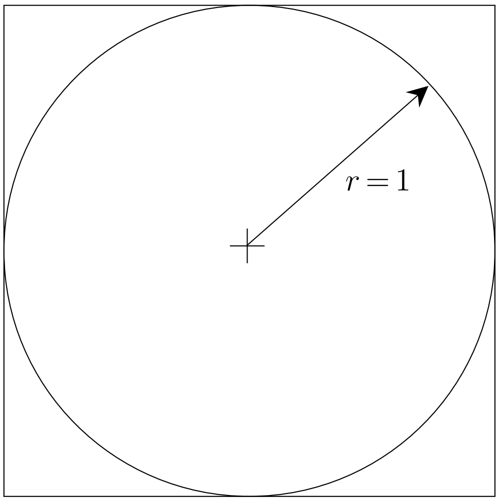
Definition (#7.3.308): In the mathematical field of topology, a "homeomorphism or "topological isomorphism" is a continuous function between topological spaces that has a continuous inverse function. Roughly speaking, a topological space is a geometric object, and the homeomorphism is a continuous stretching and bending of the object into a new shape. Thus, a square and a circle are homeomorphic to each other, but a sphere and a torus are not.

More formally, remember that an application $\varphi : X \mapsto Y$ between two topological spaces is named a homeomorphism if it has the following properties:

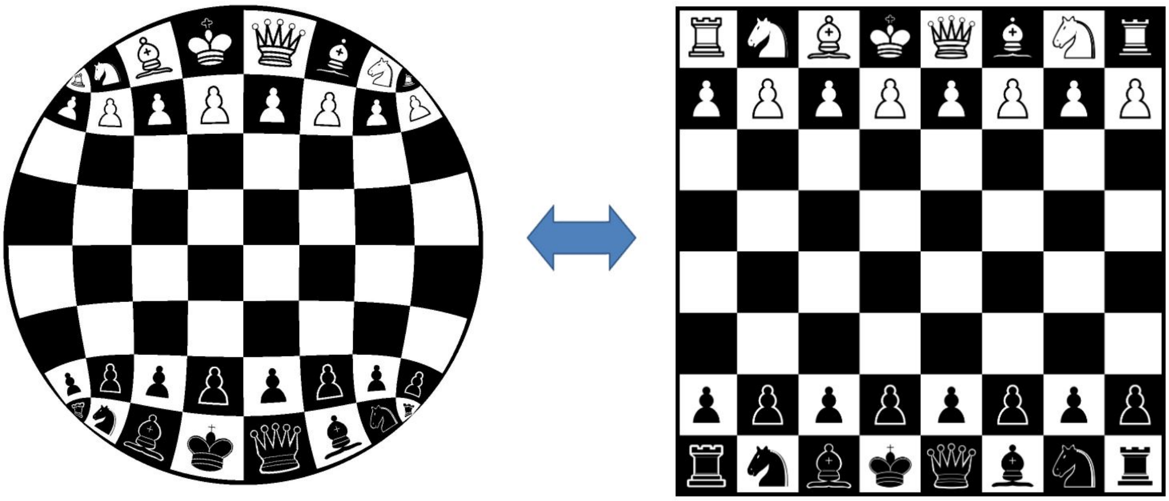
1. φ is a bijection (one-to-one and onto)
2. φ is continuous
3. The reciprocal function φ^{-1} is continuous

Can we say that a square (being a special map in $\mathbb{R}^2$) is homeomorph to a circle (being another special map in $\mathbb{R}^2$), or a torus to a cup of tea... If this is possible we must be able to find a closed form bijective expression between the two surfaces.

As the pure theoretical concepts are very not friendly in our point of view let us begin with a two dimensional special case. Let us show (prove) first that we can transform all interior points of square of side 1 into all interior points circle of radius 1. This is represented by the well known following figure:



Such mappings have particular interest in industrial design or just simply for communication purposes (Photoshop effects or Statistics charts deformation as we do many times in the `R` Software):



or for defishing fish eyes captors, picture or security mirrors:

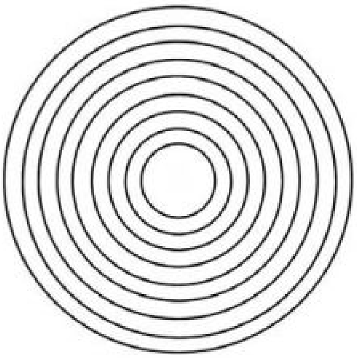
Recall that we defined unit disc as the set:

$$\mathcal{D}=\left\{(u,v)\in\mathbb{R}^2|u^2+v^2\leq 1\right\} \tag{7.3.99}$$

If we think of the unit disc as a continuum of concentric circles with radii growing from zero to one, we can parametrize the unit disc as the set:

$$\mathcal{D}=\left\{(u,v)\in\mathbb{R}^2|u^2+v^2=t^2,0\leq t\leq 1\right\} \tag{7.3.100}$$

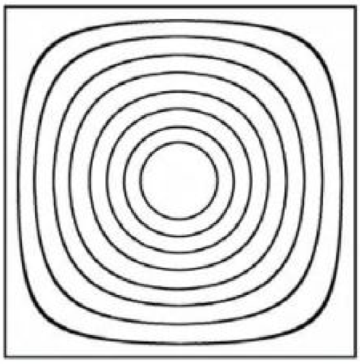
In doing so, we introduced a parameter t this is the distance of point (u,v) to the origin.



In analogy to the circular continuum of the unit disc, one can write the square region $[-1,1]\times[-1,1]$ as the set:

$$\mathcal{S}=\left\{(x,y)\in\mathbb{R}^2|x^2+y^2=t^2, 0\leq t\leq 1\right\} \tag{7.3.101}$$

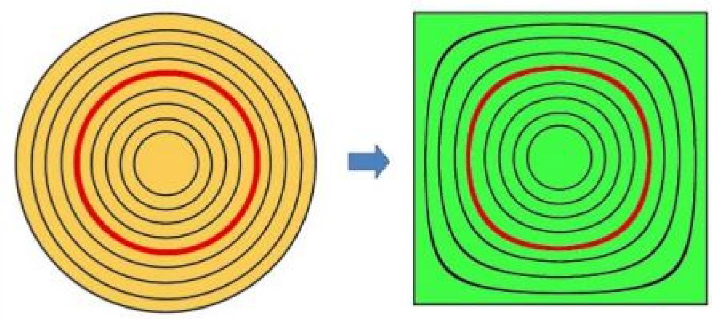
In other words, the square can be considered as a continuum of concentric shrunken FG-squircles (see section Analytical Geometry page 2812).



Topologists denote the proof that the interior points of two geometries are homeomorph in this special case using the following notation:

$$\mathring{\mathcal{D}}\sim\mathring{\mathcal{S}} \tag{7.3.102}$$

We will now show that $\mathring{\mathcal{D}}\mapsto\mathring{\mathcal{D}}$ as it is the most common case in practice in our point of view. That is to say:



We can establish a correspondence between the unit disc and the square region by mapping every circular contour in the interior of the disc to a squircular contour in the interior of the square. In other words, we map contour curves in the circular continuum of the disc to those in the squircular continuum of the square. This can be done by equating the parameter t of both sets to get the equation:

$$u^2+v^2=x^2+y^2-x^2y^2 \tag{7.3.103}$$

We name this equation the "squircularity condition" for mapping a circular disc to a square region.

It is easy to derive the FG-Squircular mapping by combining the squircularity condition:

$$t^2=u^2+v^2=x^2+y^2-x^2y^2 \tag{7.3.104}$$

That we can also write:

$$t^2=(t\cos(\theta))^2+(t\cos(\theta))^2=x^2+y^2-x^2y^2 \tag{7.3.105}$$

Using radial to cartesian coordinates (see section Vector Calculus page 1863):

$$t^2=\left(t\frac{x}{\sqrt{x^2+y^2}}\right)^2+\left(t\frac{y}{\sqrt{x^2+y^2}}\right)^2=x^2+y^2-x^2y^2 \tag{7.3.106}$$

Therefore by equivalence we get:

$$u=t\frac{x}{\sqrt{x^2+y^2}} \qquad v=t\frac{x}{\sqrt{x^2+y^2}} \tag{7.3.107}$$

After substitution of parameter t, we get:

$$\boxed{\begin{aligned}u&=\sqrt{x^2+y^2-x^2y^2}\frac{x}{\sqrt{x^2+y^2}}\\ v&=\sqrt{x^2+y^2-x^2y^2}\frac{x}{\sqrt{x^2+y^2}}\end{aligned}} \tag{7.3.108}$$

In other words, this is a radial mapping that converts circular contours on the disc to squircular contours on the square.

We shall now derive the inverse equations for the FG-Squircular mapping. But as it is boring to write in LaTeX and it is not used to much in practice we will omit the latter for the moment.

7.3.4.3 Differential Varieties

"Differential varieties" or "differentiable manifolds" are the basic objects of differential topology and differential geometry. These are varieties, "curved spaces" locally modelled on the Euclidean space of dimension n, on which it is possible to generalize a good part of the operations of differential and integral calculus.

A differential variety is therefore first defined by the data of a topological variety, a topological space locally homeomorphic to the space $\mathbb{R}^n$. Local homeomorphisms are named "maps" and define local coordinate systems. The differential structure is defined by requiring certain regularity properties of the transition maps between maps. This structure makes it possible, for example, to give a global definition of the notion of differentiable application, or of vector field with its integral curves.

On the other hand, unless the variety is provided with additional structures (such as a Riemannian metric), the calculations of derivatives of order 2, the notion of measurement of a part, do not admit of natural generalization.

Definitions (#7.3.309):

D1. A "differentiable variety" is a topological space M where the applications φ are of class $\mathcal{C}^{+\infty}$.

D2. A "diffeomorphism" is an application $\varphi : U \mapsto U'$ where U, U' are open domains of $\mathbb{R}^n$ and if φ is a homeomorphism and furthermore U, U' are differentiable!

> **Remark**
>
> Remember that "Differentiable" in this context will always mean of class $\mathcal{C}^{+\infty}$.

D3. Given a topological variety $M := M^n$ (to simplify the notations), two maps $(U_1, \varphi_1), (U_2, \varphi_2)$ of M are named compatible maps (more precisely: compatible of class $\mathcal{C}^{+\infty}$) if one of these two properties is satisfied:

P1. $U_1 \cap U_2 \neq \varnothing$ and the application $\varphi_2 \circ \varphi_1^{-1}$ of map changes is a diffeomorphism.

P2. $U_1 \cap U_2 = \varnothing$

An atlas A of M is differentiable if all maps of A are compatible between them.

> **Remarque**
>
> Given a differentiable atlas, it is sometimes necessary to complete it: we say that a map of M is compatible with a differentiable atlas if it is compatible with every map of A. An atlas of A is a "maximal atlas" if every compatible map of A belongs already to A. A maximal atlas is named a "differentiable structure".

7.4. Measure Theory

Caution! The level of abstraction and of motivation required for reading and understanding this section is quite high for engineers (target audience of this textbook for recall). The reader should be comfortable with the concepts seen in the section Set Theory as well as the one of Topology. We also apologize for the actual lack of figures.

THE measure, in the topological sense, will allow us to generalize the elementary notion of measure of a segment or area (in the Riemann sense, for example) and is inseparable from the new theory of integration that will build Lebesgue from the years to 11901-11902 (holocene calendar) and we will address here to build mathematical tools much more powerful than the simple Riemann integral (see section Differential and Integral Calculus page 1499) with practical and numerical example in MATLAB™.

The philosophers of science who developed measurement theory were largely concerned with epistemic questions like: we can't observe correlations between physical objects and real numbers, so how can the use of real numbers be justified in terms of things we can observe? Indeed, privileges a single unit of mass, involves real numbers in the facts of mass. Why is the latter bad?:

1. Real numbers are abstract and therefore causally inert
2. Real numbers don't fundamentally exist
3. Real numbers are constructed entities, and constructed entities can't be involved in fundamental facts

Measure Theory will also allow us to rigorously define the concept of "measurement" (no matter what is the measure) and so to return to important results of the study of probabilities (see section Probabilities page 450)! Indeed, we will see (we will define the vocabulary that follows just now further below) why (U, A, P) is[10] a "probability space" where A is in fact a "tribe" (also named "algebra") on U and P a measure on the measurable space (U, A).

---

[10] The notation of that tuple varies depending if we study topology, statistics or integral calculus.

7.4.1 Measurable Spaces

When in mathematics we calculate derivatives, primitives or simply count stuff, we carry implicitly a measure of an object or set of objects. Rigorously, mathematicians want to define how the measured thing can be structured, how to make a measurement of it and the properties resulting!

Measure theory is all about abstracting the idea of "size". What do we mean by size? Size is a number that we attribute to an object that obeys a specific, intuitive property: if we break the object apart, the sizes of the pieces should add up to the size of the whole.

There are many phenomena that follow this basic "size"-like idea including such phenomena as mass, length, and volume (and as we will see later, probability). For example, if we have a ball of clay and we split the ball of clay into two, then the masses of the two smaller balls of clay will add up to the mass of the original ball of clay.

Before we can discuss the "sizes" of objects and pieces of objects, we need a mathematical way to describe an object. Measure theory uses a set to denote the object that we are considering. For example, a set may represent a ball of clay. Given our object/set, we then need a way to describe how a set can be broken into pieces. This notion of "breaking an object into pieces" is described by the definition below.

Definitions (#7.4.310):

D1. Let E be a set, a "tribe" on E is a family $\mathcal{A}$ (this notation comes from the fact that many people speak of "**A**lgebra sets" instead of "tribe") of subsets of E satisfying the following axioms:

A1. $E \in \mathcal{A}$ (see examples below - E being one of the possible elements of $\mathcal{A}$).

A2. If A is a member of a tribe then:

$$A \in \mathcal{A} \Rightarrow A^c \in \mathcal{A} \tag{7.4.1}$$

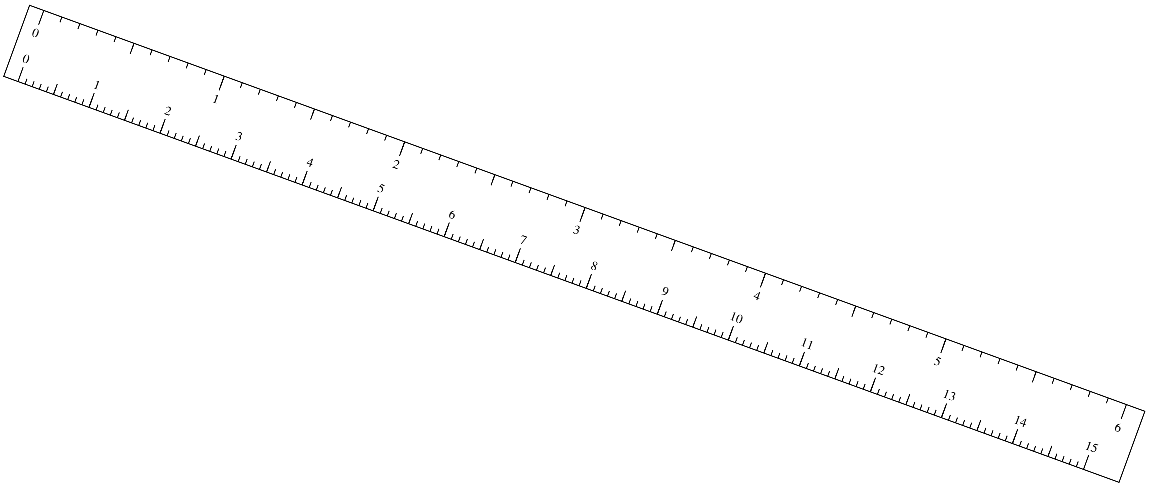
This means that $\mathcal{A}$ is "stable by transition to complementary". This axiom implies that the empty set is always an element of a tribe!

A3. For any sequence (A_n) of elements of $\mathcal{A}$ we have:

$$\bigcup_{i=1}^{n} A_n \in \mathcal{A} \tag{7.4.2}$$

We then say that $\mathcal{A}$ is then "stable by countable union" or also said to be "closed under set unions".

For example, the graduating from a simple ruler of measurement ... satisfies these three axioms!



Remarks

R1. We write $E \in \mathcal{A}$ because we consider with this notation E not anymore as a subset of $\mathcal{A}$ but as an element of $\mathcal{A}$!

R2. The uncountable cases are typical of topology, statistics or integral calculus!

D2. If in the third axiom we require that $\mathcal{A}$ is stable under finite (uncountable) union, i.e.:

$$\bigcup_{i=1}^{+\infty} A_n \in \mathcal{A} \tag{7.4.3}$$

then we impose the more general notion of "σ-algebra". Thus, a tribe is necessarily contained in an σ-algebra (but the opposite is not true just because the axiom is stronger) such that we can write:

$$\mathcal{A} \subseteq \sigma\text{-algebra}(\mathcal{A}) \tag{7.4.4}$$

With these properties in mind, another way to imagine this is to think of E as a ceramic plate that is cracked. The σ-algebra describes all the ways that the plate can fall apart along its "cracks" for a given type of crack.

Remark

In the field of probabilities, E is assimilated to the Universe of events and $\mathcal{A}$ to a family of events and we speak then of "probabilistic space" or simply of... "measurable space".

Okay, we have spent a while thinking about representing objects and pieces of an object. Now how do we assign each piece a "size"? This is where a measure comes into play. A measure is simply a function that assigns each piece of an object a size. As we discussed before, the sizes of two pieces of an object must add up to the size of the whole, which is exactly how a measure is defined!

D3. Given a set E and a σ-algebra on E, denoted $\mathcal{A}$, the function:

$$\mu:\mathcal{A}\rightarrow\mathbb{R} \tag{7.4.5}$$

is a "Lebesgue measure" if the following properties hold for μ (also denoted sometimes μ_L):

P1. Nonnegative: $\forall A\in\mathcal{A},\mu(A)\geq 0$

P2. Empty set has zero Lebesgue measure: $\mu(\emptyset)=0$

P3. The Lebesgue measure is invariant, i.e. $\mu(A)+\mu(A+c^{te})$

P4. Countable additivity: Given $A,B\in\mathcal{F}$ where $A\cap B=\emptyset$, then $\mu(A\cup B)=\mu(A)+\mu(B)$

The first part of the definition requires that a "size" (i.e. measure) cannot be negative. That's intuitive. The second part says that the "null piece" (i.e. nothing) has a size of zero. Finally, the third part says that the sum of the sizes of two pieces of an object must equal the size of the two pieces glued together.

D4. The pair $(E,\mathcal{A})$ is named "measurable space" and we say that the elements of $\mathcal{A}$ are "measurable sets".

D5. The tuple $(E,\mathcal{A},\mu)$ is named "measure space".

Therefore a measure space is simply the combination of a set (i.e. object), a σ-algebra (i.e. pieces of the object), and a measure μ (i.e. ways to describe the sizes of the pieces).

Intuitively, each element of the σ-algebra, represents a "piece" of the object. The first criteria in the definition above establishes a "null piece" (i.e. a piece of zero size) can be considered a piece of the object. The second criteria establishes the fact that if we break off a piece, A, of the object, then the remaining object A^c (the complement of A) is also a valid piece. Finally, the third criteria establishes the fact that if we glue a countable set of pieces together, the resultant piece is also a piece of the object.

✍**Examples:**

E1. Given $E=\{1,2\}$ a set of cardinal 2... The only two tribe $\mathcal{A}$ that satisfy the three axioms are:

$$\mathcal{A}_1=\{\varnothing,\{1\},\{2\},\{1,2\}\} \qquad \mathcal{A}_2=\{\varnothing,\{1,2\}\} \tag{7.4.6}$$

There are no other tribes for the set E as these two (the normal one, and the maximum one), because we must not forget that the union of each elements of the tribe must also be in the tribe (axiom A3), and also the complement of a member (axiom A2).

We also see from this example that if E is a set then $\{E,\varnothing\}$ is indeed a tribe!

E2. The set of parts of E, denoted $\mathcal{P}(E)$ is also a tribe (dixit previous example).

A tribe $\mathcal{A}$ is also "stable by the union of the finite complementaries". Indeed, if (A_n) is a sequence of elements of $\mathcal{A}$ we have (trivial when taking for example the previous first example):

$$\bigcup_n A_i^c \in \mathcal{A} \quad \text{and} \quad \left(\bigcup_n A_i^c\right)^c \in \mathcal{A} \tag{7.4.7}$$

A tribe is also "stable by finite intersection", that is to say (trivial also by taking the previous first example):

$$\bigcap_{i=1}^{+\infty} A_i \in \mathcal{A} \tag{7.4.8}$$

which brings to the property that a tribe is stable by finite unions and intersections. Especially, if we take two elements of a tribe $A, B \in \mathcal{A}$, then $A \setminus B \in \mathcal{A}$ with for recall (see section Set Theory page 398):

$$\boxed{A \setminus B = A \cap B^c} \tag{7.4.9}$$

Obviously it can be proven with a general theorem that tribes (i.e. algebras) are closed under set intersections, differences, and symmetric differences but we consider that latter as quite intuitive and not necessary in a book dedicated to engineers.

Remark

Most readers should probably easily see with the previous first example that if $(\mathcal{A}_i)_I$ is a family of tribes on E then $\bigcap_I \mathcal{A}_i$ is also a tribe (the verification is almost immediate).

Well it is nice to play with potatoes and sub-potatoes... and their complementary but let us continue...

Definition (#7.4.311): Given E a set and $\mathcal{B}$ a family of subsets of $\mathcal{P}(E)$ such that $\mathcal{B} \subset \mathcal{P}(E)$. We denote by definition:

$$\boxed{\sigma(\mathcal{B}) = \bigcap_{\mathcal{A} \in \mathcal{S}} \mathcal{A}} \tag{7.4.10}$$

the "generated tribe" by $\mathcal{B}$. Therefore $\sigma(\mathcal{B})$ is by definition the smallest tribe containing $\mathcal{B}$ (and by extension the smallest tribe of E).

Below are three small examples that gives the opportunity to check if what precedes has been well understood and that also gives the possibility to highlight important results for what will follow:

✍**Examples:**

E1. Given a set E and $A \subset E, A \neq E$ and also $\mathcal{B} = \{A\}$ then (when A is seen as a subset of E as given by the statement of a family of subsets!):

$$\sigma(\mathcal{B}) = \{\varnothing, E, A, A^c\} \tag{7.4.11}$$

E2. If $\mathcal{A}$ is a tribe on E then:

$$\sigma(\mathcal{A})=\mathcal{A} \tag{7.4.12}$$

E3. Given $E=\{1,2,3,4\}$ and $A=\{\{1,2\},3\}$ we then have (take care because now A is a family of parts (subsets) and not only a unique subset!) the following generated tribe:

$$\sigma(\mathcal{A})=\{\{\varnothing\},\{3\},\{4\},\{1,2\},\{3,4\},\{1,2,3\},\{1,2,4\},\{1,2,3,4\}\} \tag{7.4.13}$$

Rather than determining this tribe by seeking the smallest tribe $\mathcal{P}(E)$ containing A (which would be laborious) we play with the axioms defining a tribe to easily find it.

So therefore we find well in $\sigma(A)$ at least the obligatory empty set $\{\varnothing\}$ and also:

$$E=\{1,2,3,4\} \tag{7.4.14}$$

following the axiom A1 and:

$$E=\{\{1,2\},\{3\}\} \tag{7.4.15}$$

itself by the definition of $\sigma(A)$ and the complementaries of:

$$\{\{3\}^c=\{1,2,4\},\{1,2\}^c=\{3,4\},\{\{1,2\}\cup\{3\}\}^c=\{4\}\} \tag{7.4.16}$$

following the axiom A2 and also the unions:

$$\bigcup_i A_n=\{\{1,2\}\cup\{3\}=\{1,2,3\},\{1,2\}\cup\{1,2,3\}=\{1,2,3\},\ldots\} \tag{7.4.17}$$

following the axiom A3.

Definition (#7.4.312): Let E be a topological space (see section Topology page 2447). We denote by $\mathcal{B}(E)$ the tribe generated by the open sets of E. $\mathcal{B}(E)$ is named the "borelian tribe" of E. The elements of $\mathcal{B}(E)$ are named the "borelians" of E.

Remarks

R1. The notion of borelian tribe is especially interesting because it is necessary for the definition of "Lebesgue tribe" and afterwards to the "Lebesgue measure" that will lead us to define the famous "Lebesgue integral"!

R2. The tribe $\mathcal{B}(E)$ being stable by going to the complementary, it also contains all closed subsets.

R3. If E is a topological space with a finite basis, $\mathcal{B}(A)$ in generated by the opens of the basis.

✍**Example:**

If $\mathbb{R}$ designates the space provided of real numbers with the Euclidean topology (see section Topology page 2453), the family of open intervals with rational bounds is a "countable base" (given the bounds...) of $\mathbb{R}$ and therefore generates $\mathcal{B}(\mathbb{R})$. Same thing for $\mathbb{R}^d$ with for countable basis the family of open spaces with rational bounds.

Theorem 7.8. Let us now consider $\mathcal{S}$ a dense set (see section Topology page 2449) in $\mathbb{R}$. The following families generate $\mathcal{B}(\mathbb{R})$:

$$\{]-\infty,a[\,,a\in\mathcal{S}\}\quad\{]-\infty,a]\,,a\in\mathcal{S}\}\quad\{]a,+\infty[\,,a\in\mathcal{S}\}\quad\{[a,+\infty[\,,a\in\mathcal{S}\}\tag{7.4.18}$$

Proof 7.8.1. Given (the family of open subsets):

$$\mathcal{F}=\{]-\infty,a]\,,a\in\mathcal{S}\}\tag{7.4.19}$$

We have obviously:

$$\sigma(\mathcal{F})\subseteq\mathcal{B}(\mathbb{R})\tag{7.4.20}$$

Furthermore:

$$([a,+\infty[\cap]-\infty,b[)=[a,b[\text{ if }a<b\tag{7.4.21}$$

Therefore the intervals of the type $[a,b[$ with a and b in $\mathcal{S}$ also belongs to $\sigma(\mathcal{F})$. Therefore, if we generalize, with $x<y$, it exists a sequence (a_n) of elements of $\mathcal{S}$ decreasing to x and a sequence (b_n) of elements of $\mathcal{S}$ increasing to y such that:

$$]x,y[=\bigcup_n[a_b,b_n[\in\sigma(\mathcal{F})\tag{7.4.22}$$

which bring in the same way as $E\in\mathcal{A}$ that $\mathcal{B}(\mathbb{R})\subseteq\sigma(\mathcal{F})$. Other cases can be treated analogously.

■ Q.E.D.

Theorem 7.9. Given $(E,\mathcal{A})$ a measurable space and $A\subseteq E$ (and $A\in\mathcal{A}$) (where A is therefore considerate as a subset and non as an element!). The family $\{A\cap B|B\in\mathcal{A}\}$ is a tribe on A named "trace tribe" of $\mathcal{A}$ on A, that we will denote by $A\cap\mathcal{A}$. Furthermore, if $A\in\mathcal{A}$, the trace tribe is formed by the measurable elements contained in A.

Proof 7.9.1. We will do a proof by the example (... yes it is not a real proof...). For this we check the three points that define a tribe:

1. $A=(E\cap A)\Rightarrow A\in(A\cap\mathcal{A})$
2. Given $B\in\mathcal{A}$, $A\setminus(A\cap B)=A\setminus B=A\cap B^c=A\cap B^c$ and therefore $A\setminus(A\cap B)\in(A\cap\mathcal{A})$

✍**Example:**

Given $E=\{1,2,3\}$ then (a tribe among others - do not forget the stability by union!):

$$\mathcal{A}=\{\varnothing,\{1\},\{2\},\{3\},\{1,2\},\{1,3\},\{2,3\},\{1,2,3\}\} \tag{7.4.23}$$

Let us choose $A=\{1,2\},B=\{2,3\}$ (it is obvious that $\{A\cap B|B\in\mathcal{A}\}$ is a tribe on A). Then:

$$\begin{aligned}A\setminus(A\cap B)=\{1,2\}-(\{1,2\}\cap\{2,3\})=\{1,2\}-\{2\}&=\{1\}\\ A\setminus B=\{1,2\}-\{2,3\}&=\{1\}\\ A\cap B^c=\{1,2\}\cap\{2,3\}^c=\{1,2\}\cap\{1\}&=\{1\}\end{aligned} \tag{7.4.24}$$

and we have well $\{1\}\in A$ and also $A\in(A\cap\mathcal{A})$.

3. Given $(A\cap B_n)$ a sequence of elements of $A\cap\mathcal{A}\,(B_n\in\mathcal{A})$ then:

$$\bigcup_n(A\cap B_n)=A\cap\underbrace{\left(\bigcup_n B_n\right)}_{\in\mathcal{A}}\in A\cap\mathcal{A} \tag{7.4.25}$$

The last statement of the proposition will be supposed as obvious (if not, let us know!).

■ Q.E.D.

Given now E a set, $\mathcal{C}$ a family of subsets of E and $A\subseteq E$ non empty. We denote by $A\cap\mathcal{C}$, the trace $\mathcal{C}$ on A and $\sigma_A(A\cap\mathcal{C})$ the tribe generated by $A\cap\mathcal{C}$ on A. Therefore:

$$A\cap\sigma(\mathcal{C})=\sigma_A(A\cap\mathcal{C}) \tag{7.4.26}$$

✍**Example:**

Given the set $E=\{1,2,3,4\},\mathcal{C}=\{\{1,2\},\{3\}\},A=\{3,4\}$ then:

$$A\cap\mathcal{C}=\{\varnothing,\{3\}\}\quad\sigma_A(A\cap\mathcal{C})=\sigma_A\big(\{\varnothing,\{3\}\}\big)=\big\{\varnothing,\{3\},\{4\},\{3,4\}\big\} \tag{7.4.27}$$

and let us check that $A\cap\sigma(\mathcal{C})=\sigma_A(A\cap\mathcal{C})$:

$$\begin{aligned}A\cap\sigma(\mathcal{C})&=\{3,4\}\cap\sigma\big\{\{1,2\},\{3\}\big\}\\&=\{3,4\}\cap\big\{\varnothing,\{3\},\{4\},\{1,2\},\{3,4\},\{1,2,3\},\{1,2,4\},\{1,2,3,4\}\big\}\\&=\big\{\varnothing,\{3\},\{4\},\{3,4\}\big\}\end{aligned} \tag{7.4.28}$$

So the equality is satisfied!

A trivial corollary of this equality is that if we consider a topological space E and $A \subseteq E$ with the induced topology, then:

$$A \cap \mathcal{B}(E) = \mathcal{B}(A) \qquad (7.4.29)$$

We will study more in details later σ-algebras but first let us recall that a tribe (sometimes named "algebra of sets") on E must satisfy the following properties:

P1. Has to contain E

P2. Must be stable by the complementary

P3. Must be stable by countable union or intersection

Let us recall (see section Set Theory page 398) that if we have E that is a set, then for every $A, B \subseteq E$ we define the symmetric difference $A\Delta B$ between A and B by:

$$A\Delta B = (A \setminus B) \cup (B \setminus A) \qquad (7.4.30)$$

Trivial properties are as follows:

P1. A σ-algebra is stable by symmetric difference ($A, B \in \mathcal{A}$ we have $A\Delta B \in \mathcal{A}$)

P2. $A\Delta B = B\Delta A$

P3. $A^c \Delta B^c = A\Delta B$

P4. $A\Delta B = (A \cup B) \setminus (A \cap B)$

Theorem 7.10. If $\mathcal{B}$ is a σ-algebra over E, then $(\mathcal{B}, \Delta, \cap)$ is a "Boolean ring" (or "Boolean algebra" but be careful with the term "algebra" here which can cause confusion with the corresponding structure in Set theory) with $\varnothing$ and E as neutral "additive" element (Δ) and respectively "multiplicative" ($\cap$).

Remark

For reminders on the items listed in the preceding paragraph, the reader can refer to the section of Set Theory at page 378 and the subsection of Boolean Algebra (see section Formal Logic Systems page 7105).

Proof 7.10.1. The "addition" Δ is associative because developing we get (this can verified by an arrow diagram if needed - the "potatoes"):

$$A\Delta(B\Delta C) = (A \cap B \cap C) \cup (A \cap B^c \cap C^c) \cup (A^c \cap B \cap C^c) \cup (A^c \cap B^c \cap C) \qquad (7.4.31)$$

and the latter expression is stable by permutation (commutation) of A and C (same method of verification). Therefore:

$$A\Delta(B\Delta C) = C\Delta(B\Delta A) = (B\Delta A)\Delta C = (A\Delta B)\Delta C \qquad (7.4.32)$$

We check that $\varnothing$ is neutral with respect to the symmetric difference (the proof that E is neutral with respect to inclusion is obvious). It is trivial that:

$$A\Delta\varnothing=\varnothing\Delta A \quad \text{and that} \quad A\Delta A=\varnothing \tag{7.4.33}$$

$(\mathcal{B},\Delta,\varnothing)$ is therefore well an Abelian group with respect to the law Δ (symmetric difference).

Finally $\cap$ is distributive with respect to Δ. Indeed:

$$\begin{aligned} A\cap(B\Delta C)&=A\cap(B\setminus C\cup C\setminus B)\\ &=(A\cap B\setminus C)\cup(A\cap C\setminus B)\\ &=\big(A\cap B\setminus(A\cap C)\big)\cup\big(A\cap C\setminus(A\cap B)\big)\\ &=(A\cap B)\Delta(A\cap C)\end{aligned} \tag{7.4.34}$$

What makes $(\mathcal{B},\Delta,\varnothing)$ is indeed a ring (furthermore of a commutative ring!).

■ Q.E.D.

7.4.1.1 Monotone Classes

Definition (#7.4.313): Let E be a set. A "monotone class" on E is a family $\mathcal{C}$ of subsets of E satisfying the following axioms:

A1. $E \in \mathcal{C}$

A2. $A, B \in \mathcal{C}$ and $A \subseteq B \Rightarrow \setminus A \in \mathcal{C}$

A3. If (A_n) is an increasing sequence (take care to the word "increasing"!) of elements of $\mathcal{C}$ then $\bigcup\limits_{i=1}^{+\infty} A_i \in \mathcal{C}$ (stable by countable increasing union).

Remarks

R1. An increasing sequence of sets is: $A_1 \subseteq A_2 \subseteq A_3 \ldots$

R2. The first two axioms imply that $\mathcal{C}$ is by complementary.

R3. The three axioms together leads to that the monotonous class is stable by decreasing intersection. A way to check this to take the complement of each element of the increasing sequence to fall back on the decreasing sequence and vice versa.

Every σ-algebra is a monotone class, because σ-algebras are closed under arbitrary countable unions and intersections.

Therefore:

$$\mathcal{A} \subseteq \sigma\text{-algebra}(\mathcal{A}) \subseteq \mathcal{M}(\mathcal{A}) \tag{7.4.35}$$

In the same way as for the tribes, if we consider a family $(\mathcal{C}_i)_I$ of monotone classes on E. Then $\bigcap_I \mathcal{C}_i$ is a monotone class (the proof is verified immediately by the three previous axioms).

✍**Example:**

Given E a set, $\mathcal{P}(E)$ is a monotone class on E. More generally, a tribe is a monotone class.

Equivalently to tribes, let us consider a set E and $\mathcal{C} \subseteq \mathcal{P}(E)$. Given $\mathcal{S}$ the family of all monotone class containing $\mathcal{C}$, $\mathcal{S}$ is not empty because $\mathcal{P}(E) \in \mathcal{S}$. We denote by:

$$\mathcal{M}(\mathcal{C}) = \bigcap_{\mathcal{T} \in \mathcal{S}} \mathcal{T} \tag{7.4.36}$$

the monotone class generated by $\mathcal{C}$. Therefore $\mathcal{M}(\mathcal{C})$ is the smallest monotone class containing $\mathcal{C}$ (and satisfying obviously the previous axioms).

Remark

If E is a set and $\mathcal{C} \subseteq \mathcal{P}(E)$ then $\mathcal{C} \subseteq \sigma(\mathcal{C})$, as $\sigma(\mathcal{C})$ is a monotone class (and also a tribe) containing $\mathcal{C}$ and therefore contains also $\mathcal{M}(\mathcal{C})$ (see the examples with tribes).

The theorem (of the monotonic class) is stated as follows:

Theorem 7.11. Given E as set. If $\mathcal{C}$ is a family of parts of E that we impose as stable by finite intersection then $\mathcal{C} = \sigma\mathcal{C}$ (we then have to prove that the smallest tribe of $\mathcal{C}$ is equal to the smallest monotone class of $\mathcal{C}$). If we do not impose that $\mathcal{C}$ is stable by finite intersection we would not have necessarily the equality!

Proof 7.11.1. As already said: $\mathcal{M}(\mathcal{C}) \subseteq \sigma(\mathcal{C})$ (which is trivial). We will prove first that $\mathcal{M}(\mathcal{C})$ is a tribe on E. For this it is sufficient to show that $\mathcal{M}(\mathcal{C})$ is (also) stable by countable union (and not necessarily by an increasing sequence of elements!).

Let us considerate following families for the proof:

$$\begin{aligned}\mathcal{M}_1 &= \left\{A \in \mathcal{M}(\mathcal{C}) | A \cap B \in \mathcal{M}(\mathcal{C}), \forall B \in \mathcal{C}\right\} \\ \mathcal{M}_2 &= \left\{A \in \mathcal{M}(\mathcal{C}) | A \cap B \in \mathcal{M}(\mathcal{C}), \forall B \in \mathcal{M}(\mathcal{C})\right\}\end{aligned} \tag{7.4.37}$$

By the previous definitions $\mathcal{M}_1 \subseteq \mathcal{C}$ but $\mathcal{C}$ being (imposed) stable by finite intersections implies that $\mathcal{C} \subseteq \mathcal{M}_1$ and therefore (it is the same reasoning as for the tribes):

$$\mathcal{C} \subseteq \mathcal{M}_1 \subseteq \mathcal{M}(\mathcal{C}) \tag{7.4.38}$$

$\mathcal{M}_1$ is a monotone class, indeed $E \in \mathcal{M}_1$, if $A_1, A_2 \in \mathcal{M}_1$ and that $A_1 \subseteq A_2$ (second axiom) then:

$$\forall B \in \mathcal{C}, \underbrace{A_1 \cap B}_{\in \mathcal{M}(\mathcal{C})} \subseteq \underbrace{A_2 \cap B}_{\in \mathcal{M}(\mathcal{C})} \tag{7.4.39}$$

and therefore (which supports the fact that the other elements (A_n) satisfy the previous relation):

$$\forall B \in \mathcal{C}, (A_2 \cap B) \setminus (A_1 \cap B) \in \mathcal{M}(\mathcal{C}) \Rightarrow (A_2 \setminus A_1) \cap B \in \mathcal{M}(\mathcal{C}) \tag{7.4.40}$$

If (A_n) is an increasing sequence of elements of $\mathcal{M}_1$ then:

$$\forall B \in C, \left(\bigcup A_n\right) \cap B = \bigcup \underbrace{(A_n \cap B)}_{\in \mathcal{M}(\mathcal{C})} \in \mathcal{M}(\mathcal{C}) \tag{7.4.41}$$

as $(A_n \cap B)$ is an increasing sequence.

Therefore $\mathcal{M}_1$ is indeed a monotone class and by $\mathcal{C} \subseteq \mathcal{M}_1 \subseteq \mathcal{M}(\mathcal{C})$, we therefore have:

$$\mathcal{M}_1 = \mathcal{M}(\mathcal{C}) \tag{7.4.42}$$

The latter equality implies $\mathcal{C} \subseteq \mathcal{M}_2$. As for $\mathcal{M}_1$, we show that $\mathcal{M}_2$ is a monotone class and therefore $\mathcal{C} = \mathcal{M}_2$, which means by extension that $\mathcal{M}(\mathcal{C})$ is therefore stable by finite intersections.

$\mathcal{M}(\mathcal{C})$ being stable by complementary this takes us to that $\mathcal{M}(\mathcal{C})$ is, we just proved it, stable by finite unions (but we want to prove that it is stable by countable union!).

Given now a sequence (A_n) of elements of $\mathcal{M}(\mathcal{C})$. We consider the sequence:

$$B_n = \bigcup_{i=1}^{n} A_i \tag{7.4.43}$$

(B_n) is an increasing sequence of elements of $\mathcal{M}(\mathcal{C})$, therefore:

$$\bigcup_{n=1}^{+\infty} B_n \in \mathcal{M}(\mathcal{C}) \tag{7.4.44}$$

but:

$$\bigcup_{n=1}^{+\infty} B_n = \bigcup_{n=1}^{+\infty} A_n \tag{7.4.45}$$

Therefore:

$$\bigcup_{n=1}^{+\infty} A_n \in \mathcal{M}(\mathcal{C}) \tag{7.4.46}$$

Therefore $\mathcal{M}(\mathcal{C})$ is stable by countable union and finally $\mathcal{M}(\mathcal{C})$ is a tribe. But as $\mathcal{C} \subseteq \mathcal{M}(\mathcal{C})$ this brings us to $\mathcal{M}(\mathcal{C}) = \sigma(\mathcal{C})$.

■ Q.E.D.

We will later see some important applications of this theorem (but first we want to improve the above text with figure and more simple and practical examples!).

7.4.2 Lebesgue measure in probabilities

Probability Theory has become increasingly important in multiple parts of science (and therefore engineering too!) as we have already mentioned it during our study of the topic. Getting deeply into Probability Theory requires a full book, not just a chapter as we also already know. For readers who intend to pursue further studies in the roots of Probability Theory, this subsection will give you a good head start. For readers not intending to delve further into the roots of Probability Theory, this subsection will give you a taste of the subject.

Modern Probability Theory makes major use of Measure Theory. As we will see, a probability measure is simply a measure such that... the measure of the whole space equals 1. Thus a thorough understanding of the paragraphs that will follow dealing with Measure Theory and integration provides a solid foundation for Probability Theory!

Studying modern Probability Theory based on Measure Theory helps through rigorous proofs and definitions to explain to engineers or scientifically illiterate people typically why:

- A punctual estimation has a probability of zero in all problems involving variables (or combination of variables) having for domain of definition $\mathbb{R}$ and therefore such an estimation doesn't make sense rigorously speaking

- The previous point explain why we should always in such cases compute ranges of estimation that are plausible rather than punctual estimation that have zero probability
- A event having a probability of zero doesn't mean it can't happen
- That in an infinite universe with an infinite time a sequence of events has a probability of 1 to occur (see page 455)

Now that we have some basic measure theory, let's go back to the definition of "probability". A probability space is simply a measure space where the measure assigned to the entire object is one!

Definition (#314): A "probability space" W is a unique triple $W=\{\Omega,\mathcal{F},P\}$ where :

- Ω is its sample space
- $\mathcal{F}$ its σ-algebra of events
- P its probability measure

For reminder:

- The object Ω, named the "sample space", represents all the conceivable futures of the universe. Let's consider a simple coin flip. Before we flip the coin, there are a bunch of conceivable ways in which the coin spins through the air and settles on the table. The set of outcomes is a theoretical representation of all possible conceivable futures in which this process will unfold.
- The σ-algebra, is simply a way of partitioning all of these conceivable futures. Each of these partitions is named an "event". For example in some set of futures, the coin lands on heads - in which case, we would say that the event "heads" occurred. In other futures, the coin lands as "tails". If one of these futures occurs, then we say the event "tails" occurred.
- The probability measure assigns a degree of certainty towards each partition of the conceivable futures. Specifically, the probability measure assigns each event $\omega\in\Omega$ a value between 0 and 1 , which represents our degree of certainty that our future will be contained in ω. Specifically, 1 represents full certainty that our future will be contained in the event ω and 0 represents full certainty that our future will not be contained in ω.

Definition (#315): A "random variable" is a mapping:

$$X:\Omega\rightarrow\mathbb{R} \tag{7.4.47}$$

that assigns a real number $X(\omega)$ to each outcome ω.

All of this begs the question, why do we need Measure Theory for all of this? First we see that Measure Theory provides a natural description of uncertainty in the following ways:

- A σ-algebra gives us a way to ensure that if we are discussing our certainty towards an event occurring, we can also discuss our certainty towards the event not occurring. That is, the complement of any element of the σ-algebra is also in the σ-algebra.
- The σ-algebra ensures that we can discuss the probability of unions and intersections of events. The fact that $P(\varnothing):=0$ expresses the impossibility that no outcome in the sample space occurs. That is, we are certain to see some conceivable future.
- The fact that $P(\Omega):=1$ expresses that some outcome of the sample space will certainly occur. That is, 1 is the value that equates to maximal certainty.
- Uncertainty has a "size" in the following sense: if we have two disjoint events, then the probability of either of these events occurring should be the sum of the probabilities of the individual events. By using a measure space to model uncertainty, we ensure that given $A,B\subset\Omega$ where $A\cap B=\varnothing$, it follows that $P(A\cup B)=P(A)+P(B)$.

Remarks

R1. The sample "Universe" space Ω is the set of all possible samples or elementary events $\omega:\Omega=\{\omega\,|\,\omega\in\Omega\}$.

R2. The σ-algebra $\mathcal{F}$ is the set of all of the considered events A, i.e., subsets of $\Omega:\mathcal{F}=\{A\,|\,A\subseteq\Omega,A\in\mathcal{F}\}$.

R3. The probability measure P assigns a probability $P(A)$ to every event $A\in\mathcal{F}:P:\mathcal{F}\rightarrow[0,1]$. With $P(\Omega)=1$ and $P(\omega_i)=p_i$.

Suppose $n\in\mathbb{Z}^+$ and Ω is a set containing exactly n elements. Let $\mathcal{F}$ denote the collection of all subsets of Ω. Then:

$$\frac{\text{counting measure on }\Omega}{n}$$

is a probability measure P on $(\Omega,\mathcal{F})$. Obviously on uncountable sets like $\mathbb{R}$ or $\mathbb{R}^+$ that are frequent in engineering, we have $P(\omega)=0$.

✍**Example:**

As a more specific example of the previous item, suppose that $\Omega=\{40,41,\ldots,49\}$ and $P=(\text{counting measure on }\Omega)/10$. Let $A=\{\omega\in\Omega:\omega\text{ is even }\}$ and $B=\{\omega\in\Omega:\omega\text{ is prime }\}$. Then $P(A)$ [which is the probability that an element of this sample space Ω is even] is $\frac{1}{2}$ and $P(B)$ [which is the probability that an element of this sample space Ω is prime] is $\frac{3}{10}$.

Definition (#316): The "Borel σ-algebra" is the smallest σ-algebra (see page 2483) containing open interval in $\mathbb{R}$. The sets in $\mathcal{B}(\mathbb{R})$ are named "Borel sets". The extension to the multi-dimension case $\mathcal{B}(\mathbb{R}^n)$, is straightforward. The Borel σ-algebra therefore includes all subsets of $\mathbb{R}$ which are of interest in practical applications (scientific or engineering).

Let λ denote Lebesgue measure on $\mathbb{R}$, and let $\mathcal{B}$ denote the σ-algebra of Borel subsets of $\mathbb{R}$. Define a density distribution function $h:\mathbb{R}\rightarrow[0,+\infty[$. Then $hd\lambda$ is a probability measure on $(\mathbb{R},\mathcal{B})$.

Definition (#317): Suppose $(\Omega, \mathcal{F}, P)$ is a probability space. An event A is said to happen "almost surely" if the probability of A is 1, or equivalently if $P(\Omega \backslash A) = 0$.

7.4.2.1 Lebesgue Measure of the rational and irrational numbers

We can now begin to calculate the Lebesgue measure of the rational numbers! The calculation uses the first following lemma:

Lemma 7.11.1. If $X \subseteq Y$ are both measurable sets, $\mu(X) \leq \mu(Y)$. While this statement is quite intuitive (a subset should not be larger than it's superset), we give the short proof:

Proof 7.11.2. We may decompose Y as $Y = X \cup (Y \backslash X)$ (here $Y \backslash X$ is the relative complement of X in Y). Since X and $Y \backslash X$ are disjoint, by the third property (countable additivity) of the Lebesgue measure μ introduced earlier above (see page 2484):

$$\mu(Y) = \mu(X) + \mu(Y \backslash X) \geq \mu(X) \tag{7.4.48}$$

since $\mu(Y \backslash X) \geq 0$.

■ Q.E.D.

We now prove the next lemma:

Lemma 7.11.2. The Lebesgue measure of any singleton set, $\{x\}$, is zero.

Proof 7.11.3. This fact is intuitive, because a singleton is the smallest possible nonempty set; if we are to have any nonempty sets of measure zero, surely they must include the singletons.

Let x be any real number. The set $\{x\}$ is measurable, and for any $\varepsilon > 0$, $\{x\} \subset \left(x - \frac{\varepsilon}{2}, x + \frac{\varepsilon}{2}\right)$. Therefore:

$$\begin{aligned} 0 &\leq \mu(\{x\}) \\ &\leq \mu\left(\left(x - \frac{\varepsilon}{2}, x + \frac{\varepsilon}{2}\right)\right) \\ &= x + \frac{\varepsilon}{2} - \left(x - \frac{\varepsilon}{2}\right) \\ &= \varepsilon \end{aligned} \tag{7.4.49}$$

so $0 \leq \mu(\{x\}) \leq \varepsilon$. Since $\varepsilon > 0$ was arbitrary, we may let $\varepsilon \rightarrow 0$, which shows that $\mu(\{x\}) = 0$.

■ Q.E.D.

Finally, we are in a position to calculate the Lebesgue measure of the rational numbers:

Proof 7.11.4. Since the rationals are countable, we may enumerate them as $\mathbb{Q} = \cup_{i=1}^{+\infty} \{q_i\}$, so:

$$\mu(\mathbb{Q}) = \sum_{i=1}^{+\infty} \mu\left(\{q_i\}\right) = \sum_{i=1}^{+\infty} 0 = 0 \tag{7.4.50}$$

We have arrived at the remarkable (and counter-intuitive) fact that the Lebesgue measure of the rational numbers is zero. In a very precise sense, almost all real numbers are not rational.

■ Q.E.D.

The reader must keep in mind that we have this result because the set of rational numbers is countable. One of the properties of Lebesgue measure (as opposed to Peano-Jordan measure, for example) is that the measure of a countable union of disjoint sets is the sum of the measures of the individual sets. A single point has Lebesgue measure zero, so a countable set, being a countable union of singletons, also has Lebesgue measure zero!

Returning to the problem of comparing the size of the rational to the unit interval $[0,1]$, which motivated our introduction of measure theory above. The measure of the unit interval is $\mu([0,1])=1$, so the interval is larger than the rationals.

Remark

Diligent readers may have noticed that our proof that the rational numbers have measure zero may be applied to any countable subset of the real numbers. While this may seem to validate our initial idea that the small sets of the real are those that are countable, it is not true. The Cantor set (see section Fractals page 7049), a well-known example in analysis and topology, is uncountable and has measure zero. Therefore the class of small subsets of the real numbers is much larger than just the countable subsets.

Let P denote Lebesgue measure on the interval $[0,1]$. If $\omega\in[0,1]$, then ω is almost surely an irrational number (because the set of rational numbers has Lebesgue measure 0).

This example shows that an event having probability 1 (equivalent to happening almost surely) does not mean that the event definitely happens. Conversely, an event having probability 0 does not mean that the event is impossible. Specifically, if a real number is chosen at random from $[0,1]$ using Lebesgue measure as the probability, then the probability that the number is rational is 0, but that event can still happen.

In other words, zero probability does not mean that event is impossible. Every time you pick a random number from $[0,1]$, you have an infinite set of possible outcomes, so probability of picking a number from any finite subset of $[0,1]$ is equal to zero. However, impossible event is defined otherwise: It's an event which can't happen due to experiment conditions. In this case it's picking any number outside of $[0,1]$.

Thus, impossible and zero-probable events have the same probability of 0, however impossible events never happen, while zero-probable events are possible! This is sometimes named the "miracle theorem". That's why in science a "miracle" is associated to an impossible event but most people who don't have a graduate level in science education associate miracles (wrongly!) to zero-probable events... It follows from the fact that a length of segment $[1,1]$ (single point, i.e. "singleton") is 0, however point 1 (as well as any other point) exists.

At this point the reader can now understand what we stated earlier:

- A punctual estimation has a probability of zero in all problems involving variables (or combination of variables) having for domain of definition $\mathbb{R}$ and therefore such an estimation doesn't make sense rigorously speaking

- The previous point explain why we should always in such cases compute ranges of estimation that are plausible rather than punctual estimation that have zero probability

- An event having a probability of zero doesn't mean it can't happen

Caution! On the internet, and in particular on social networks (unsurprisingly...), propagates a disinformation which consists of asserting (obviously without proof!), that if a probability is sufficiently small, then the related event can be considered as having a probability strictly equal to zero and therefore be an impossible event. This is obviously false and we have therefore proven it above! It's also very easy to refute this dumb claim experimentally just by using a few dozens of hexagonal dice (among many other possibilities!).

> *The theory of probability [...] becomes the happiest supplement to the ignorance and weakness of the human mind. If we consider the analytical methods to which this theory gave birth, the truth of the principles which serve as its basis, the fine and delicate logic which their use requires in the solution of problems, the establishments of public utility which rely on it, and the extension which it has received and which it can still receive, by its application to the most important questions of natural philosophy and moral sciences; if we then observe that in the very things which can be subjected to calculation, it gives the surest insights which can guide us in our judgements, and that it learns to guard against the illusions which often lead us astray, we will see that there is no science more worthy of our meditations and that it is more useful to introduce into the system of public education.*

8.1. Trigonometry

TRIGONOMETRY is part of the science of geometry. Geometry whose etymological root is "measure of the Earth", trigonometry has etymological root "measuring of body with three angles (trine)". Thus the trigonometry is a branch of mathematics that studies relations involving lengths and angles of triangles.

There are currently four known trigonometries (defined) commonly used in mathematics: the "circle trigonometry" (assimilated with the study of "circular functions"), the "hyperbolic trigonometry" and "spherical trigonometry" and the more exotic "elliptical trigonometry" (related to the elliptic integrals and their related elliptic function). We propose in the text that follows an attempt to a fairly rigorous approach to all the most famous relations of the three first type of trigonometries (the last one - the elliptical trigonometry - will be reserved to another section of this textbook).

Remarks

R1. We will not deal here on the quadratic and rhombic trigonometries that are used by the electricians and have little or no interest in theoretical physics. The same remark is valid for the lemniscatique trigonometry which is related to pure mathematics and in particular to the Riemann zeta function.

R2. The reader who is looking for the proofs of derivatives and integrals of trigonometric functions defined below should read the Differential and Integral Calculus section (see chapter Algebra page 1450) where the derivatives and integrals of common trigonometric functions are all proven.

The purpose of this section will be to determine the most common relations in trigonometry and that are used extensively in all sections of this textbook (Mechanics, Astronomy, Statistics, Atomistic, etc.). Note that the majority of the relations (but not all!) that we will define and prove were determined in the 116th century (holocene calendar) by algebraists like Viète.

8.1.1 Radian

When we speak about trigonometry, the first thing that should come to mind and emerge as standard for plan angles measurements (see the section of Euclidean Geometry chapter for the definition of the concept of angle) is the notion of "radians ".

Definition (#8.1.318): 1 "radian" (denoted sometimes [rad]) is the angle described by a plane secant to a circle passing through its center as the arc thus defined by the horizontal axis passing through the center of the circle and the secant is equal in length to the radius of this circle.

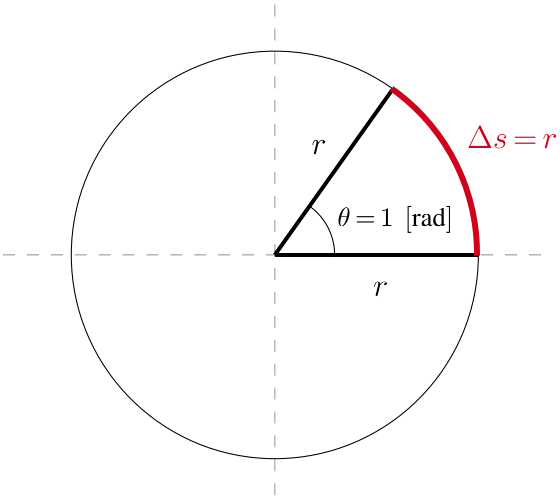

Figure 8.1: **Schematic definition of the radian**

Remark

The radian is widely used in physics, as we will see it in the corresponding chapters of this textbook, when angular measurements are required. For example, angular velocity is typically measured in radians per second ([rad/s]). One revolution per second is equal to 2π radians per second.

For example, for a circle of radius $R=1$ therefore of circumference (or "perimeter") $P=2\pi R = 2\pi$ the length of the arc defined by a secant having an angle of 1 radian with respect to the horizontal passing through the center of the circle will be equal 1.

Hence it follows that the angle for a "round" of the circle will be:

$$2\pi \text{ [rad]} \tag{8.1.1}$$

This can be summarized in the following drawing:

Figure 8.2: **A chart to convert between degrees and radians (source: Wikipedia)**

The previous example can be generalized to any circle of radius R as the angle for a complete tour will always be for 2π[rad] a whole turn-around, π[rad] for a half turn-around and $\dfrac{\pi}{2}$[rad] for fourth turn-around...

Unfortunately in high-schools most teachers still teach children to measure angles in degrees. Fortunately conversion to do is not too difficult ... (it's a simple rule of three):

$$\boxed{\text{angle in radians} = \text{angle in degrees} \cdot \frac{\pi}{180}} \tag{8.1.2}$$

Let r be the measurement of an angle in radians, d the measurement of the same angle in degrees, g and the measurement of the same angle in gradients (old unit) we have by definition:

$$\boxed{\frac{r}{2\pi} = \frac{d}{360} = \frac{g}{400}} \tag{8.1.3}$$

Astronomers and astrophysicists like to talk in minutes or seconds of arc such as:

$$1^\circ = 60' \text{ minutes arc} \qquad 1' = 60'' \text{ seconds arc} \tag{8.1.4}$$

For example if the Moon has a diameter angle (i.e. angular diameter) of approximately $29'$ ($0.5°$) in the sky and if our eyes would have a deep exposure capability we would be able to see that Andromeda (M31) has a diameter angle of $178'$ ($3°$), therefore about 6 times as wide as the Moon!

60"
60°35'18"

Figure 8.4: Degrees, minutes of arc, seconds of arc (author: ?)

✍**Example:**

Imagine you are observing at the zenith (at your perpendicular from the ground) a huge sphere of 51 kilometers in radius and at distance of $5,000$ kilometres.

The angular size of this object when it is at your zenith is given by:

$$\alpha = \tan\left(\frac{51}{5000}\right) \cong 0.01 \cong 0.573^\circ = 0^\circ 34' 22.8" \tag{8.1.5}$$

Now consider this same object at the ground level but further away from you at a distance of $20,000$ kilometres. Now its angular size is:

$$\alpha = \tan\left(\frac{51}{5000}\right) \cong 0.0025 \cong 0.143^\circ = 0^\circ 8' 34.8" \tag{8.1.6}$$

Hence its size between the two positions change of approximately a factor 4.

8.1.2 Circle Trigonometry

Consider the figure below showing any circle centered at the origin in a direct basis:

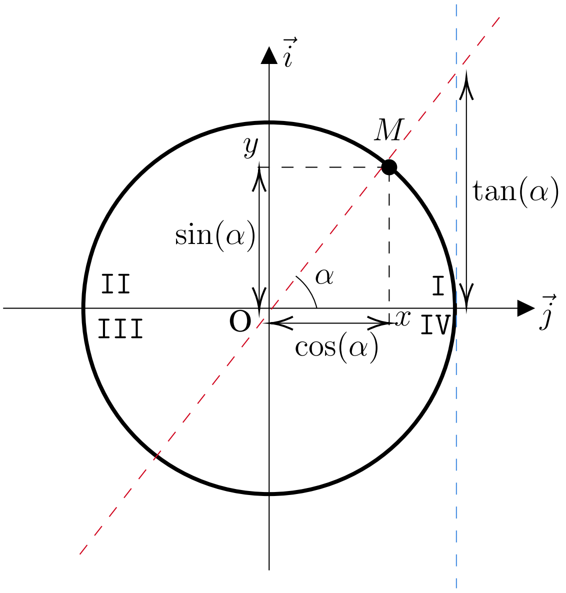

Figure 8.5: **Construction idea of elementary (circle) trigonometric functions**

First, by applying the Pythagorean theorem (see section Euclidean Geometry page 2609) in the visible right triangle above, we get:

$$\|\overrightarrow{\mathrm{O}M}\|=R=\sqrt{x^2+y^2} \tag{8.1.7}$$

where R is the radius of the circle.

To define the trigonometric functions for the angle α, start with any right triangle that contains the angle α. The three sides of the triangle are named as follows:

1. The "hypotenuse" is the side opposite the right angle, in this case the side is the segment $\overline{\mathrm{O}M}$. The hypotenuse is always the longest side of a right-angled triangle.
2. The "opposite side" is the side opposite to the angle we are interested in.
3. The "adjacent side" is the side adjacent to the angle we are interested in.

From this representation we can define mathematical entities named "trigonometric functions of the circle", also sometimes named by the ancient (...) "cyclometrics functions", such as (for the most known one):

$$\boxed{\begin{array}{lll}\cos(\alpha)=\dfrac{x}{R}=\dfrac{\text{adjacent}}{\text{hypotenuse}} & \arccos\left(\dfrac{x}{R}\right)=\alpha & \sec(\alpha)=\dfrac{1}{\cos(\alpha)}=\cos^{-1}(\alpha)\\ \sin(\alpha)=\dfrac{y}{R}=\dfrac{\text{opposite}}{\text{hypotenuse}} & \arcsin\left(\dfrac{y}{R}\right)=\alpha & \csc(\alpha)=\dfrac{1}{\sin(\alpha)}=\sin^{-1}(\alpha)\\ \tan(\alpha)=\dfrac{y}{x}=\dfrac{\text{opposite}}{\text{adjacent}} & \arctan\left(\dfrac{y}{x}\right)=\alpha & \cot(\alpha)=\dfrac{1}{\tan(\alpha)}=\tan^{-1}(\alpha)\end{array}} \tag{8.1.8}$$

Be careful because depending on the authors and on the context (and that's our case!) $\arccos, \arcsin, \arctan$, are respectively denoted by $\cos^{-1}, \sin^{-1}, \tan^{-1}$.

Read "cosine" for "cos", "sine" for "sin", "tangent" for "tan", "cotangent" for "cot", "secant" for "sec", "cosecant" for "csc".

"SOHCAHTOA" is a mnemonic acronym used to remember the three main trigonometric ratios (sine, cosine, tangent) in a right-angled triangle. It breaks down as Sine = Opposite/Hypotenuse (SOH) ; Cosine = Adjacent/Hypotenuse (CAH), and Tangent = Opposite/Adjacent (TOA).

Remarks

R1. When the context allows it, and that there can not be any ambiguity, the parentheses after the name of the trigonometric function may be omitted (this is often the case in physics).

R2. The arc... functions are obviously the reciprocal functions of the trigonometric functions!

In practice (school or high level engineering) you have to take care to two important properties:

1. Trigonometric functions are far from being bijective. Indeed, they tend to repeat themselves periodically as we will see further below. Nonetheless with a little restriction on their definition domain, they may acquire this quality. In this context, the perspective of a reciprocal becomes possible.

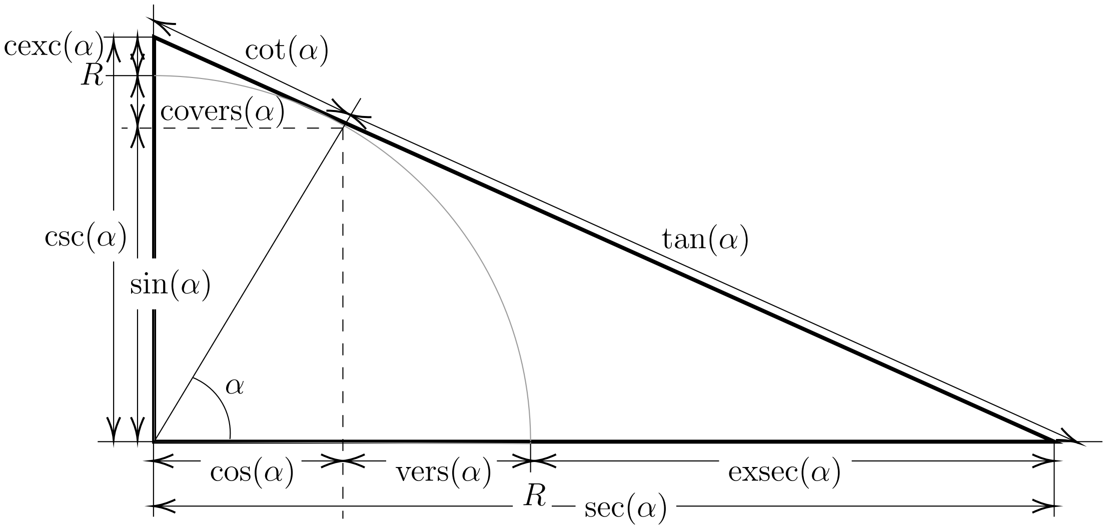
2. If the sign of the bracket of the arc tangent is negative, then we do not know exactly in which quadrant (I, II, III or IV) we are so we do not know the sign of the numerator or denominator! It is for this reason that most calculators and softwares have two arc tangent functions: `arctan` and `arctan2`. The first gives an angle between $\left[-\dfrac{\pi}{2},+\dfrac{\pi}{2}\right]$ and therefore we can not know precisely in which quadrant we are. The second gives us an angle between $[-\pi,\pi]$ so we can know in which quadrant we are but we must provide the sign of the numerator or denominator.

From these functions, we can make some combinations and define simple but remarkable relations but whom usefulness is debatable (and which are very rarely used) such as:

$$\begin{aligned}\text{covers}(\alpha)&=1-\sin(\alpha)\\ \text{vers}(\alpha)&=1-\cos(\alpha)\\ \text{cexc}(\alpha)&=\csc(\alpha)-1\\ \text{exsec}(\alpha)&=\sec(\alpha)-1\end{aligned} \tag{8.1.9}$$

but you will never meet these functions in this textbook because we personally never use such notations (it is rather customary in some U.S. books).

Here is a nice figure... that resume all that stuff:

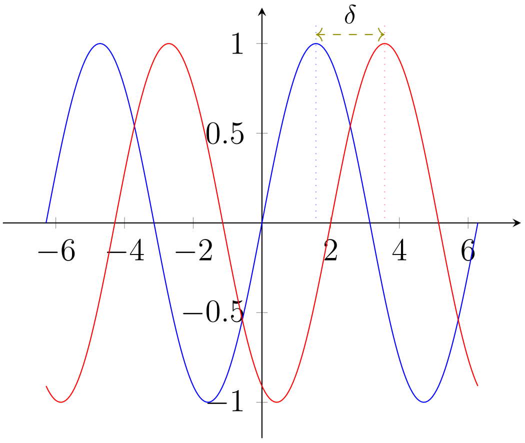


cexc(α)
R
cot(α)
covers(α)
csc(α)
sin(α)
tan(α)
α
cos(α)
vers(α)
R
exsec(α)
sec(α)

Figure 8.6: **Design principle of common circle trigonometric functions**

Definition (#8.1.319): We name "phase-shift" the angle δ that shift any trigonometric function argument of a given value. For example as illustrated below:

$$\sin(x+\delta) \tag{8.1.10}$$



OK for people reading this textbook on a computer with Adobe Flash player installed and activated, here is an animated version (otherwise see here: `https://vimeo.com/575748635`):

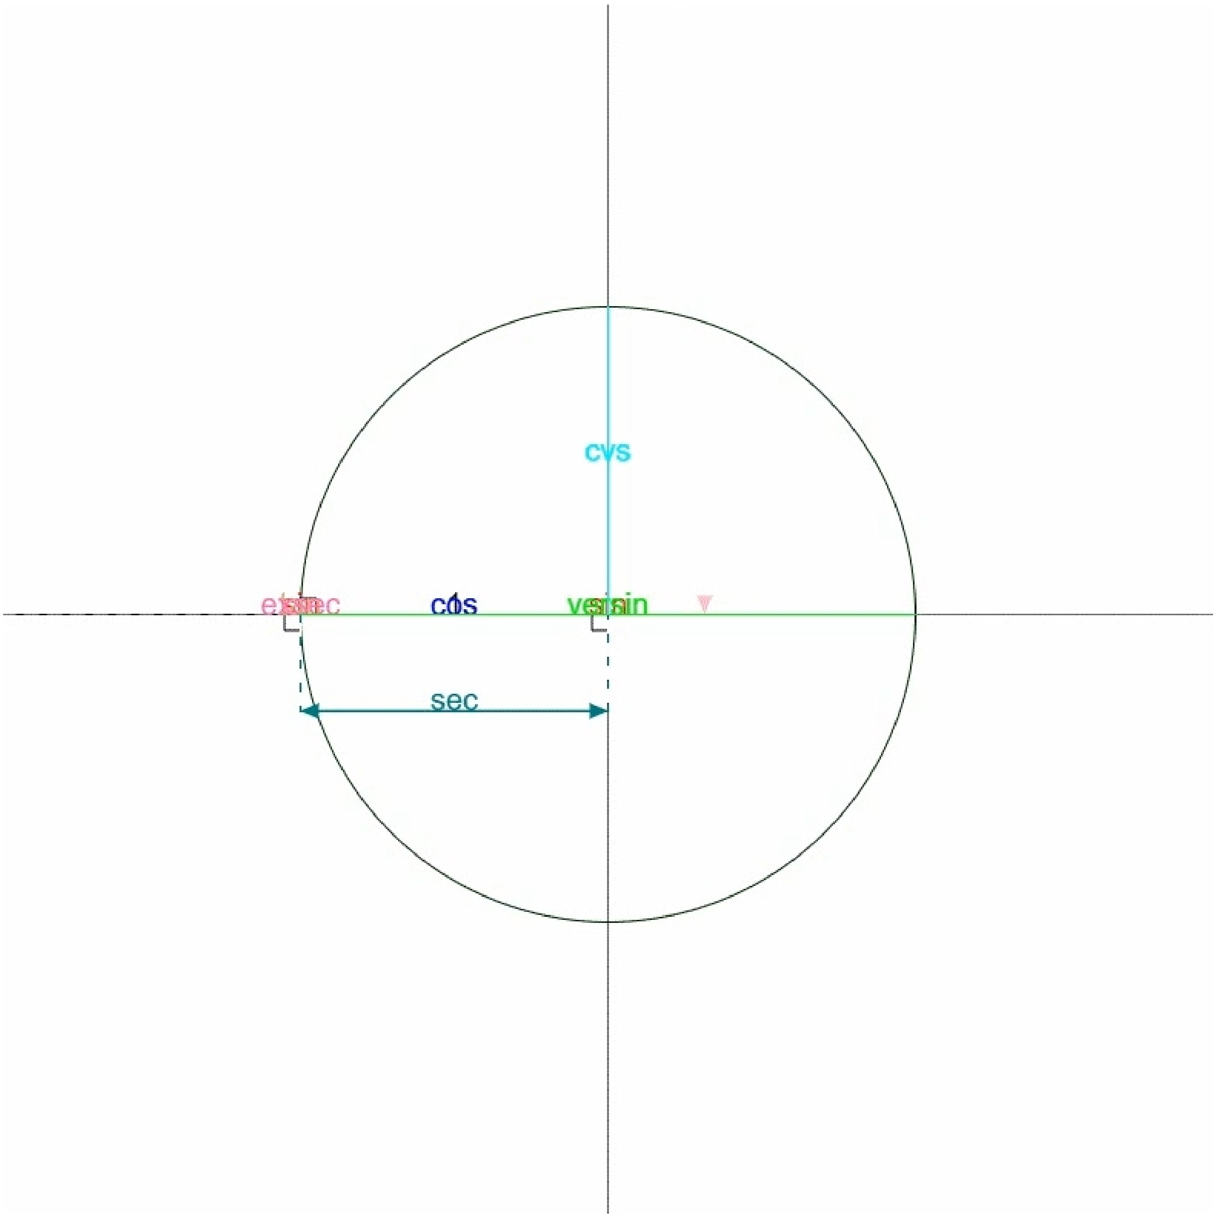


Figure 8.7: **Animation of the trigonometric circle**

Let us see now some very simple angular properties of these common functions:

P1. If we remain in the study of the circle, hence named "trigonometric circle", we must put for the above definitions: $R=1$. Thus, it appears more clearly the physical meaning of these definitions and it will result in a number of properties and applications directly usable in theoretical physics and pure mathematics.

Indeed, if $R=1$ we trivially have (see section Vector Calculus page 1863):

$$\overrightarrow{\text{O}M}=\cos(\alpha)\vec{i}+\sin(\alpha)\vec{j} \tag{8.1.11}$$

and by applying the Pythagorean theorem (see section Euclidean Geometry page 2609):

$$\|\overrightarrow{\text{O}M}\|=1=\sqrt{\cos^2(\alpha)+\sin^2(\alpha)} \tag{8.1.12}$$

Therefore:

$$\boxed{\cos^2(\alpha)+\sin^2(\alpha)=1} \tag{8.1.13}$$

P2. If α is a real number, and for $\forall k \in \mathbb{N}$, the real numbers α and $\alpha+2k\pi$ are associated with the same point M by the periodicity of the unit circle. Indeed, α and $\alpha+2k\pi$ are two measures of the same oriented angle. So:

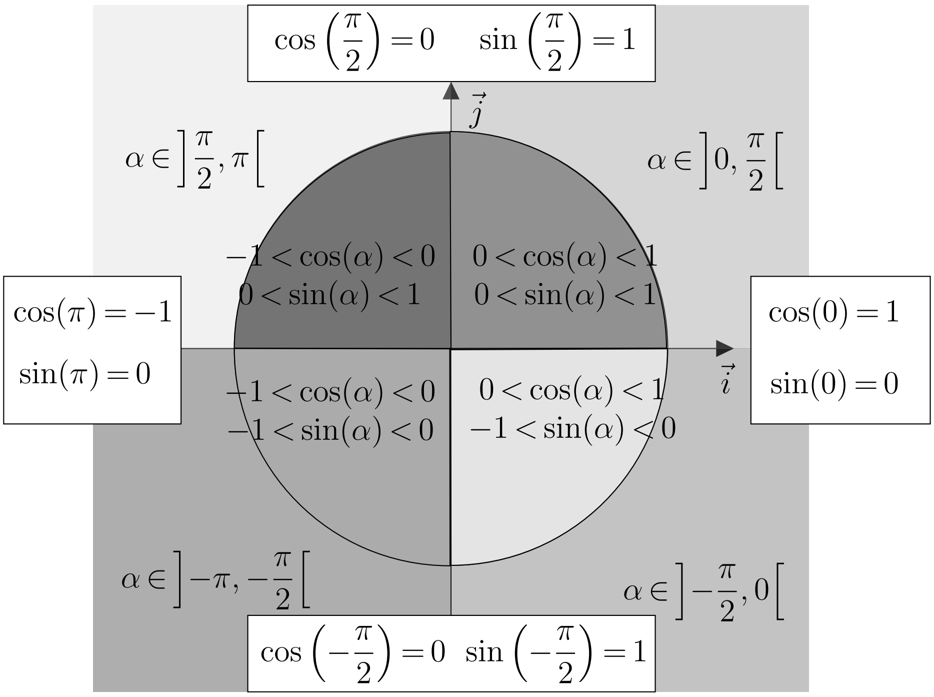
$$\forall\alpha\in\mathbb{R},\forall k\in\mathbb{N}\quad \cos(\alpha\pm 2k\pi)=\cos(\alpha)\text{ and }\sin(\alpha\pm 2k\pi)=\sin(\alpha) \tag{8.1.14}$$

Ditto for all trigonometric functions arising from the definition of sine and cosine functions.

Remark

In the measure of "oriented angles", we say that two measures are congruent modulo $2k\pi$ [rad] if and only if their difference is a multiple of $2k\pi$ [rad]. This characterize two measurements of the same angle.

By definition, the sine and cosine of any real number part of the interval $[-1,+1]$. Specifically, the position of the point M allows us to learn more about the cosine and sine of α. So:



$\cos\left(\frac{\pi}{2}\right)=0 \quad \sin\left(\frac{\pi}{2}\right)=1$
$\vec{j}$
$\alpha\in\left]\frac{\pi}{2},\pi\right[$
$\alpha\in\left]0,\frac{\pi}{2}\right[$
$-1<\cos(\alpha)<0$
$0<\sin(\alpha)<1$
$0<\cos(\alpha)<1$
$0<\sin(\alpha)<1$
$\cos(\pi)=-1$
$\sin(\pi)=0$
$\cos(0)=1$
$\sin(0)=0$
$\vec{i}$
$-1<\cos(\alpha)<0$
$-1<\sin(\alpha)<0$
$0<\cos(\alpha)<1$
$-1<\sin(\alpha)<0$
$\alpha\in\left]-\pi,-\frac{\pi}{2}\right[$
$\alpha\in\left]-\frac{\pi}{2},0\right[$
$\cos\left(-\frac{\pi}{2}\right)=0 \quad \sin\left(-\frac{\pi}{2}\right)=1$

Figure 8.8: **Remarkable angles of common circle trigonometric functions**

There is also another representation of the trigonometric functions of the circle, a bit more technical but almost important to understand well later, at least visually, for the study of wave mechanics (see section of the same name page 3475):

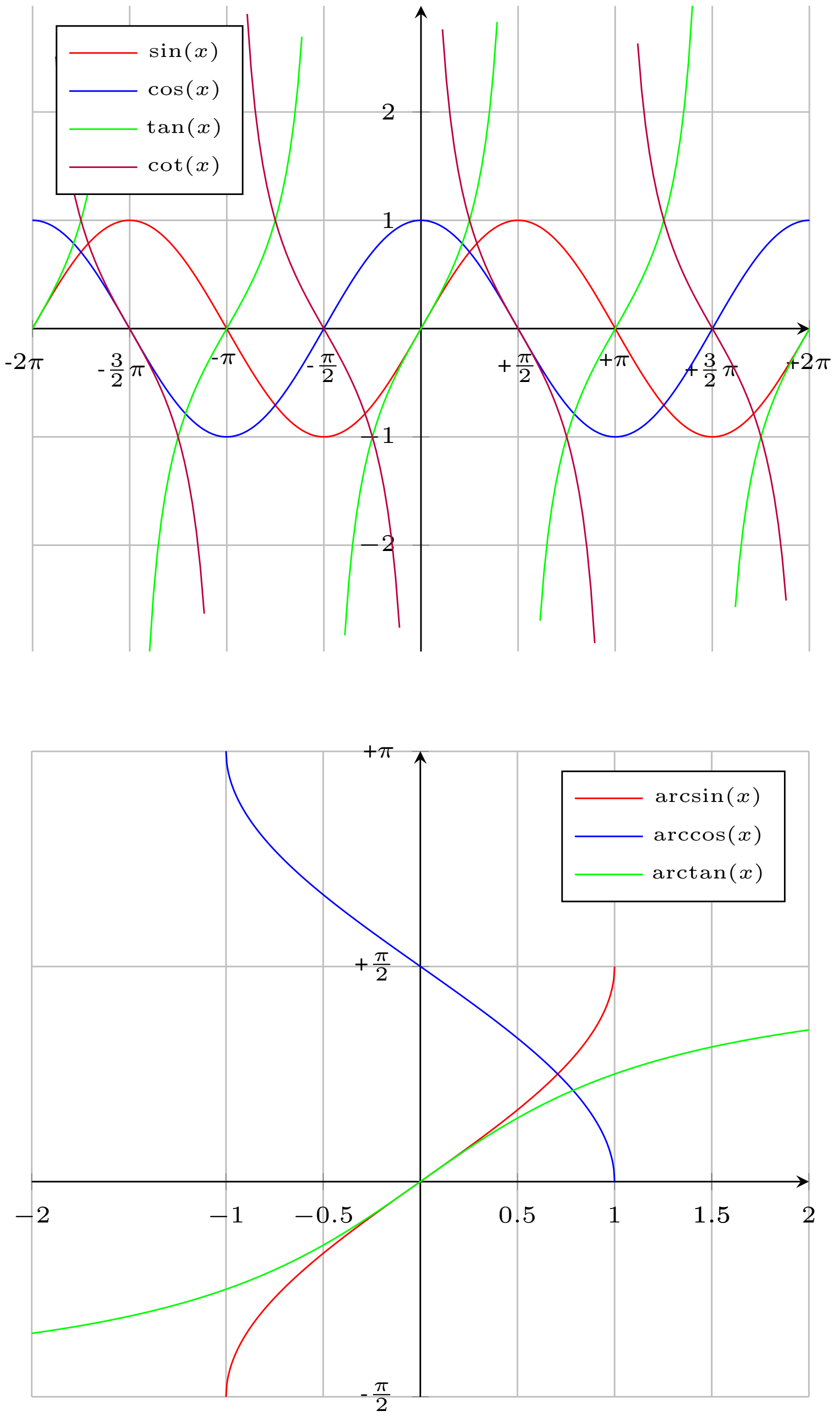


Figure 8.9: Plots of some common circle trigonometric functions

The reader should notice at this point without too much difficulties the following properties (often used in physics!) with $n \in \mathbb{Z}$:

$$\begin{aligned} \sin(n\pi) &= 0 \\ \cos(n\pi) &= (-1)^n \\ \sin\left((2n+1)\frac{\pi}{2}\right) &= (-1)^n \\ \cos\left((2n+1)\frac{\pi}{2}\right) &= 0 \end{aligned} \tag{8.1.15}$$

and easily recognize that the sine is an odd function and the cosine an even function (observation that we often will be useful in various mathematical developments on trigonometric series).

As we saw at the beginning of this section, following the definition of the trigonometric functions we obviously have:

$$\tan(\alpha)=\frac{\sin(\alpha)}{\cos(\alpha)}\qquad \cot(\alpha)=\frac{1}{\tan(\alpha)}=\frac{\cos(\alpha)}{\sin(\alpha)}\tag{8.1.16}$$

and also:

$$\cos^2(\alpha)+\sin^2(\alpha)=1\Leftrightarrow\frac{\cos^2(\alpha)}{\sin^2(\alpha)}+1=\frac{1}{\sin^2(\alpha)}\Leftrightarrow\cot^2(\alpha)+1=\frac{1}{\sin^2(\alpha)}\tag{8.1.17}$$

In exactly the same way we prove that:

$$\tan^2(\alpha)+1=\frac{1}{\cos^2(\alpha)}\tag{8.1.18}$$

From previous equalities we found without too much difficulty (elementary algebra):

$$\sin(\alpha)=\sqrt{1-\cos^2(\alpha)}=\sqrt{1-\frac{1}{1+\tan^2(\alpha)}}=\frac{\tan(\alpha)}{\sqrt{1+\tan^2(\alpha)}}=\frac{1}{\sqrt{1+\cot^2(\alpha)}}\tag{8.1.19}$$

We have identically:

$$\cos(\alpha)=\sqrt{1-\sin^2(\alpha)}=\sqrt{1-\frac{1}{1+\cot^2(\alpha)}}=\frac{\cot(\alpha)}{\sqrt{1+\cot^2(\alpha)}}=\frac{1}{\sqrt{1+\tan^2(\alpha)}}\tag{8.1.20}$$

By reverse reasoning we get just as easily:

$$\begin{aligned}\tan(\alpha)&=\frac{\sin(\alpha)}{\sqrt{1-\sin^2(\alpha)}}=\frac{\sqrt{1-\cos^2(\alpha)}}{\cos(\alpha)}\\\cot(\alpha)&=\frac{\cos(\alpha)}{\sqrt{1-\cos^2(\alpha)}}=\frac{\sqrt{1-\sin^2(\alpha)}}{\sin(\alpha)}\end{aligned}\tag{8.1.21}$$

It could comes without difficulty by observing the unit circle with its remarkable angles that:

$$\begin{aligned}&\sin(-\alpha)=-\sin(\alpha)\\&\sin(\pi\pm\alpha)=\mp\sin(\alpha)\\&\sin\left(\frac{\pi}{2}\pm\alpha\right)=\cos(\alpha)\\[2ex]&\cos(-\alpha)=\cos(\alpha)\\&\cos(\pi\pm\alpha)=-\cos(\alpha)\\&\cos\left(\frac{\pi}{2}\pm\alpha\right)=\mp\sin(\alpha)\\[2ex]&\tan(-\alpha)=-\tan(\alpha)\\&\tan(\pi\pm\alpha)=\pm\tan(\alpha)\\&\tan\left(\frac{\pi}{2}\pm\alpha\right)=\mp\cot(\alpha)\end{aligned}\tag{8.1.22}$$

Or summarized as a table for only the simplest one:

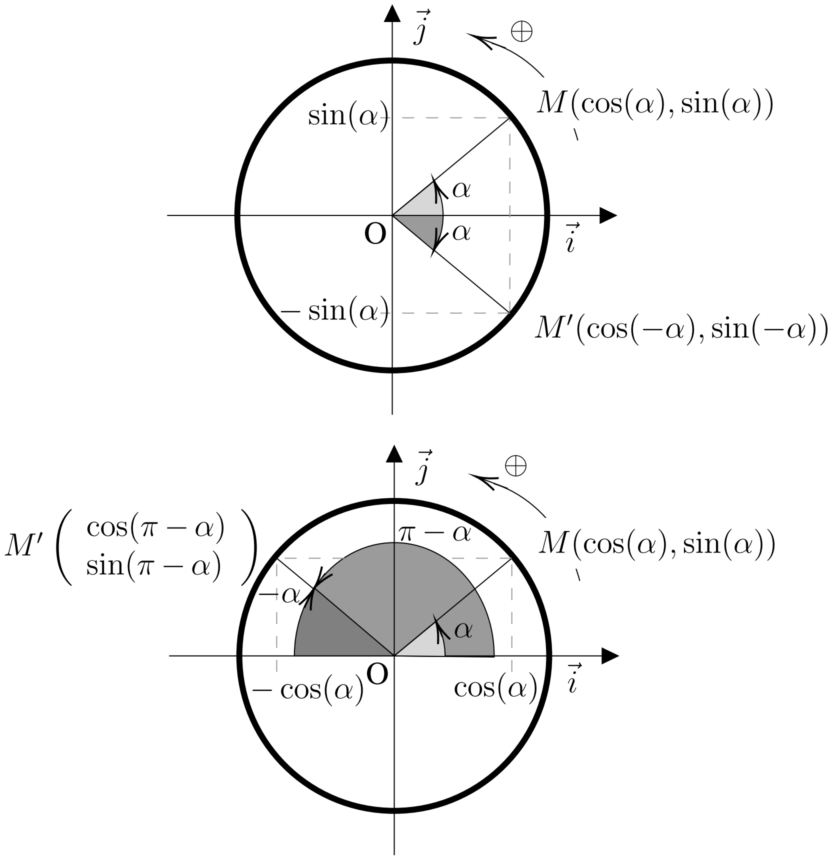
Trigonometric Functions	
Even Functions $f(-x)=f(x)$	**Odd Functions** $f(-x)=-f(x)$
$\cos(-x)=\cos(x)$ $\sec(-x)=\sec(x)$	$\sin(-x)=-\sin x$ $\csc(-x)=-\csc(x)$ $\tan(-x)=-\tan(x)$ $\cot(-x)=-\cot(x)$

Table 8.1: **Odd and even trigonometric functions**

Remark

The minus-plus sign "$\mp$" is generally used in conjunction with the "$\pm$" sign in a same relation. So when the first is at the "$+$" level, then the other one is at "$-$" level and conversely.

Here are the figures that summarize how to analyse some of these properties (for other relations, the method is the same):



$\vec{j}$

Table 8.2: Some identity angles and conventional trigonometric associated values table

Let us now introduce one last definition concerning circle trigonometric function relation that we will meet again in the sections of Wave Optics or during our study of Fourier transforms in the section of Sequences and Series which is the "sine cardinal":

$$\text{sinc}(x)=\frac{\sin(x)}{x} \tag{8.1.23}$$

represented by (with Maple™ 4.00b):

```
>with(plots):
>sinc:=sin(x)/x;
>plot([sinc(x)], x=-5*Pi..5*Pi, Sinc);
```

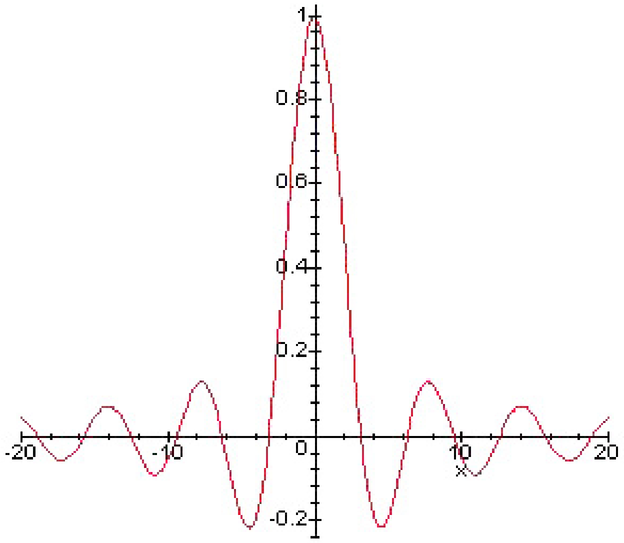

Figure 8.12: **2D plot of the sinc function in Maple™ 4.00b**

Or in a much better quality using TikZ:

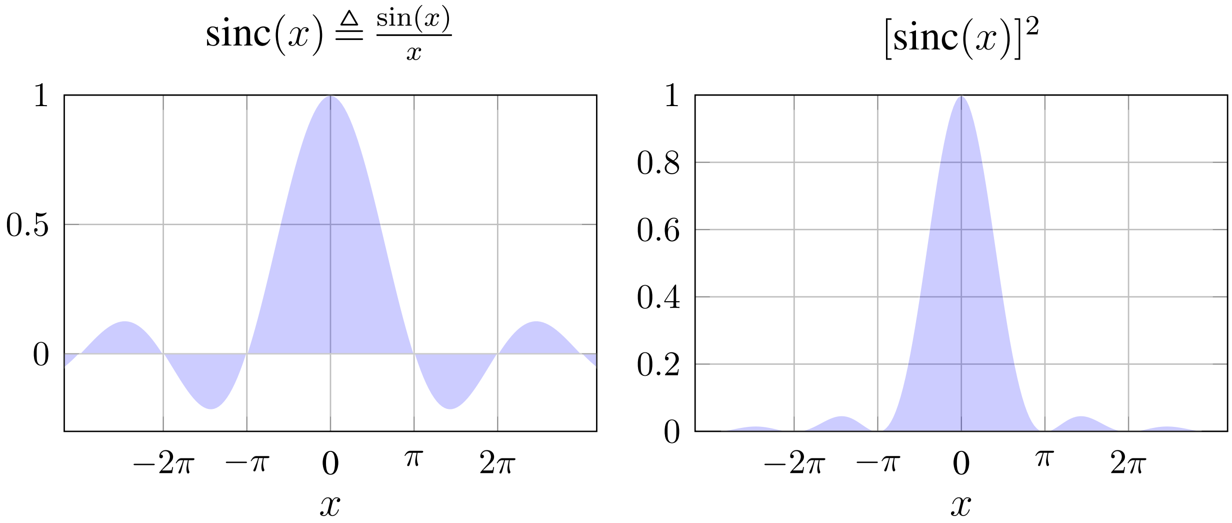

Figure 8.13: **Sine cardinal and its famous square equivalent (author: Jimmy Roussel)**

Even if engineers know very well the previous figures it is especially its pseudo-3D representation which is known by common peoples because often used for marketing reasons as reminiscent of a drop of water falling into water (figure made with Maple™ 4.00b) and it is always pretty to look at ...:

```
>plot3d(sin(sqrt(x^2+y^2))/(sqrt(x^2+y^2)),x=-20..20,y=-20..20);
```

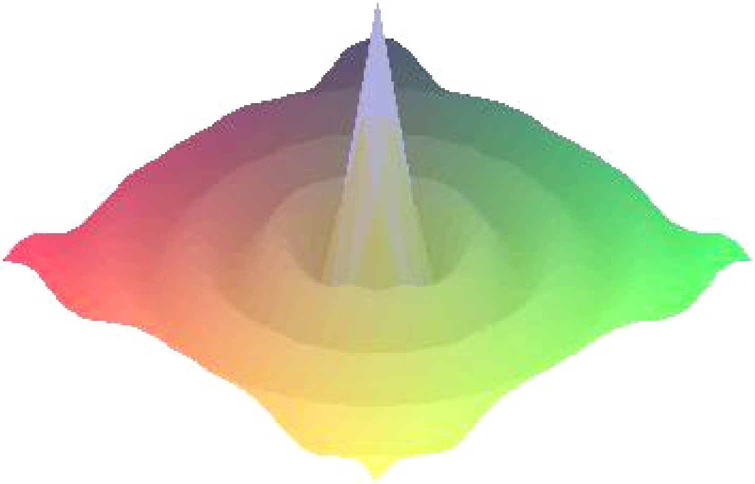

Figure 8.14: **Pseudo 3D plot of the sinc function in Maple™ 4.00b**

Or in a much better quality using TikZ:

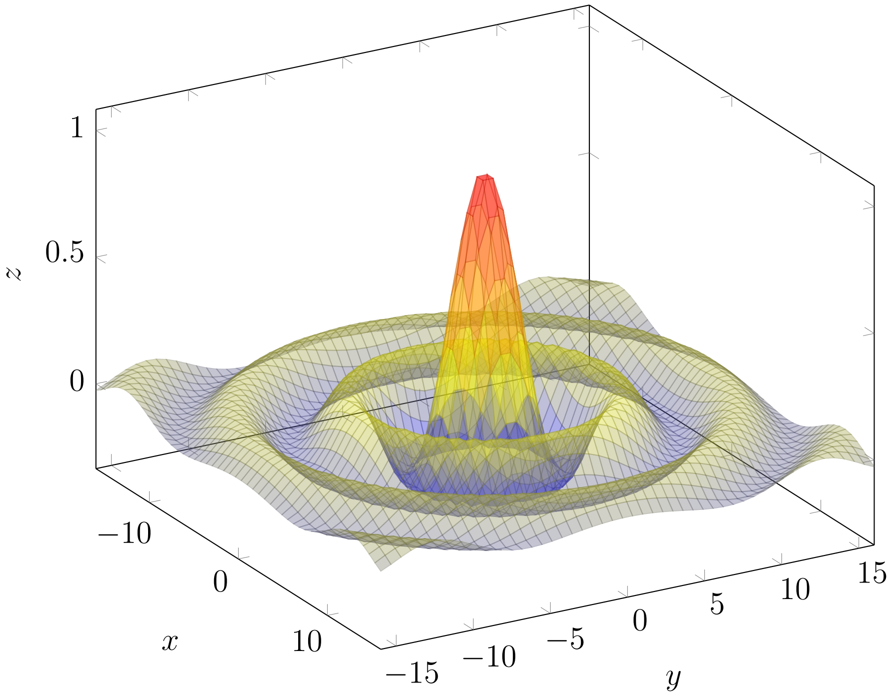

Figure 8.15: **Sine cardinal function with TikZ**

In either case, the value at $x = 0$ is defined to be the limiting value $\mathrm{sinc}(0) = 1$ that is really easy to prove using l'Hôpital's rule (see section Differential and Integral Calculus page 1461).

Keep in mind that the "sinc" function is especially important in signal processing and is the Fourier transform of a rectangular pulse and also in some Optics Phenomenon.

8.1.2.1 Remarkable trigonometric triangle identities

The drawing below will allow us to build relations that will help to solve equations involving trigonometric functions (all these relations are of primary importance in physics to simplify problem solving!).

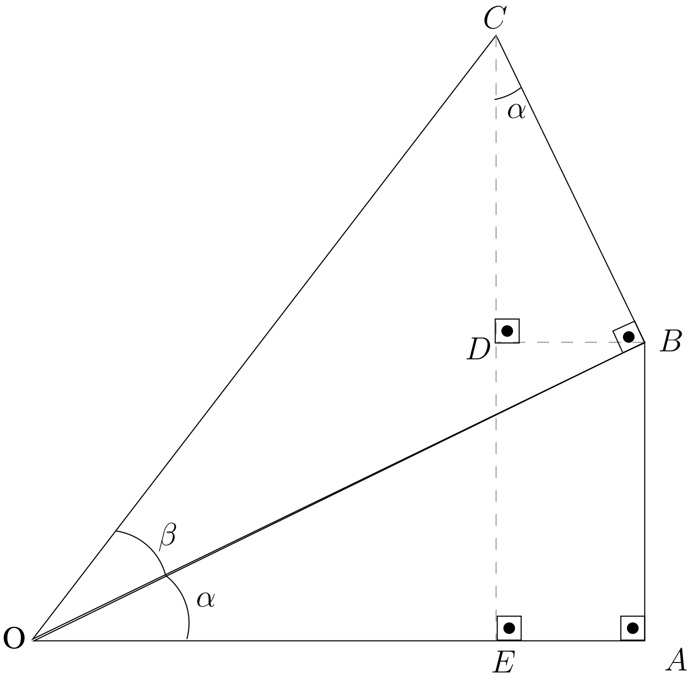

Figure 8.16: Basic construction for determining remarkable circle trigonometric identities for triangles

First we will note on the above figure the following relation:

$$\overline{DE}=\overline{AB} \tag{8.1.24}$$

Therefore:

$$\begin{aligned}\sin(\alpha+\beta)&=\frac{\overline{CD}+\overline{DE}}{\overline{\text{O}C}}=\frac{\overline{CD}}{\overline{\text{O}C}}+\frac{\overline{DE}}{\overline{\text{O}C}}=\frac{\overline{CD}}{\overline{\text{O}C}}\frac{\overline{CB}}{\overline{CB}}+\frac{\overline{DE}}{\overline{\text{O}C}}\frac{\overline{\text{O}B}}{\overline{\text{O}B}}\\&=\frac{\overline{CB}}{\overline{\text{O}C}}\frac{\overline{CD}}{\overline{CB}}+\frac{\overline{\text{O}B}}{\overline{\text{O}C}}\frac{\overline{AB}}{\overline{\text{O}B}}=\sin(\beta)\cos(\alpha)+\cos(\beta)\sin(\alpha)\end{aligned} \tag{8.1.25}$$

To resume:

$$\sin(\alpha+\beta)=\sin(\beta)\cos(\alpha)+\cos(\beta)\sin(\alpha) \tag{8.1.26}$$

Remark

We hesitated to put the main triangle identities in boxes (frames) but in fact all the results above and below are important and therefore everything will have been into boxes... So we apology to the reader if the absence of boxes (frames) disturbs.

This implies trivially if $\alpha=\beta$:

$$\sin(2\alpha)=2\sin(\alpha)\cos(\alpha) \tag{8.1.27}$$

and:

$$\sin(\alpha-\beta)=\sin(\alpha+(-\beta))=\sin(\alpha)\cos(-\beta)+\cos(\alpha)\sin(-\beta) \tag{8.1.28}$$

Therefore:

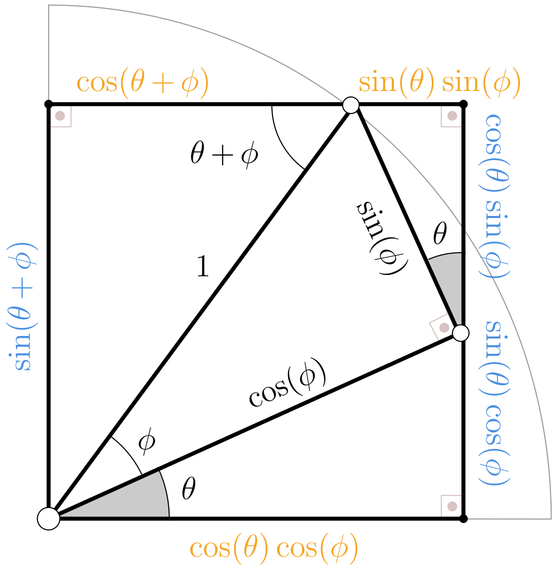
$$\sin(\alpha-\beta)=\sin(\alpha)\cos(\beta)-\cos(\alpha)\sin(\beta) \tag{8.1.29}$$

We also have:

$$\begin{aligned}\sin\left([\alpha+\beta]+\frac{\pi}{2}\right)&=\cos(\alpha+\beta)=\sin(\alpha)\cos\left(\beta+\frac{\pi}{2}\right)+\cos(\alpha)\sin\left(\beta+\frac{\pi}{2}\right)\\&=\sin(\alpha)(-\sin(\beta))+\cos(\alpha)\cos(\beta)\end{aligned} \tag{8.1.30}$$

Therefore:

$$\cos(\alpha+\beta)=\cos(\alpha)\cos(\beta)-\sin(\alpha)\sin(\beta) \tag{8.1.31}$$



$\cos(\theta+\phi)$
$\sin(\theta)\sin(\phi)$
$\theta+\phi$
$\cos(\theta)\sin(\phi)$
$\sin(\phi)$
θ
1
$\sin(\theta+\phi)$
$\sin(\theta)\cos(\phi)$
$\cos(\phi)$
ϕ
θ
$\cos(\theta)\cos(\phi)$

$$\begin{gathered}\sin(\theta+\phi)=\sin(\theta)\cos(\phi)+\cos(\theta)\sin(\phi)\\\cos(\theta+\phi)=\cos(\theta)\cos(\phi)-\sin(\theta)\sin(\phi)\end{gathered}$$

This implies trivially if $\alpha=\beta$:

$$\cos(2\alpha)=\cos^2(\alpha)-\sin^2(\alpha) \tag{8.1.32}$$

With the already proven identity $\cos^2(\alpha)+\sin^2(\alpha)=1$ we also get the very important following relations:

$$\cos(2\alpha)=\cos^2(\alpha)-\sin^2(\alpha)=1-2\sin^2(\alpha)=2\cos^2(\alpha)-1 \tag{8.1.33}$$

Relations with which we get very easily relations that seems to be named "Carnot's Formula":

$$\sin^2(\alpha)=\frac{1-\cos(2\alpha)}{2}\qquad\cos^2(\alpha)=\frac{1+\cos(2\alpha)}{2} \tag{8.1.34}$$

and:

$$\cos(\alpha-\beta)=\cos(\alpha+(-\beta))=\cos(\alpha)\cos(-\beta)-\sin(\alpha)\sin(\beta) \tag{8.1.35}$$

We also have:

$$\tan(\alpha+\beta)=\frac{\sin(\alpha+\beta)}{\cos(\alpha+\beta)}=\frac{\dfrac{\sin(\alpha)\cos(\beta)}{\cos(\alpha)\cos(\beta)}+\dfrac{\cos(\alpha)\sin(\beta)}{\cos(\alpha)\cos(\beta)}}{\dfrac{\cos(\alpha)\cos(\beta)}{\cos(\alpha)\cos(\beta)}-\dfrac{\sin(\alpha)\sin(\beta)}{\cos(\alpha)\cos(\beta)}}=\frac{\tan(\alpha)+\tan(\beta)}{1-\tan(\alpha)\tan(\beta)} \tag{8.1.36}$$

This, to get the relation:

$$\tan(\alpha+\beta)=\frac{\tan(\alpha)+\tan(\beta)}{1-\tan(\alpha)\tan(\beta)} \tag{8.1.37}$$

which implies when $\alpha=\beta$:

$$\tan(2\alpha)=\frac{2\tan(\alpha)}{1-\tan^2(\alpha)} \tag{8.1.38}$$

and obviously:

$$\tan(\alpha-\beta)=\tan(\alpha+(-\beta))=\frac{\tan(\alpha)+\tan(-\beta)}{1-\tan(\alpha)\tan(-\beta)}=\frac{\tan(\alpha)-\tan(\beta)}{1+\tan(\alpha)\tan(\beta)} \tag{8.1.39}$$

Therefore to summarize:

$$\tan(\alpha\pm\beta)=\frac{\tan(\alpha)\pm\tan(\beta)}{1\pm\tan(\alpha)\tan(\beta)} \tag{8.1.40}$$

We also get trivially (ask us if you have problems!) from previous relations (we do a little mixing and we shake...):

$$\begin{aligned}\tan^2(\alpha)&=1-\frac{2\tan(\alpha)}{\tan(2\alpha)}\\ \tan^2(\alpha)&=\frac{1-\cos(2\alpha)}{1+\cos(2\alpha)}\end{aligned} \tag{8.1.41}$$

We also have using above results:

$$\sin(2\alpha)=2\sin(\alpha)\frac{\cos(\alpha)}{\cos(\alpha)}\cos(\alpha)=2\tan(\alpha)\cos^2(\alpha) \tag{8.1.42}$$

using the relation proved far above :

$$\frac{1}{\cos^2(\alpha)}=\tan^2(\alpha)+1 \tag{8.1.43}$$

Therefore:

$$\sin(2\alpha)=2\tan(\alpha)\cos^2(\alpha)=\frac{2\tan(\alpha)}{\tan^2(\alpha)+1}\Leftrightarrow\sin(\alpha)=\frac{2\tan\left(\dfrac{\alpha}{2}\right)}{\tan^2\left(\dfrac{\alpha}{2}\right)+1} \tag{8.1.44}$$

Exactly similarly we get (ask us if you need the details):

$$\cos(2\alpha)=\cos^2(\alpha)-\sin^2(\alpha)=\cos^2(\alpha)(1-\tan^2(\alpha)) \tag{8.1.45}$$

Using always:

$$\frac{1}{\cos^2(\alpha)}=\tan^2(\alpha)+1 \tag{8.1.46}$$

Therefore:

$$\cos(2\alpha)=\cos^2(\alpha)(1-\tan^2(\alpha))=\frac{1-\tan^2(\alpha)}{\tan^2(\alpha)+1}\Leftrightarrow\cos(\alpha)=\frac{1-\tan^2\left(\dfrac{\alpha}{2}\right)}{\tan^2\left(\dfrac{\alpha}{2}\right)+1} \tag{8.1.47}$$

Now let us determine additional trigonometric formulas that seems to be name "Simpson's Formula" or "trigonometric addition formulas" which express the sum of sine and / or cosine in product of sine and / or cosine.

Given the identities already previously proved:

$$\begin{aligned}&(1)\quad \cos(\alpha+\beta)=\cos(\alpha)\cos(\beta)-\sin(\alpha)\sin(\beta)\\&(2)\quad \cos(\alpha-\beta)=\cos(\alpha)\cos(\beta)+\sin(\alpha)\sin(\beta)\end{aligned} \tag{8.1.48}$$

That can also be summarized as:

$$\cos(\alpha\pm\beta)=\cos(\alpha)\cos(\beta)\mp\sin(\alpha)\sin(\beta) \tag{8.1.49}$$

Let us put $\alpha+\beta=p$ and $\alpha-\beta=q$ and this also give us:

$$\alpha=\frac{p+q}{2}\qquad\beta=\frac{p-q}{2} \tag{8.1.50}$$

We get by summing (1) and (2):

$$\cos(p)+\cos(q)=2\cos\left(\frac{p+q}{2}\right)\cos\left(\frac{p-q}{2}\right) \tag{8.1.51}$$

and by subtracting:

$$\cos(p)-\cos(q)=2\sin\left(\frac{p+q}{2}\right)\sin\left(\frac{p-q}{2}\right) \tag{8.1.52}$$

In the same way we but starting from:

$$\begin{aligned}&(1)\quad \sin(\alpha+\beta)=\sin(\alpha)\cos(\beta)+\cos(\alpha)\sin(\beta)\\&(2)\quad \sin(\alpha-\beta)=\sin(\alpha)\cos(\beta)-\cos(\alpha)\sin(\beta)\end{aligned} \tag{8.1.53}$$

That can also be summarized as:

$$\sin(\alpha\pm\beta)=\sin(\alpha)\cos(\beta)\pm\cos(\alpha)\sin(\beta) \tag{8.1.54}$$

We get first by summing:

$$\sin(p)+\sin(q)=2\sin\left(\frac{p+q}{2}\right)\cos\left(\frac{p-q}{2}\right) \tag{8.1.55}$$

and by subtracting:

$$\sin(p)-\sin(q)=2\sin\left(\frac{p-q}{2}\right)\cos\left(\frac{p+q}{2}\right) \tag{8.1.56}$$

and re-injecting the angles we easily (normally but if you have difficulties tell us!) fall back on the following "Simpson's inverse formulas":

$$\begin{aligned}\cos(\alpha)\cos(\beta)&=\frac{1}{2}\left(\cos(\alpha+\beta)+\cos(\alpha-\beta)\right)\\ \sin(\alpha)\sin(\beta)&=\frac{1}{2}\left(\cos(\alpha-\beta)-\cos(\alpha+\beta)\right)\\ \sin(\alpha)\cos(\beta)&=\frac{1}{2}\left(\sin(\alpha+\beta)+\sin(\alpha-\beta)\right)\end{aligned} \tag{8.1.57}$$

We also have starting from:

$$\sin(\alpha+\beta)=\sin(\alpha)\cos(\beta)+\cos(\alpha)\sin(\beta) \tag{8.1.58}$$

and we divide by $\cos(\alpha)\cos(\beta)$, to get:

$$\frac{\sin(\alpha+\beta)}{\cos(\alpha)\cos(\beta)}=\frac{\sin(\alpha)\cos(\beta)+\cos(\alpha)\sin(\beta)}{\cos(\alpha)\cos(\beta)}=\frac{\sin(\alpha)}{\cos(\alpha)}+\frac{\sin(\beta)}{\cos(\beta)}=\tan(\alpha)+\tan(\beta) \tag{8.1.59}$$

And exactly in the same way we get:

$$\frac{\sin(\alpha-\beta)}{\cos(\alpha)\cos(\beta)}=\frac{\sin(\alpha)\cos(\beta)-\cos(\alpha)\sin(\beta)}{\cos(\alpha)\cos(\beta)}=\frac{\sin(\alpha)}{\cos(\alpha)}-\frac{\sin(\beta)}{\cos(\beta)}=\tan(\alpha)-\tan(\beta) \tag{8.1.60}$$

All these relations will help us in our study of general physics (especially in the section of Wave Mechanics and therefore in the sections of Electrodynamics and Acoustics) and particularly in the case of integral calculations or superposition of waves.

Remarque

To summarize (this may help...), the following equalities demonstrated previously:

$$\begin{aligned}\cos(p)+\cos(q)&=2\cos\left(\frac{p+q}{2}\right)\cos\left(\frac{p-q}{2}\right)\\ \cos(p)-\cos(q)&=2\sin\left(\frac{p+q}{2}\right)\sin\left(\frac{p-q}{2}\right)\\ \sin(p)+\sin(q)&=2\sin\left(\frac{p+q}{2}\right)\cos\left(\frac{p-q}{2}\right)\\ \sin(p)-\sin(q)&=2\sin\left(\frac{p-q}{2}\right)\cos\left(\frac{p+q}{2}\right)\\ \tan(\alpha)+\tan(\beta)&=\frac{\sin(\alpha+\beta)}{\cos(\alpha)\cos(\beta)}\\ \tan(\alpha)-\tan(\beta)&=\frac{\sin(\alpha-\beta)}{\cos(\alpha)\cos(\beta)}\end{aligned} \tag{8.1.61}$$

are therefore named "Simpson's formulas".

Let us also derive the following identity that will be useful to us in the section of Differential and Integral Calculus:

$$\begin{aligned}\tan\left(x+\frac{\pi}{2}\right)&=\frac{\sin\left(x+\frac{\pi}{2}\right)}{\cos\left(x+\frac{\pi}{2}\right)}=\frac{\sin x\cos\left(\frac{\pi}{2}\right)+\cos x\sin\left(\frac{\pi}{2}\right)}{\cos x\cos\left(\frac{\pi}{2}\right)-\sin x\sin\left(\frac{\pi}{2}\right)}\\&=\frac{0+\cos(x)}{0-\sin(x)}=-\frac{\cos(x)}{\sin(x)}=-\cot(x)\end{aligned}\tag{8.1.62}$$

and respectively:

$$\cot(x)=-\tan\left(x-\frac{\pi}{2}\right)\tag{8.1.63}$$

We also have this identity that will be useful to us in the section of Astronomy:

$$\begin{aligned}\tan^2(x)-\cot^2(x)&=\frac{\sin^2(x)}{\cos^2(x)}-\frac{\cos^2(x)}{\sin^2(x)}\\&=\frac{\sin^4(x)-\cos^4(x)}{\cos^2(x)\sin^2(x)}\\&=\frac{\left(\sin^2(x)+\cos^2(x)\right)\left(\sin^2(x)-\cos^2(x)\right)}{(\cos(x)\sin(x))^2}\\&=\frac{(1)(-\cos(2x))}{\frac{1}{4}\sin^2(2x)}\\&=-4\frac{\cos(2x)}{\sin^2(2x)}\end{aligned}\tag{8.1.64}$$

8.1.2.1.1 Laws of Cosines (cosine rule)

Let us prove now the cosine theorem that will be very useful to us in the sections of Geometry, Cosmology, Electrodynamics and Mechanics.

Theorem 8.1. In any triangle, the square of one of the three sides is equal to the sum of the squares of the two others reduced by the product of these two sides by the cosine of the angle between them:

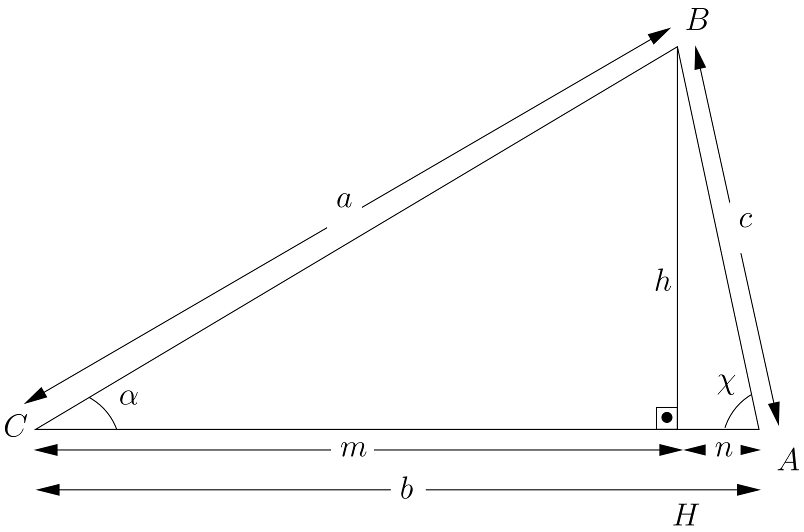


Figure 8.17: **Construction for the proof of the law of cosines**

Proof 8.1.1. One possible proof has the following path by using the Pythagorean theorem:

$$\begin{array}{r}a^2=h^2+m^2\\ -c^2=h^2+n^2\\ \hline a^2-c^2=m^2-n^2\\ a^2-c^2=(m+n)(m-n)\\ a^2-c^2=b(b-2n)=b^2-2nb\end{array} \tag{8.1.65}$$

But in the ABH triangle, rectangle in H, we have the relation $n/c=\cos(\chi)$ seen above therefore:

$$a^2-c^2=b(b-2n)=b^2-2nb=b^2-2bc\cos(\chi) \tag{8.1.66}$$

So we get one of the relations of the "cosine theorem":

$$\boxed{a^2=b^2+c^2-2bc\cos(\chi)} \tag{8.1.67}$$

By circular permutation, we get the other two known relations of the cosine theorem.

■ Q.E.D.

Remark

The cosine theorem is sometimes named "Al-Kashi's formula". And you can note that if a is the hypotenuse and its opposite angle a right angle such that $\cos(\chi)$ is zero, so we fall back on the Pythagorean theorem. Here's why we sometimes name the Al-Kashi's formula: "generalized Pythagorean formula".

An interesting case for applying the cosine theorem is to determine the distance l between a point b on the circumference of the circle and a point a situated inside the circle depending on the direction (angle) in which the eye is directed:

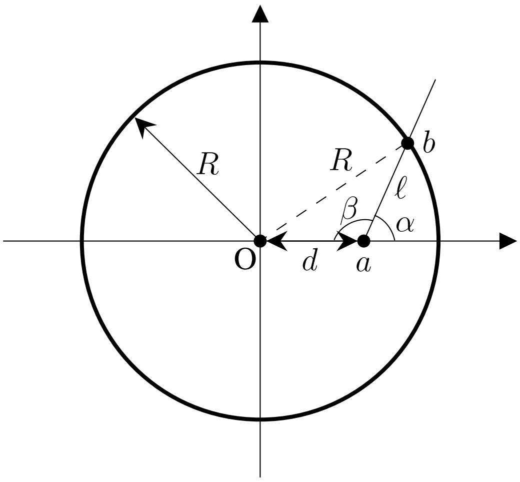

Figure 8.18: **Distance from a point inside a circle at its circumference**

We can therefore apply the cosine theorem that gives us (knowing d, R and β):

$$R^2=d^2+l^2-2dl\cos(\beta) \tag{8.1.68}$$

Therefore:

$$l^2-(2d\cos(\beta))l-(R^2-d^2)=0 \tag{8.1.69}$$

It is therefore an equation of the second degree whose discriminant is (see section Calculus page 1383):

$$\Delta^2=(2d\cos(\beta))^2+4(R^2-d^2) \tag{8.1.70}$$

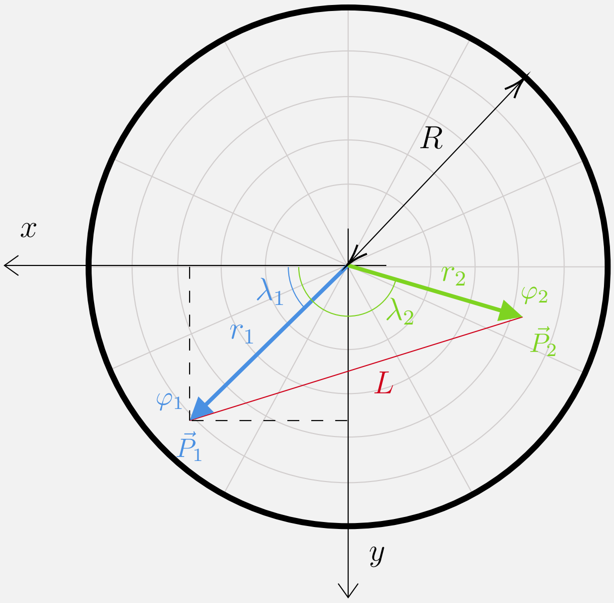
and whose two solutions are (see section Calculus page 1383):

$$l_{1,2}=\frac{2d\cos(\beta)\pm\sqrt{(2d\cos(\beta))^2+4(R^2-d^2)}}{2}=d\cos(\beta)\pm\sqrt{(d\cos(\beta))^2+(R^2-d^2)} \tag{8.1.71}$$

We will also see an important application in the section of Geometric Shapes to calculate the area of any triangle (Heron's formula) page 2898.

Remark

A funny application of the law of cosines is also the flat Earth joke. Indeed, in this joke the Earth is represented by a disc of radius R as seen from the top as:



R
x
y
λ_1
r_1
φ_1
$\vec{P}_1$
r_2
λ_2
φ_2
$\vec{P}_2$
L

where $\vec{P}_1$ and $\vec{P}_2$ are two localization of this flat Earth. Then from the law of cosines, we get:

$$L = R \cdot \sqrt{r_1^2 + {r_2}^2 - 2 \cdot r_1 \cdot r_2 \cdot \cos(\Delta\lambda)} \tag{8.1.72}$$

with:

$$r_1 = \left(1 - \frac{\varphi_1}{90^\circ}\right) \quad r_2 = \left(1 - \frac{\varphi_2}{90^\circ}\right) \quad \Delta\lambda = \lambda_2 - \lambda_1 \tag{8.1.73}$$

8.1.2.1.2 Laws of Sines (sine rule)

Consider the below triangle for whom we represent the two heights:

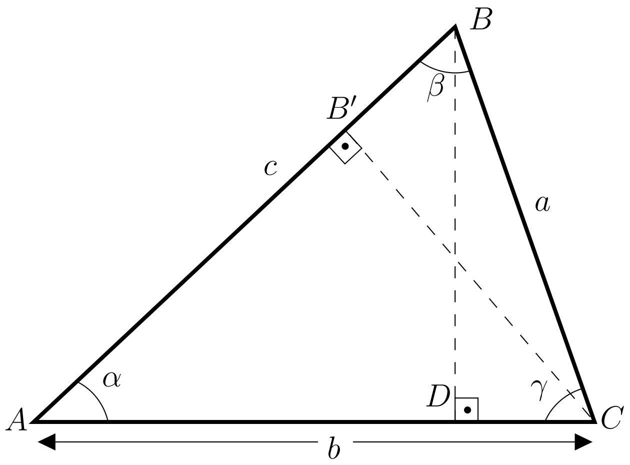


Figure 8.19: **Construction for the proof of the law of sines**

In the triangle above we have the relations:

$$\sin(\alpha)=\frac{\overline{DB}}{c}\qquad \sin(\gamma)=\frac{\overline{DB}}{a}\tag{8.1.74}$$

which leads us to the expression:

$$\overline{DB}=c\sin(\alpha)=a\sin(\gamma)\tag{8.1.75}$$

Therefore:

$$\frac{a}{\sin(\alpha)}=\frac{c}{\sin(\gamma)}\tag{8.1.76}$$

By similar reasoning we have:

$$\sin(\alpha)=\frac{\overline{CB'}}{b}\qquad \sin(\beta)=\frac{\overline{c}}{a}\tag{8.1.77}$$

That gives in the same way:

$$\frac{a}{\sin(\alpha)}=\frac{b}{\sin(\beta)}\tag{8.1.78}$$

All combined provides us the "sine theorem", the most beautiful example of application in this textbook is certainly the determination of the Lagrange points L4 and L5 in the section Astronomy:

$$\boxed{\frac{a}{\sin(\alpha)}=\frac{b}{\sin(\beta)}=\frac{c}{\sin(\gamma)}}\tag{8.1.79}$$

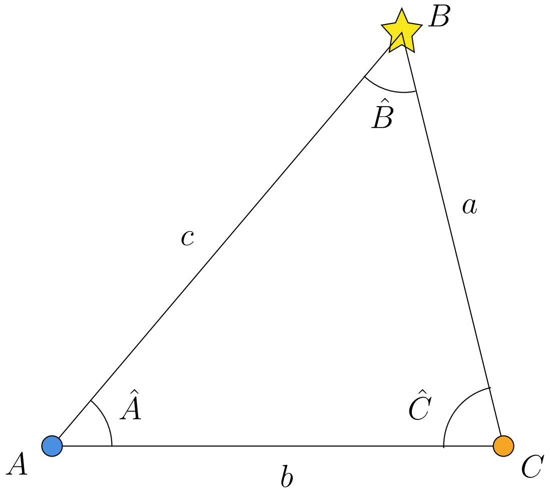
Obviously, there is not here all the existing trigonometric circle relations as we have already said, but at least the most important you need to know to find we you study physical systems.

The law of sines in famously know for its application to "triangulation"! In trigonometry and geometry, triangulation is the process of determining the location of a point by forming triangles to the point from known points. The properties used for triangulation are:

- The sum of the angles of a triangle, equal to π radians (180°)
- The law of sines

If we denote a the side opposite the angle $\hat{A}$ and c the side opposite the angle $\hat{C}$, we express the law of sines as follows:

$$\frac{a}{\sin(\hat{A})}=\frac{b}{\sin(\hat{B})}=\frac{c}{\sin(\hat{C})} \tag{8.1.80}$$



Hence:

$$\begin{aligned}AB=c=\frac{b\sin(\hat{C})}{\sin(\hat{B})}\\ CB=a=\frac{b\sin(\hat{A})}{\sin(\hat{B})}\end{aligned} \tag{8.1.81}$$

We obviously have:

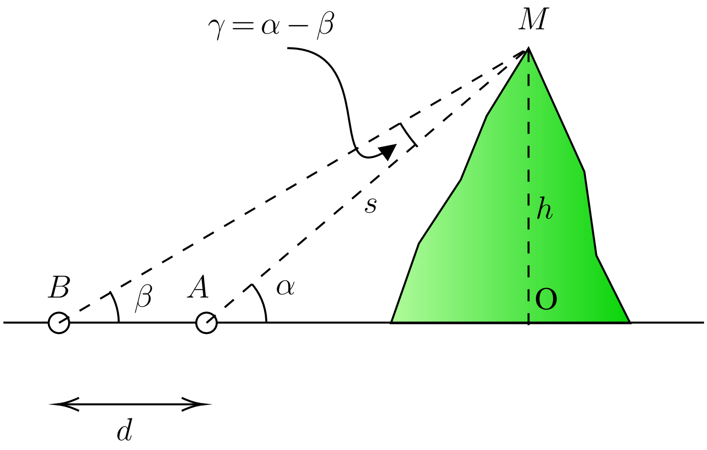
$$\hat{C}=180^\circ-\hat{A}-\hat{B} \tag{8.1.82}$$

✍**Example:**

Abū Rayḥān Al-Bīrūnī, a pioneering Muslim scientist, figured out a truly remarkable and ingenious method to calculate the radius of the Earth (and subsequently its circumference) in the 111th century (holocene calendar) different from that of Eratosthenes (that used another method 13 centuries before). This method was very simple yet accurate, requiring just four measurements in all to be taken and then applying a trigonometric relation to arrive at the solution.

To carry out his method Biruni only needed an astrolabe, a suitable mountain with a flat horizon in front of it so that the angle of depression of the horizon could be accurately measured and basic knowledge of trigonometry.

Let us consider the figure below depicting the scenario:



Considering the right-angled triangle OMA, the mountain height h and the (unknown) slope height s are related obviously by:

$$h=s\cdot\sin(\alpha) \tag{8.1.83}$$

Considering angles in triangle AMB, we easily see that $\gamma=\alpha-\beta$. Then, applying the sine rule to AMB, we get:

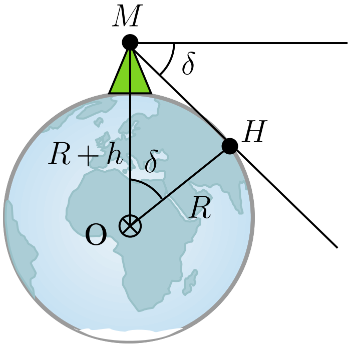
$$\frac{s}{\sin(\beta)}=\frac{d}{\sin(\alpha-\beta)} \tag{8.1.84}$$

Combining the two relations above and using the trigonometric identities proved earlier we easily get using the Simpson's relation also proved earlier above:

$$h=\left(\frac{\sin(\alpha)\sin(\beta)}{\sin(\alpha-\beta)}\right)d=\frac{\tan(\alpha)\cos(\alpha)\tan(\beta)\cos(\beta)}{\sin(\alpha-\beta)}d=\left(\frac{\tan(\alpha)\tan(\beta)}{\tan(\alpha)-\tan(\beta)}\right)d \tag{8.1.85}$$

This is the relationship that Al Biruni used to calculate the height of the mountain. The input values $\{\alpha,\beta,d\}$ can all be obtained with good precision so that, provided the tangents of angles can be evaluated accurately, an excellent estimate of the height h can be made. Indeed, the relation has been used in surveying up to the present day!

We now describe how al-Biruni used the mountain height to estimate the size of the Earth. The single additional measurement he required was the dip angle δ of the horizon as viewed from the mountain top (M in the figure below):



It is clear that the angle MOH is equal to δ. It is also clear from the figure that $\cos(\delta) = R/(R+h)$. This implies:

$$R = \frac{\cos(\delta)}{1-\cos(\delta)}h \tag{8.1.86}$$

which gives us a formula for Earth radius R. Provided that he could evaluate the cosine of a small angle δ, al-Biruni could use this formula to obtain R from h and δ.

8.1.3 Hyperbolic Trigonometry

We have shown in the section of Functional Analysis that any function $f(x)$ can be divided into an odd and even function as:

$$f(x)=\frac{f(x)-f(-x)}{2}+\frac{f(x)+f(-x)}{2} \tag{8.1.87}$$

Thus, for the function $f(x)=e^x$, we get:

$$e^x=\frac{e^x-e^{-x}}{2}+\frac{e^x+e^{-x}}{2} \tag{8.1.88}$$

Remember that in our study of complex numbers (see section Numbers page 252) we proved the following Euler formulas:

$$\cos(\phi)=\frac{e^{\mathrm{i}\phi}+e^{-\mathrm{i}\phi}}{2} \qquad \sin(x)=\frac{e^{\mathrm{i}\phi}-e^{-\mathrm{i}\phi}}{2\mathrm{i}} \tag{8.1.89}$$

and we talked about the fact that even if ϕ should be most of time be in $\mathbb{R}$, it can also be in $\mathbb{C}$ and therefore we generalize the definition of the sine and cosine by analogy with the hyperbolic sine and cosine (we will demonstrate the origin of this term later below) by:

$$\boxed{\cosh(z)=\frac{e^z+e^{-z}}{2} \qquad \sinh(z)=\frac{e^z-e^{-z}}{2}} \tag{8.1.90}$$

where $z\in\mathbb{C}$. Therefore we can also obviously define:

$$\tanh(z)=\frac{\sinh(z)}{\cosh(z)} \tag{8.1.91}$$

And so on... like for circle trigonometry.

By the way, the reader can notice that:

$$\cos(z)=\cosh(\mathrm{i}z) \quad \cosh(z)=\cos(\mathrm{i}z) \tag{8.1.92}$$

We can therefore write:

$$e^z=\cosh(z)+\sinh(z) \tag{8.1.93}$$

relation that we can again put in analogy with:

$$e^{\mathrm{i}x}=\cos(x)+\mathrm{i}\sin(x) \tag{8.1.94}$$

Interestingly, we can now work with complex angles in trigonometry!!! Indeed, if we put $a+ib$ then we have:

$$e^{a+ib}=\cosh(a+ib)+\sinh(a+ib) \tag{8.1.95}$$

But as we know (see section Numbers page 1353):

$$e^{a+\mathrm{i}b}=e^a e^{\mathrm{i}b}=re^{\mathrm{i}b}=r(\cos(b)+\mathrm{i}\sin(b)) \tag{8.1.96}$$

Therefore we can write the following equality:

$$e^a\cos(b)+e^a\mathrm{i}\sin(b)=\cosh(a+\mathrm{i}b)+\sinh(a+\mathrm{i}b) \tag{8.1.97}$$

Therefore the hyperbolic trigonometric function of a complex angle exists and the image is also a complex number. We can see abusively hyperbolic trigonometry as a kind of generalization of trigonometry circle with real and complex angles.

As opposed to the circle trigonometry where we have proved that:

$$\sin^2(\alpha)+\cos^2(\alpha)=1 \tag{8.1.98}$$

In hyperbolic trigonometry we have:

$$\sinh^2(z)-\cosh^2(z)=1 \tag{8.1.99}$$

The proof is easy:

$$\begin{aligned}\cosh^2(z)&=\left(\frac{e^z-e^{-z}}{2}\right)^2=\frac{e^{2z}-2e^ze^{-z}+e^{-2z}}{4}=\frac{1}{2}+\frac{e^{2z}+e^{-2z}}{4}\\&=1-\frac{1}{2}+\frac{e^{2z}+e^{-2z}}{4}=1+\frac{e^{2z}-2+e^{-2z}}{4}=1+\frac{e^{2z}-2e^ze^{-z}+e^{-2z}}{4}\\&=1+\left(\frac{e^z+e^{-z}}{2}\right)^2=1+\sinh^2(z)\end{aligned} \tag{8.1.100}$$

By rearranging we get:

$$\sinh^2(z)-\cosh^2(z)=1 \tag{8.1.101}$$

Before we prove why this is named "hyperbolic trigonometric" let us see some important identities that we will use in various sections of this textbook.

First we will look for a closed form of the reciprocal hyperbolic sine and cosine functions. For this purpose remember that:

$$y:=\cosh(z)=\frac{e^z+e^{-z}}{2} \tag{8.1.102}$$

and that the search for the inverse function is always to isolate the variable (in this case: z).

Therefore:

$$2y-e^{-z}-e^z=2\cosh(z)-e^{-z}-e^z=0 \tag{8.1.103}$$

That is to say (multiplying by $-e^z$):

$$(e^z)^2-2ye^z+1=0 \tag{8.1.104}$$

by solving the polynomial this second degree polynomial on e^z we get:

$$e^z_{1,2}=\frac{2y\pm\sqrt{4y^2-4}}{2}=y\pm\sqrt{y^2-1} \tag{8.1.105}$$

As $e^z > 0$ we must reject the solution with the sign "$-$" (yes! otherwise with a $z \in \mathbb{R}$ you could have a negative e^z). It comes then:

$$e^z = y + \sqrt{y^2 - 1} \tag{8.1.106}$$

Therefore:

$$z = \ln\left(y + \sqrt{y^2 - 1}\right) \tag{8.1.107}$$

Using the same for:

$$y := \sinh(z) = \frac{e^z + e^{-z}}{2} \tag{8.1.108}$$

Therefore:

$$2y + e^{-z} - e^z = 2\sinh(z) + e^{-z} - e^z = 0 \tag{8.1.109}$$

That is to say (multiplying by $-e^z$):

$$(e^z)^2 - 2ye^z - 1 = 0 \tag{8.1.110}$$

by solving the polynomial this second degree polynomial on e^z we get:

$$e^z_{1,2} = \frac{2y \pm \sqrt{4y^2 + 4}}{2} = y \pm \sqrt{y^2 + 1} \tag{8.1.111}$$

As $e^z > 0$ we must reject the solution with the sign "-" (yes! otherwise with a $z \in \mathbb{R}$ you could have a negative e^z). It comes then:

$$e^z = y + \sqrt{y^2 + 1} \tag{8.1.112}$$

Therefore:

$$z = \ln\left(y + \sqrt{y^2 + 1}\right) \tag{8.1.113}$$

Finally :

$$\begin{aligned} z = \operatorname{arccosh}(y) \quad &= \ln\left(y + \sqrt{y^2 - 1}\right) \\ z = \operatorname{arcsinh}(y) \quad &= \ln\left(y + \sqrt{y^2 + 1}\right) \end{aligned} \tag{8.1.114}$$

Caution! Following the authors arccosh and arcsinh are denoted by argcosh, argsinh or $\cosh^{-1}, \sinh^{-1}$ (the two last notations are confusing with the corresponding inverse hyperbolic function!).

To study now a simple important geometric representation of that stuff let us now write:

$$\begin{aligned} \cos(\alpha) = X \qquad & \sin(\alpha) = Y \\ \cosh(z) = X' \qquad & \sinh(z) = Y' \end{aligned} \tag{8.1.115}$$

With a restriction $\alpha, z \in \mathbb{R}$ we have:

$$\begin{aligned} X &= [-1,1] \qquad Y = [-1,1] \\ X' &= [1,+\infty] \qquad Y' =]-\infty,+\infty[\end{aligned} \tag{8.1.116}$$

This can be represented as follow:

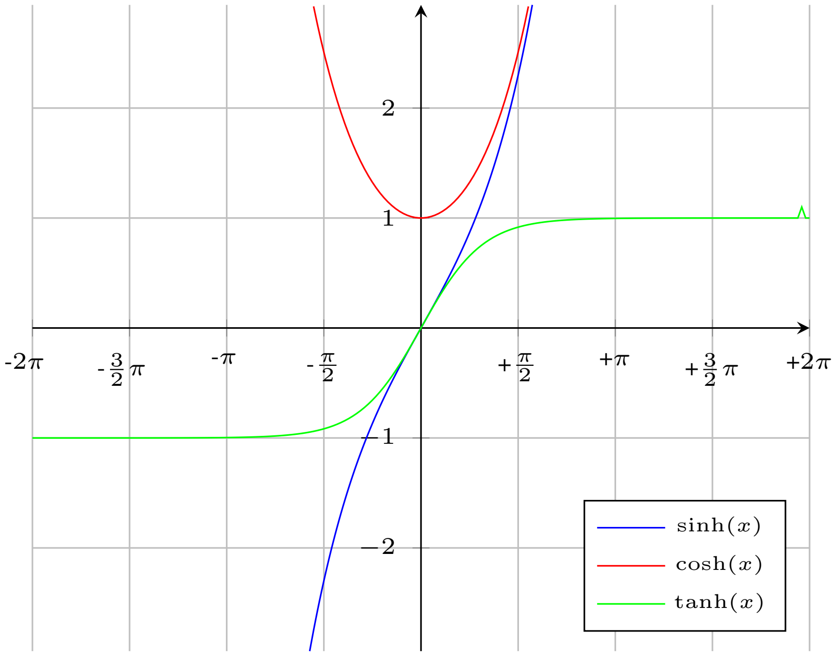


Figure 8.20: **Hyperbolic functions domain**

With this new notation, we have:

$$\begin{aligned} \cos^2(\alpha)+\sin^2(\alpha) &= X^2+Y^2 = 1 \\ \cosh^2(z)+\sinh^2(z) &= X'^2-Y'^2 = 1 \end{aligned} \tag{8.1.117}$$

But as we shall see in our study on conical in the section of Analytical Geometry:

1. The first of these two relations is for the entire given domain of definition, a circle of unit radius centered on the origin. The reader will note that it is curious enough for circle trigonometry to get a circle ☺
2. The second of these two relations is for the entire domain of a definition, an equilateral hyperbola oriented along the X axis whose apex is $S(1,0)$ and of focus $F(\sqrt{2},0)$. The reader will note again that he is curious enough for hyperbolic trigonometry to get a hyperbola ☺

For the second case this takes us to have the possibility to represent the two main hyperbolic trigonometric functions as:

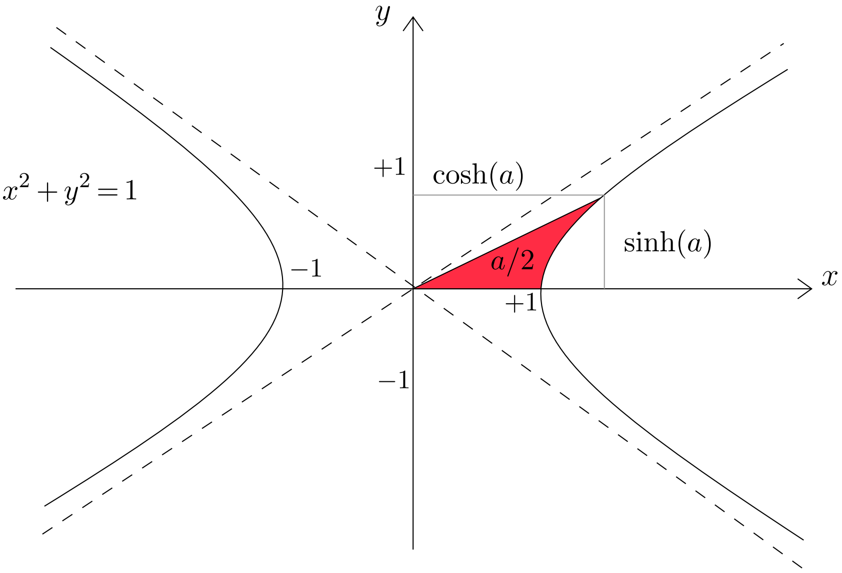

Figure 8.21: Equivalence of hyperbolic functions and hyperbola (source: Wikipedia)

This figure is very interesting because as we will prove it now, from the calculation of the red area $a/2$, where a is assimilated to a "hyperbolic angle", we can also define the hyperbolic trigonometric functions.

Let us denote by x and y the abscissa and ordinate of the red triangle (by imagining this is full a triangle). We therefore have (see section Geometric Shapes page 2896) therefore for its area (base multiplied by high divided by 2):

$$A_{\text{tr}}=\frac{xy}{2} \tag{8.1.118}$$

But we see that we have to subtract a part of an area under the hyperbola of equation $X^2-Y^2=1$. That is to say of equation:

$$Y=\sqrt{X^2-1}:=\sqrt{t^2-1} \tag{8.1.119}$$

And the area to subtract is therefore given by:

$$A_{\text{hyp}}=\int\limits_1^x\sqrt{t^2-1}\mathrm{d}t \tag{8.1.120}$$

Therefore the red area is given by:

$$A=A_{\text{tr}}-A_{\text{hyp}}=\frac{xy}{2}-\int\limits_1^x\sqrt{t^2-1}\mathrm{d}t \tag{8.1.121}$$

Using the primitive proved in the section of Differential and Integral Calculus (see page 1534), we get:

$$A=\frac{xy}{2}-\left(\frac{t}{2}\sqrt{t^2-1}-\frac{1}{2}\ln\left(t+\sqrt{t^2-1}\right)\right)\Bigg|_1^x \tag{8.1.122}$$

Therefore:

$$A=\frac{xy}{2}-\frac{x}{2}\sqrt{x^2-1}+\frac{1}{2}\ln\left(x+\sqrt{x^2-1}\right) \tag{8.1.123}$$

But we can rewrite this:

$$A=\frac{x\sqrt{x^2-1}}{2}-\frac{x}{2}\sqrt{x^2-1}-\frac{1}{2}\ln\left(x+\sqrt{x^2-1}\right):=\frac{a}{2} \tag{8.1.124}$$

Therefore:

$$a=x\sqrt{x^2-1}-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right) \tag{8.1.125}$$

Finally:

$$a=\ln\left(x+\sqrt{x^2-1}\right)=2A \tag{8.1.126}$$

We recognize here the first relation of the both that we proved a little sooner above if we put $z=a,y=x$:

$$\begin{aligned} z=\text{arccosh}(y) &=\ln\left(y+\sqrt{y^2-1}\right)\\ z=\text{arcsinh}(y) &=\ln\left(y+\sqrt{y^2+1}\right)\end{aligned} \tag{8.1.127}$$

So the interpretation is very interesting: the hyperbolic angle can be seen as the double of the red triangle surface (or if you prefer: the half of the hyperbolic angle is equal to the red surface)!

These two relations:

$$\begin{aligned}&\cos^2(\alpha)+\sin^2(\alpha)=X^2+Y^2=1\\ &\cosh^2(z)+\sinh^2(z)=X'^2-Y'^2=1\end{aligned} \tag{8.1.128}$$

should help, we hope to understand the origin of the name of the hyperbolic trigonometry and note that the study of hyperbolic trigonometry, is analogous to the study of circle trigonometry on the circle.

If we represent the trigonometric circle and the trigonometric hyperbole and we add some additional information, here is what we get:

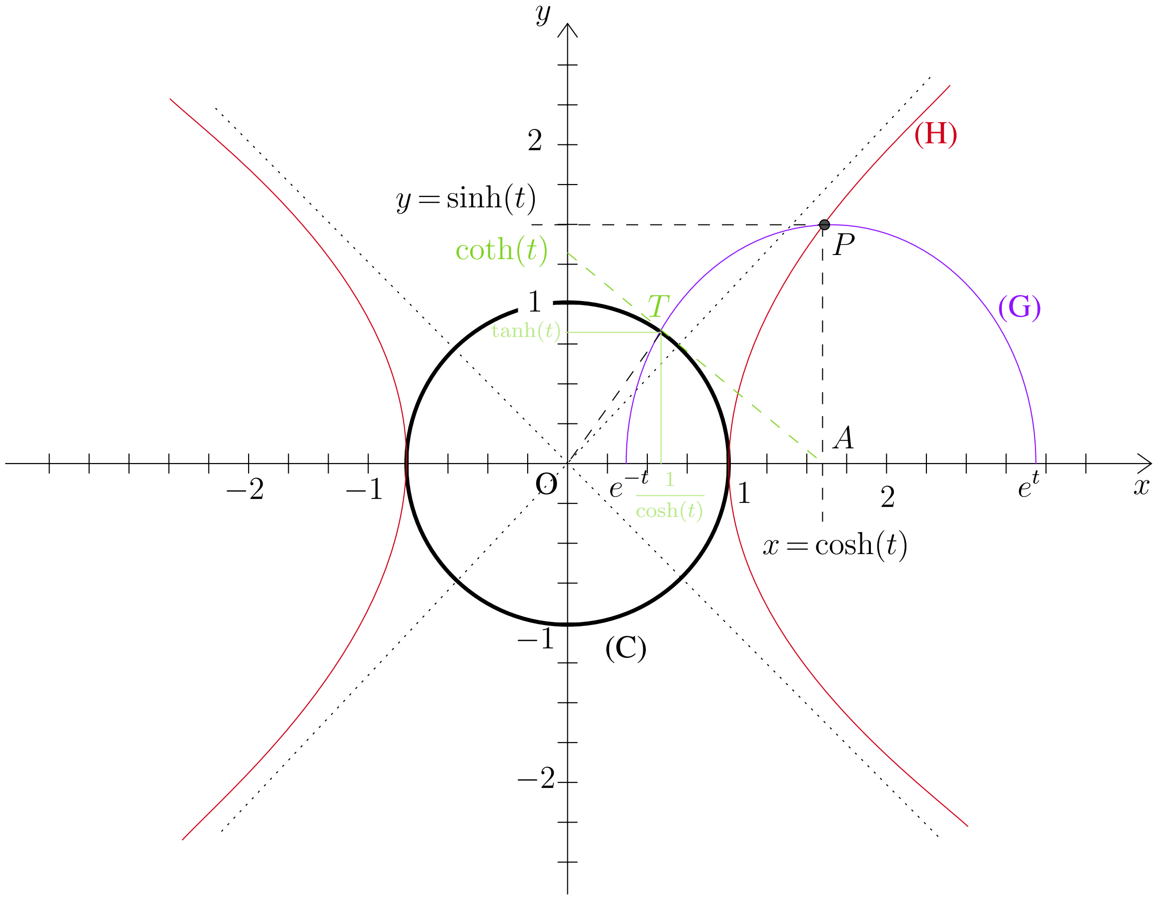

Figure 8.22: Visual definition of circle and hyperbolic trigonometric functions

Explanations:

To trace with the ruler and compass the point $P(x,y)$ of the hyperbole, we give ourself a x, that is to say the point $A(x,0)$. We draw the tangent to the circle (C) through $A(x,0)$ which gives us the tangent point T. We trace the circle (G) of center $A(x,0)$ and passing through T. This circle intersects the hyperbola at the point $P(x,y)$ perpendicular to the $A(x,0)$ to Ox.

We see appear on the figure several values of the hyperbolic functions corresponding to $x = \cosh(t), y = \sinh(t)$ but also $\tanh(t), \coth(t)$, etc. Among others, the circle (G) intersects the axis Ox in two points whose abscissas are e^t and e^{-t}.

If the reader wants to check thanks to the figure, it can control that in all points of the hyperbole, the relations (among others):

$$\cosh(t) = \frac{e^t + e^{-t}}{t} \qquad \sinh(t) = \frac{e^t - e^{-t}}{t} \qquad \cosh^2(t) - \sinh^2(t) = 1 \tag{8.1.129}$$

are always verified.

We get for the readers who wants to play with software using Maple™ 4.00b:

```
>plot([sinh(x),cosh(x),tanh(x)],x=-2*Pi..2*Pi,color=[red,black,blue]);
```

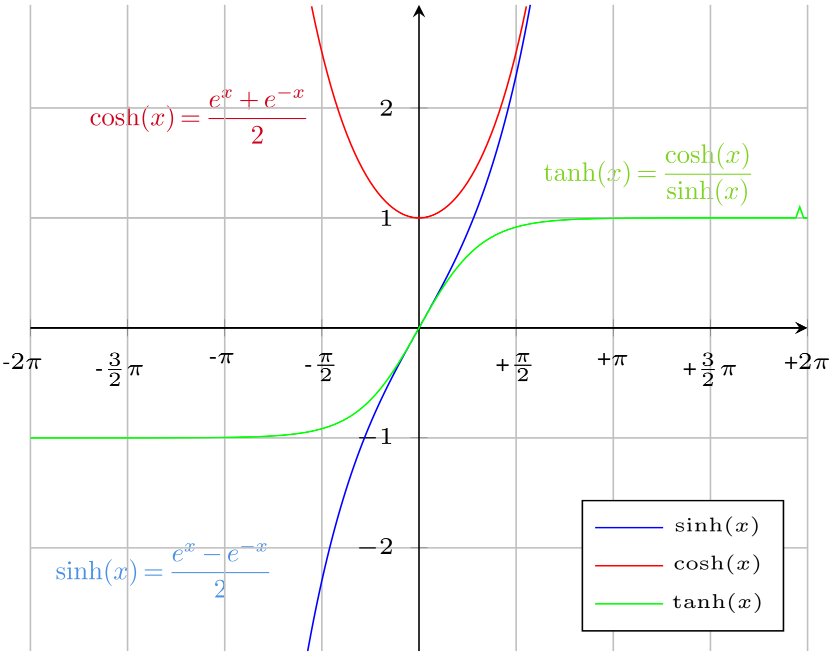

Figure 8.23: Visual definition of hyperbolic trigonometric

We will see again the $\cosh(x)$ in the section of Civil Engineering for example in the context of suspended cables. We also see again $\sinh(x)$ and $\tanh(x)$ as part of the study of gravity waves in the section of Marine and Weather Engineering.

8.1.3.1 Remarkable hyperbolic identities

The purpose now is as for the circle trigonometry to prove some remarkable identities but for hyperbolic trigonometry.

So we start with the definition:

$$\cosh(z)=\frac{e^z+e^{-z}}{2}\qquad \sinh(z)=\frac{e^z-e^{-z}}{2}\tag{8.1.130}$$

and:

$$\tanh(z)=\frac{\cosh(z)}{\sinh(z)}=\frac{e^z-e^{-z}}{e^z+e^{-z}}=\frac{e^{2z}-1}{e^{2z}+1}\qquad \coth(z)=\frac{1}{\tanh(z)}=\frac{\sinh(z)}{\cosh(z)}=\frac{e^{2z}+1}{e^{2z}-1}\tag{8.1.131}$$

From these definitions and using the basic algebra operations we can determine the following outstanding relations (this is much easier than determining the remarkable relations of circle trigonometry, so unless requested we give most of these relations without proof).

First let us begin with the very easiest one:

$$\begin{aligned}&\cosh(z)+\sinh(z)=e^z &&\cosh(z)-\sinh(z)=e^{-z}\\&\cosh(-z)=\cosh(z)&&\sinh(-z)=-\sinh(z)\\&\tanh(-z)=-\tanh(z)&&\coth(-z)=-\coth(z)\end{aligned}\tag{8.1.132}$$

We also have:

$$\cosh^2(z) = \frac{1}{1-\tanh^2(z)} = \frac{\cosh(2z)+1}{2} \qquad \sinh^2(z) = \frac{\tanh^2(z)}{1-\tanh^2(z)} = \frac{\cosh(2z)-1}{2} \tag{8.1.133}$$

And we have the addition relations:

$$\begin{aligned}\cosh(a+b) &= \cosh(a)\cosh(b)+\sinh(a)\sinh(b)\\ \cosh(a-b) &= \cosh(a)\cosh(b)-\sinh(a)\sinh(b)\\ \sinh(a+b) &= \sinh(a)\cosh(b)+\cosh(a)\sinh(b)\\ \sinh(a-b) &= \sinh(a)\cosh(b)-\cosh(a)\sinh(b)\end{aligned} \tag{8.1.134}$$

Following the request of a reader, let us prove the first and third above relations.

For the first:

$$\begin{aligned}&\cosh(a)\cosh(b)+\sinh(a)\sinh(b) = \frac{e^a+e^{-a}}{2}\frac{e^b+e^{-b}}{2}+\frac{e^a-e^{-a}}{2}\frac{e^b-e^{-b}}{2}\\ &= \frac{1}{4}\left[\left(e^{a+b}+e^{a-b}+e^{-a+b}+e^{-a-b}\right)+\left(e^{a+b}-e^{a-b}-e^{-a+b}+e^{-a-b}\right)\right]\\ &= \frac{1}{4}\left[\left(2e^{a+b}+2e^{-a-b}\right)\right] = \frac{1}{2}\left[\left(e^{a+b}+e^{-(a+b)}\right)\right] = \cosh(a+b)\end{aligned} \tag{8.1.135}$$

and for the third:

$$\begin{aligned}&\sinh(a)\cosh(b)+\cosh(a)\sinh(b) = \frac{e^a-e^{-a}}{2}\frac{e^b+e^{-b}}{2}+\frac{e^a+e^{-a}}{2}\frac{e^b-e^{-b}}{2}\\ &= \frac{1}{4}\left[\left(e^{a+b}+e^{a-b}-e^{-a+b}-e^{-a-b}\right)+\left(e^{a+b}-e^{a-b}+e^{-a+b}-e^{-a-b}\right)\right]\\ &= \frac{1}{4}\left[\left(2e^{a+b}-2e^{-a-b}\right)\right] = \frac{1}{2}\left[\left(e^{a+b}-e^{-(a+b)}\right)\right] = \sinh(a+b)\end{aligned} \tag{8.1.136}$$

Also let us mention other remarkable identities (once again don't hesitate to request us the detail proof if you need help):

$$\begin{aligned}\cosh(a)+\cosh(b) &= 2\cosh\left(\frac{a+b}{2}\right)\cosh\left(\frac{a-b}{2}\right)\\ \cosh(a)-\cosh(b) &= 2\sinh\left(\frac{a+b}{2}\right)\sinh\left(\frac{a-b}{2}\right)\\ \sinh(a)+\sinh(b) &= 2\sinh\left(\frac{a+b}{2}\right)\cosh\left(\frac{a-b}{2}\right)\\ \sinh(a)-\sinh(b) &= 2\cosh\left(\frac{a+b}{2}\right)\sinh\left(\frac{a-b}{2}\right)\end{aligned} \tag{8.1.137}$$

and finally (we stop here because we don't need anything else to study the other chapters and sections of this textbook):

$$\begin{aligned}
\tanh(a+b) &= \frac{\tanh(a)+\tanh(b)}{1+\tanh(a)\tanh(b)}\\
\tanh(a-b) &= \frac{\tanh(a)-\tanh(b)}{1-\tanh(a)\tanh(b)}\\
\tanh(a)+\tanh(b) &= \frac{\sinh(a+b)}{\cosh(a)\cosh(b)}\\
\tanh(a)-\tanh(b) &= \frac{\sinh(a-b)}{\cosh(a)\cosh(b)}
\end{aligned} \tag{8.1.138}$$

8.1.4 Spherical Trigonometry

The aim of spherical trigonometry is to determine remarkable relations between the angles and sides of projected forms (also named "geodetic forms" because following the curvature of space) on the surface of a sphere. To determine these relations, we will look at the special case of a sphere of radius unity and to the relations between the sides of a spherical triangle (planar elementary surface) and the various existing angles (because this is used a lot in spherical triangulation!). We will see that the results are completely independent of the radius of the sphere.

Consider the figure in which is located a geodesic triangle with vertices A,B,C of respective opening angles $\hat{A},\hat{B},\hat{C}$ and opposite sides a,b,c and three unit vectors $\vec{i},\vec{j},\vec{k}$ such as $\vec{i}\perp\vec{k},\vec{j}\perp\vec{k}$ and that the end of $\vec{k}$ is merged with the vertices A:

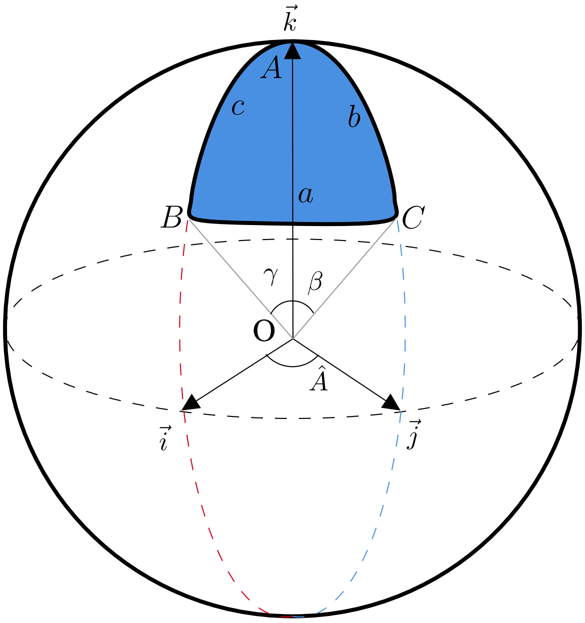

Figure 8.24: Construction to introduce the spherical geometry

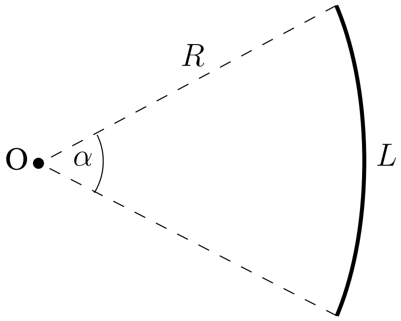
The angle between points B and C, denoted by α, could not be shown in the diagram above because of lack of space.

Let us recall that the perimeter of a unit circle on the sphere of radius unity is obviously $P=2\pi R$ (see section Euclidean Geometry page 2620). The perimeter of the circle as a function of the opening angle of the latter being given by (relation very often used in physics !!!):

$$\boxed{L=2\pi R\frac{\alpha}{2\pi}=R\alpha} \tag{8.1.139}$$



If the circle is of radius $R=1$ (as is the case for our sphere), the calculation of the arc length is simplified and becomes:

$$L=\alpha \tag{8.1.140}$$

We will keep this constraint of a unitary radius subsequently to simplify the expressions we'll get later on.

Consequently regarding the points on our sphere; the sides of the triangle are given by:

$$a=\alpha, b=\beta, c=\gamma \tag{8.1.141}$$

Now consider the scalar product (see section Vector Calculus page 1821):

$$\overrightarrow{\text{O}B}\circ\overrightarrow{\text{O}C}=\|\overrightarrow{\text{O}B}\|\|\overrightarrow{\text{O}C}\|\cos(\alpha) \tag{8.1.142}$$

and as $\overrightarrow{\text{O}B}=\overrightarrow{\text{O}C}$ (unit radius) we have:

$$\|\overrightarrow{\text{O}B}\|\|\overrightarrow{\text{O}C}\|\cos(\alpha)=\cos(\alpha)=\cos(a)=\overrightarrow{\text{O}B}\circ\overrightarrow{\text{O}C} \tag{8.1.143}$$

If we decompose the two vectors $\overrightarrow{\text{O}B}$ and $\overrightarrow{\text{O}C}$ vectors on the orthonormal vectors we have:

$$\begin{aligned}\overrightarrow{\text{O}B}&=\cos(\gamma)\vec{k}+\sin(\gamma)\vec{i}\\ \overrightarrow{\text{O}C}&=\cos(\beta)\vec{k}+\sin(\beta)\vec{j}\end{aligned} \tag{8.1.144}$$

This gives us:

$$\cos(a)=\overrightarrow{\text{O}B}\circ\overrightarrow{\text{O}C}=\left[\cos(\gamma)\vec{k}+\sin(\gamma)\vec{i}\right]\circ\left[\cos(\beta)\vec{k}+\sin(\beta)\vec{j}\right] \tag{8.1.145}$$

giving (distributive property of scalar product):

$$\cos(a)=\cos(\gamma)\cos(\beta)\vec{k}\circ\vec{k}+\cos(\gamma)\sin(\beta)\vec{k}\circ\vec{j}+\sin(\gamma)\cos(\beta)\vec{i}\circ\vec{k}+\sin(\gamma)\sin(\beta)\vec{i}\circ\vec{j} \tag{8.1.146}$$

As $\vec{k}\circ\vec{k}=1$ and $\vec{k}\circ\vec{i}=\vec{k}\circ\vec{j}=0$ the above relation reduces to:

$$\cos(a)=\cos(\gamma)\cos(\beta)+\sin(\gamma)\sin(\beta)\vec{i}\circ\vec{j} \tag{8.1.147}$$

And as:

$$\vec{i}\circ\vec{j}=\cos(\hat{A}) \tag{8.1.148}$$

We get:

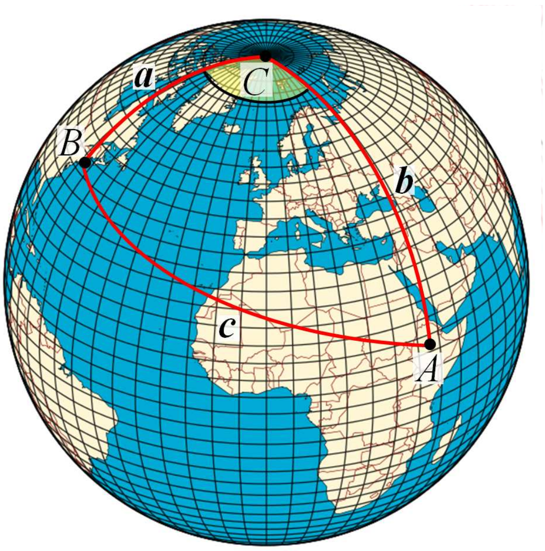
$$\cos(a)=\cos(\gamma)\cos(\beta)+\sin(\gamma)\sin(\beta)\cos(\hat{A}) \tag{8.1.149}$$

relation named "fundamental relation" or "cosine formula" that we can therefore as well write (because of the unitary radius assumption):

$$\boxed{\cos(a)=\cos(c)\cos(b)+\sin(c)\sin(b)\cos(\hat{A})} \tag{8.1.150}$$

✍**Example:**

On the globe below, Boston (B) and Addis Ababa (A) are plotted as the vertices of a spherical triangle with apex at the North Pole (C). Boston is at latitude $42°19'$ North which means edge a is subtended by a central angle of $90°-42°19'\approx 47.68°$.



Similarly Addis Ababa, latitude $9°03'$ North, gives the angle subtending edge b as about $80.95°$. And angle C is the sum of the longitudes: $71°05'\,\mathrm{W}+38°42'\,\mathrm{E}\approx 109.78°$. So the great circle distance c from B to A is given approximately by:

$$\cos^{-1}\left(\cos\left(48°\right)\cos\left(81°\right)+\sin\left(48°\right)\sin\left(81°\right)\cos\left(110°\right)\right) \tag{8.1.151}$$

which is about $98°=98\cdot 60$ nautical miles (1 nautical mile $=1$ minute of great circle arc), or about $10,900$ [km].

Also often rearranged as following (especially in statistics to introduce the partial correlation coefficient):

$$\cos(\hat{A})=\frac{\cos(a)-\cos(c)\cos(b)}{\sin(c)\sin(b)} \tag{8.1.152}$$

The latter relation is invariant by circular permutation of the variables $a,b,c,\hat{A}$. It is also interesting to note before we continue that if the spherical triangle has right angle at A, the previous relation simplifies to:

$$\cos(a)=\cos(c)\cos(b) \tag{8.1.153}$$

and if the triangle is sufficiently small relative to the radius and we make a second order Taylor expansion (see section Sequences and Series page 1696) near 0 for each of the terms we get:

$$\left(1-\frac{a^2}{2}\right)=\left(1-\frac{c^2}{2}\right)\left(1-\frac{b^2}{2}\right) \tag{8.1.154}$$

Therefore:

$$\left(1-\frac{a^2}{2}\right)=1-\frac{c^2}{2}-\frac{b^2}{2}+\underbrace{\frac{c^2b^2}{2}}_{\rightarrow 0} \tag{8.1.155}$$

After simplification:

$$a^2=b^2+c^2 \tag{8.1.156}$$

we find back the Pythagorean theorem (see section Euclidean Geometry page 2609). Therefore:

$$\cos(a)=\cos(c)\cos(b) \tag{8.1.157}$$

is the spherical geometry (non-Euclidean geometry) equivalent of the Pythagorean theorem in plane geometry (Euclidean geometry)!!!

This parenthesis now closed, let's us go back on our main business. The sine of all angles being positive (as all angles are $[0,\pi]$), we can write:

$$\begin{aligned}\frac{\sin(\hat{A})}{\sin(a)}=\frac{\sqrt{1-\cos^2(\hat{A})}}{\sin(\hat{a})}&=\frac{\sqrt{1-\left(\dfrac{\cos(a)-\cos(b)\cos(c)}{\sin(b)\sin(c)}\right)^2}}{\sin(\hat{a})}\\&=\frac{\sqrt{(1-\cos^2(b))(1-\cos^2(c))-\cos^2(a)-\cos^2(b)\cos^2(c)+2\cos(a)\cos(b)\cos(c)}}{\sin(a)\sin(b)\sin(c)}\\&=\frac{1-\cos^2(a)-\cos^2(b)-\cos^2(c)+2\cos(a)\cos(b)\cos(c)}{\sin(a)\sin(b)\sin(c)}\end{aligned} \tag{8.1.158}$$

The latter relation is of course also invariant by circular permutation of the variables $a,b,c,\hat{A}$. So we get a remarkable relation of the spherical triangle, named "sines relations" or "sines formula" and given by:

$$\boxed{\frac{\sin(\hat{A})}{\sin(a)}=\frac{\sin(\hat{B})}{\sin(b)}=\frac{\sin(\hat{C})}{\sin(c)}} \tag{8.1.159}$$

As spherical trigonometry is often used for land trails, often with two very specific and orthogonal circles: the Earth's equator and a meridian or any parallel, this case is of particular interest! Therefore in the case of a right triangle in A we obviously get:

$$\frac{1}{\sin(a)}=\frac{\sin(\hat{B})}{\sin(b)}=\frac{\sin(\hat{C})}{\sin(c)} \tag{8.1.160}$$

All the relationships that we have determined so far allow us, in the case where $\hat{A}=\pi/2$ and $R=1$, to draw very interesting relationships for geophysics:

$$\begin{aligned}\sin(b)&=\sin(a)\sin(\hat{B})\\ \sin(c)&=\sin(a)\sin(\hat{C})\\ \cos(a)&=\cos(b)\cos(\hat{c})\\ \cos(\hat{C})&=\sin(\hat{B})\cos(c)\\ \cos(\hat{C})&=\sin(\hat{B})\cos(c)\\ \cos(\hat{B})&=\sin(c)\cos(b)\end{aligned}\tag{8.1.161}$$

For sure, we have not presented here all the relations or remarkable identities existing about spherical trigonometry, but at least the most important one that should be know to read the other sections of this textbook.

Remark

We define the "surplus" or "spherical excess" by the number:

$$E=\hat{A}+\hat{B}+\hat{C}-\pi\tag{8.1.162}$$

8.1.4.1 Girard's theorem

While we are at it, let us calculate a classic problem which is that of the area of a triangle on a sphere. Consider the following figure:

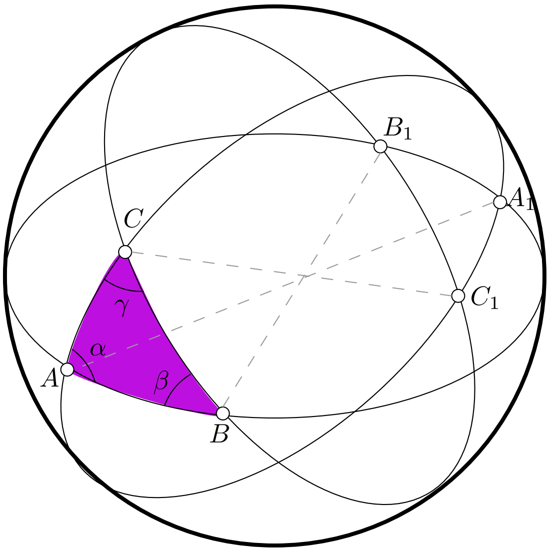


Figure 8.25: **Construction for the study of the surface of a spherical triangle**

If we extend the geodesic arcs $\overset{\frown}{AB}$ and $\overset{\frown}{AC}$ until A_1 we get a slice of a sphere whose surface is proportional to the angle α in A. If this angle was equal to 2π, we would have the whole sphere and the surface would be equal to $4\pi R^2$ (see section Geometric Shapes page 2964). As the angle is equal to α, the proportionality told us that S_1 is equal to:

$$S_1=\frac{\alpha}{2\pi}4\pi R^2=\alpha 2R^2 \tag{8.1.163}$$

Similarly, if we extend the arcs $\overset{\frown}{BC}$ and $\overset{\frown}{BA}$ up to B_1 and if we extend the arcs $\overset{\frown}{CA}$ and $\overset{\frown}{CB}$ until C_1, we get two slices with surfaces S_2 and S_3 are equal to:

$$S_2=\beta 2R^2 \quad S_3=\lambda 2R^2 \tag{8.1.164}$$

Now suppose we add these three areas:

$$S_1+S_2+S_3=2R^2(\alpha+\beta+\gamma) \tag{8.1.165}$$

we then get the half of the sphere $S_\odot$ (look to the figure to represent it yourself mentally) more two times the geodesic triangle area S in pink on the figure (as counted two times in excess).

We must subtract twice the blue triangle area to get the surface of the hemisphere:

$$\frac{S_\odot}{2}=2R^2(\alpha+\beta+\gamma)-2S \tag{8.1.166}$$

Therefore:

$$S_\odot=4R^2(\alpha+\beta+\gamma)-4S \tag{8.1.167}$$

as $S_\odot=4\pi R^2$, we get:

$$S=\frac{4R^2(\alpha+\beta+\gamma)-S_\odot}{4}=\frac{4R^2(\alpha+\beta+\gamma)-4\pi R^2}{4} \tag{8.1.168}$$

After simplification we deduce that the area S of the triangle ABC is:

$$S=R^2(\alpha+\beta+\gamma-\pi)=R^2\varepsilon \tag{8.1.169}$$

where ε is a solid angle (see below definition). That latter relation is sometimes named "Girard's theorem". More commonly written:

$$\boxed{\alpha+\beta+\gamma=\pi+\frac{S}{R^2}} \tag{8.1.170}$$

and $K=1/R^2$ is defined as the "curvature" (it indicates how much the geometry of the sphere deviates from the Euclidean plane geometry where $K=0$). On the basis of its definition K seems to depend on the radius of the sphere considered as a two dimensional manifold embedded in the ambient Euclidean space $\mathbb{R}^3$. The boxed relation above however tells us that the curvature K can be evaluated by just performing measures of angles and areas on the two-dimensional surface of the sphere. It follows that K has an intrinsic geometric meaning, that is independent of its embedding in the flat 3-dimensional space, since it can be computed by only using measures on the spherical surface.

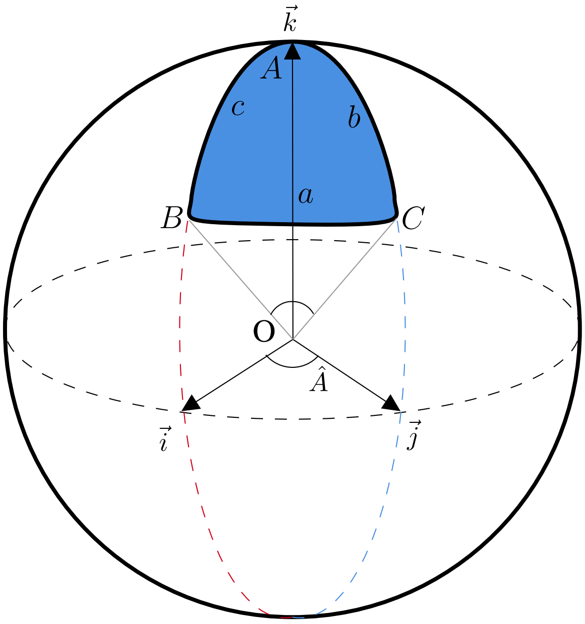
It is fairly simple to generalize this concept to other forms following the same philosophy (especially those composed of triangles...).

8.1.4.2 Four-parts formula

The "four-parts formulafour-parts formula" is a mathematical theorem in spherical trigonometry. It describes the relationship between four consecutive parts of a spherical triangle.

This formula is particularly useful in astronomy, geodesy, and navigation, where spherical triangles are commonly used. In this textbook we will use it to prove the property of a particular type of sundial!

Theorem 8.2. Let $\triangle ABC$ be a spherical triangle on the surface of a sphere whose center is O:



Let the sides a, b, c of $\triangle ABC$ be measured by the angles subtended at O, where a, b, c are opposite A, B, C respectively.

We have:

$$\cos(a)\cos(\hat{C}) = \sin(a)\cot(b) - \sin(\hat{C})\cot(\hat{B}) \tag{8.1.171}$$

That is:

$$\cos(\text{ inner side }) \cdot \cos(\text{ inner angle }) = \sin(\text{ inner side }) \cdot \cot(\text{ other side }) - \sin(\text{ inner angle }) \cdot \cot(\text{ other angle }) \tag{8.1.172}$$

This is known as the "four-parts formula", as it defines the relationship between each of four consecutive parts of $\triangle ABC$.

Proof 8.2.1. First we use the spherical cosine formula proved earlier above where we have for reminder:

$$\begin{aligned}\cos(b) &= \cos(a)\cos(c) + \sin(a)\sin(c)\cos(\hat{B})\\ \cos(c) &= \cos(b)\cos(a) + \sin(b)\sin(a)\cos(\hat{B})\end{aligned} \tag{8.1.173}$$

substituting for $\cos(c)$ we get:

$$\cos(b)=\cos(a)[\cos(b)\cos(a)+\sin(b)\sin(a)\cos(\hat{C})]+\sin(a)\sin(c)\cos(\hat{B}) \tag{8.1.174}$$

We distribute:

$$\cos(b)=\cos^2(a)\cos(b)+\cos(a)\sin(b)\sin(a)\cos(\hat{C})+\sin(a)\sin(c)\cos(\hat{B}) \tag{8.1.175}$$

We rearrange:

$$\cos(b)\left(1-\cos^2(a)\right)=\cos(a)\sin(b)\sin(a)\cos(\hat{C})+\sin(a)\sin(c)\cos(\hat{C}) \tag{8.1.176}$$

Hence using a simple trigonometric identity (sum of squares of sine and cosine):

$$\cos(b)\sin^2(a)=\cos(a)\sin(b)\sin(a)\cos(\hat{C})+\sin(a)\sin(c)\cos(\hat{B}) \tag{8.1.177}$$

dividing both sides by $\sin(a)\sin(b)$:

$$\cot(b)\sin(a)=\cos(a)\cos(\hat{C})+\frac{\sin(c)}{\sin(b)}\cos(\hat{B}) \tag{8.1.178}$$

Using the spherical law of since proved earlier above and given for reminder by:

$$\frac{\sin(\hat{A})}{\sin(a)}=\frac{\sin(\hat{B})}{\sin(b)}=\frac{\sin(\hat{C})}{\sin(c)} \tag{8.1.179}$$

we have:

$$\cot(b)\sin(a)=\cos(a)\cos(\hat{C})+\frac{\sin(\hat{C})}{\sin(\hat{B})}\cos(\hat{B}) \tag{8.1.180}$$

Rearranging and simplifying we get finally the "four-parts formula":

$$\boxed{\cos(a)\cos(\hat{C})=\sin(a)\cot(b)-\sin(\hat{C})\cot(\hat{B})} \tag{8.1.181}$$

■ Q.E.D.

8.1.5 Solid Angle

In spatial geometry, arise the problem of opening angle of a portion of the space (in extension to the so named "plane angle" that applies to $\mathbb{R}^2$). We define the "solid angle" by measuring the portion of space delimited by a conical surface of apex O and we express it in "steradian", given by the ratio (logical extension of the definition of the plane angle):

$$\Omega=\frac{S}{r^2} \tag{8.1.182}$$

S being the area of the cap cutted by a cone on a sphere of radius r.

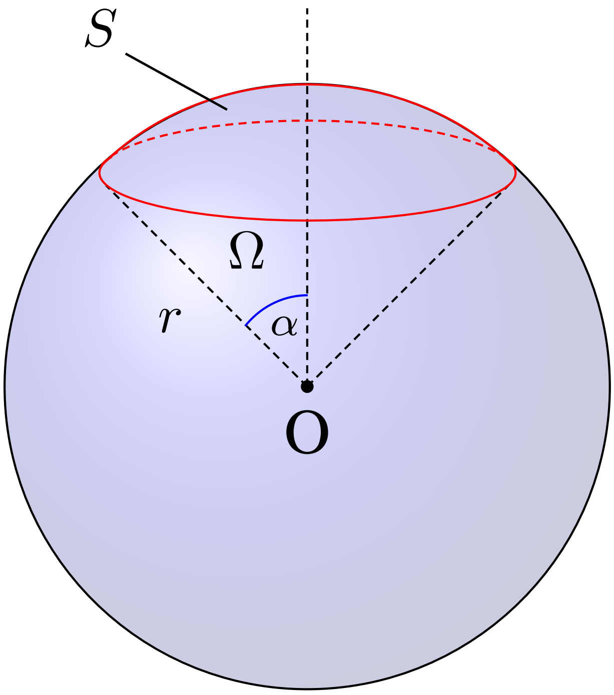


Figure 8.26: **Configuration for the definition of the solid angle**

If α is the half plane-angle of the cone, we get for this ratio (for calculation of the cap of a spherical surface see the section Geometric Shapes at page 2886):

$$\Omega = 2\pi(1-\cos(\alpha)) = 4\pi\sin^2\left(\frac{\alpha}{2}\right) \tag{8.1.183}$$

Hence we conclude that the total solid angle is by definition on the whole space:

$$\Omega_{\text{tot}} = 4\pi \tag{8.1.184}$$

We can also calculate the "elementary solid angle" as shown below:

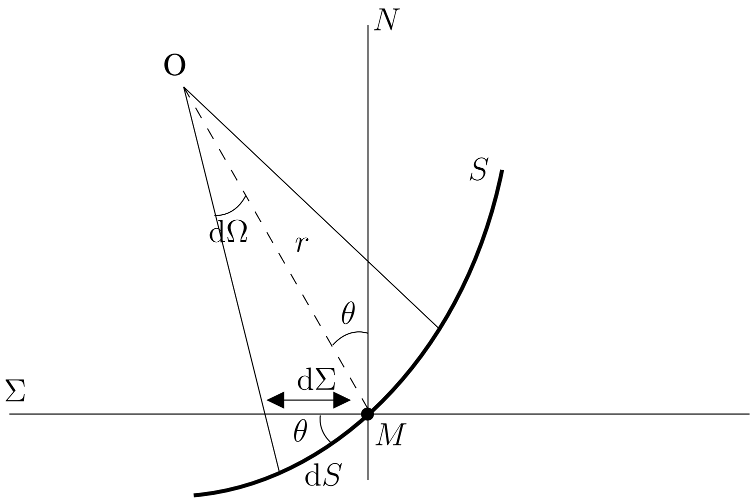

Figure 8.27: **Configuration for the definition of the elementary solid angle**

Given an elementary solid angle $\mathrm{d}\Omega$ and $\overline{\mathrm{O}M}$ the cone axis. We put:

$$\overline{\mathrm{O}M} = r \tag{8.1.185}$$

We consider any surface Σ passing through the point M. $\mathrm{d}\Omega$ cut on this surface a portion $\mathrm{d}\Sigma$.

If we draw the sphere $\mathcal{S}^2$ of center O and radius r, this solid angle cut on the sphere a cap of area $\mathrm{d}S$:

$$\mathrm{d}S = r^2\mathrm{d}\Omega \tag{8.1.186}$$

Given MN the normal to $\mathrm{d}\Sigma$ which make an angle θ with OM. We have assimilating $\mathrm{d}S$ and $\mathrm{d}\Sigma$ to portions of a plane:

$$\mathrm{d}S = \cos(\theta)\mathrm{d}\Sigma \tag{8.1.187}$$

Therefore:

$$\mathrm{d}\Omega = \frac{\mathrm{d}\Sigma\cos(\theta)}{2} \tag{8.1.188}$$

This concept of solid angle will be very useful especially in the field of theoretical physics that deals with the thermal radiation (see sections on Optics page 4339 and Thermodynamics page 3709 and Atomic Physics page 5100).

We can still calculate from the previous concepts, the elementary solid angle of revolution as presented in the figure below:

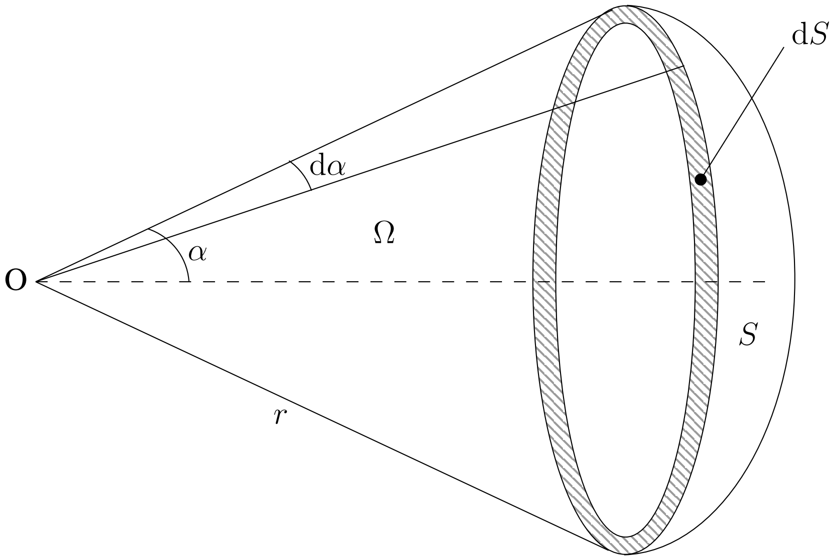

Figure 8.28: **Configuration for the definition of the elementary solid angle of revolution**

It is between two solid angles of revolution whose half-angles at the apex differ of $\mathrm{d}\alpha$:

$$\mathrm{d}\Omega = \mathrm{d}(2\pi(1-\cos(\alpha))) = 2\pi\sin(\alpha)\mathrm{d}\alpha \tag{8.1.189}$$

Therefore:

$$\mathrm{d}\Omega = \frac{\mathrm{d}S}{r^2} \tag{8.1.190}$$

Proof 8.2.2. In the section dealing with Geometric Shapes (see section Geometric Shapes page 2964) we proved the different ways to calculate the area of a sphere. From these calculations it was concluded that the elementary surface with constant radius R was:

$$\mathrm{d}S = r^2\sin(\theta)\mathrm{d}\theta\mathrm{d}\phi \tag{8.1.191}$$

and since:

$$\mathrm{d}\Omega=\frac{\mathrm{d}S}{r^2} \tag{8.1.192}$$

the elementary solid angle is then:

$$\mathrm{d}\Omega=\sin(\theta)\mathrm{d}\theta\mathrm{d}\phi \tag{8.1.193}$$

Thus, the solid angle defined by a cone of revolution, with an apex plane angle equal to α is given by:

$$\begin{gathered}\Omega=\int\mathrm{d}\Omega=\int\limits_0^{2\pi}\mathrm{d}\phi\int\limits_0^{\alpha}\sin(\theta)\mathrm{d}\theta=\phi|_0^{2\pi}\cdot(-\cos(\theta))|_0^{\alpha}\\=2\pi(-\cos(\alpha)-(-\cos(0)))=2\pi(-\cos(\alpha)+1)=2\pi(1-\cos(\alpha))\end{gathered} \tag{8.1.194}$$

8.2. Euclidean Geometry

The purpose of the "Euclidean geometry" (more commonly named "plane geometry") is, in principle, the study of forms and properties of natural bodies. The geometry is however not an experimental science, since its purpose is not to study certain aspects of nature, but a necessarily arbitrary reproduction of it.

We will introduce in this section implicitly, at first, the five postulates of the Euclidean geometry (the first four are nowadays regarded as axioms) and then develop around these basic geometry that will be necessary to the reader need to study the rest of this textbook. Once this is done, we will summarize our study by presenting explicitly the five postulates of Euclid's and then Hilbert's axioms.

Remark

We tried to preserve Euclid's notations as best as possible but although with a little more modern approach to certain concepts and present only those that are useful to Applied Mathematics.

8.2.1 Objects of Euclidean Geometry

Before stating the five Euclid's postulates, it seems good to set some intuitive concepts first (we will introduce the twenty-three Euclid's definition later just before his five postulates!):

Definitions (#8.2.320):

D1. The simplest experimental concept is that of "volume". We say that a body occupies a given volume when it occupies in the three-dimensional space a certain place (for spaces with higher dimensions, we talk about "hyper-volumes").

D2. We assume as obvious that a volume is limited by a "surface"; but if the existence of the volume is physically controllable and measurable, the surface is a creation of the mind; it is something similar to a balloon, for example, wrapping any volume, but only similar. It is a two-dimensional geometric without thickness.

D3. When a surface is limited, this limit is a "line". Again, the line is a creation of the mind, a line has no experimental existence; it is something similar to the figure formed by a wire. Still geometric entity but without width (otherwise it is a surface)... only a length.

D4. A "straight-line" is defined as the unbounded line of shortest distance joining two points on a surface. In other words, A straight line is a line with no beginning and no end, and therefore infinitely long.

D5. When a line is limited (bounded), its limit is a "point": the point is something analogous to the intersection of two stretched wires. This is still a creation of the mind, a geometric being (because it is supposed to have no width, no length, no height... just no dimensions).

Remark

It is customary in geometry to represent a point by a letter $A, B, \ldots$; a line or a surface by a letter in brackets (but this is rarely respected because we often assume the reader knows what we're talking about). Then we write, for example: the line (L), the surface (S).

D6. The term the "segment $\overline{AB}$" generally designates a line bounded by the points A and B. We say that a point M is on the segment $\overline{AB}$ is to translate the following fact: any segment $\overline{AB}$ can be split in an infinity of ways into two pieces limited by A and M on one hand, by M and B on the other - fact actually inspired by the experimental possibility to cut a piece of wire in half, and that in an infinite of ways (we will come back later about this).

Remark

The sentence: «The line (L) is drawn on a surface (S)» means that the surface (S) could be divided into several pieces, so that the line (L) is the boundary or part of a boundary of one of these pieces. This definition is based on the fact that it is possible to cut a tissue, for example by following with scissors any line on this tissue.

When a line (L) is drawn on a surface (S), any point M which is located on the line (L) is, by definition, also located on the surface (S). Then we say that it is a "point of this surface."

D7. A "semi-straight line" is a line which has a boundary (or vertex) on one side and is infinite on the other side.

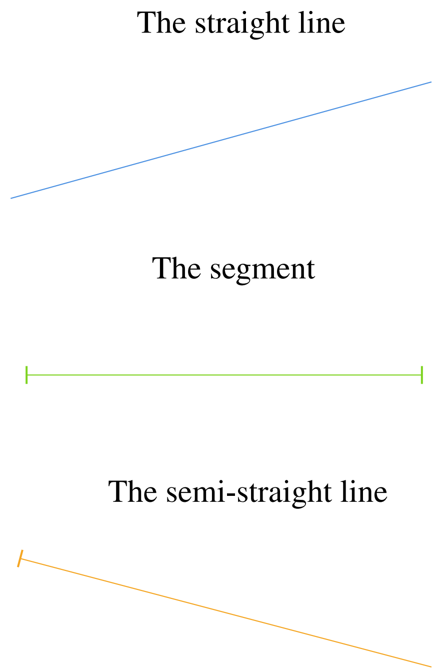

Figure 8.29: **Difference between line, segment and semi-straight line**

D8. We name "angle" (or "plane angle") or more strictly "straight angle" the plane portion limited by two half-lines (see further below the definition of a half-line).

8.2.1.1 Dimensions

We talked before about volume, surface and line to whom we can associate dimensions. But what is a dimension?

We will try to try to define it as best as possible but first, it is important to know that there are several types of dimensions in geometry. The best known and common one is that we name "topological dimension".

For example, the point (mathematical and geometrical abstraction) has a topological dimension of 0, the curve (continuous line of zero thickness) a dimension of 1, a surface a dimension of 2, a volume of a dimensions 3 and a hyper- volume a dimensions of 4 (to represent a hyper-volume take a volume drawn on a paper (...) make it a translation and connect the vertices). These are all integer values by definition:

Dimension: 0
Dimension: 1

(a) A point (b) A line (straight or curved)

Dimension: 2
Dimension: 3

(c) Plane figure/Surface (polygon, ellipse, etc.) (d) A solid or body (sphere, parallelepiped, etc.)

Table 8.3: **Objects, representations and corresponding dimensions**

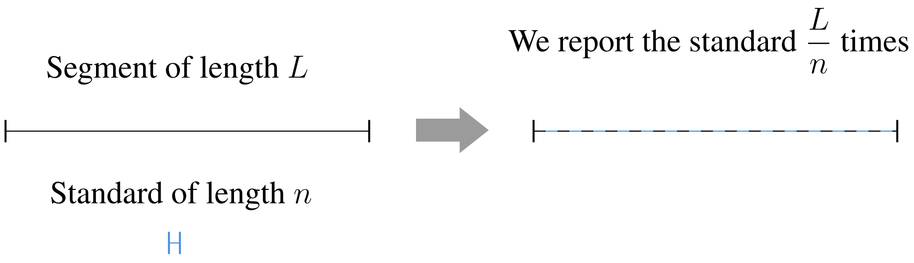
In physics and mathematics, the dimension of a mathematical space (or object) is informally defined as the minimum number of coordinates needed to specify any point within it. Thus a line has a dimension of one because only one coordinate is needed to specify a point on it.

In mathematics, the dimension of an object is an intrinsic property independent of the space in which the object is embedded. For example, a point on the unit circle in the plane can be specified by two Cartesian coordinates, but a single polar coordinate (the angle) would be sufficient (for more details on coordinate systems see the section of Vector Calculus), so the circle is 1-dimensional even though it exists in the 2-dimensional plane. This intrinsic notion of dimension is one of the chief ways the mathematical notion of dimension differs from its common usages.

Dimensions	Example coordinate systems
1	 Number line Angle
2	 Cartesian Polar Latitude and longitude
3	 Cartesian Cylindrical Spherical

Figure 8.30: **Example of some coordinate systems**

To calculate the size of certain objects, we will use the method of the plane metric geometry by taking a standard measure of this object, that is to say the object itself but smaller, and to carry it over our object a given number of times:



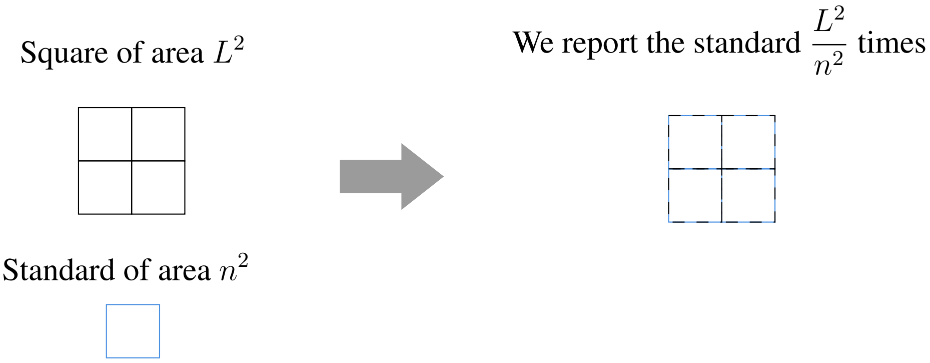
Segment of length L
We report the standard $\dfrac{L}{n}$ times
Standard of length n

Figure 8.31: **Concept of one-dimensional standard**

Let L be the total length of the segment. We will take a standard segment of length n that we will report on the big segment. This standard will be reported L/n times. We will write this:

$$\frac{L}{n}=\left(\frac{L}{n}\right)^{1} \tag{8.2.1}$$

We can apply the same reasoning to a surface:



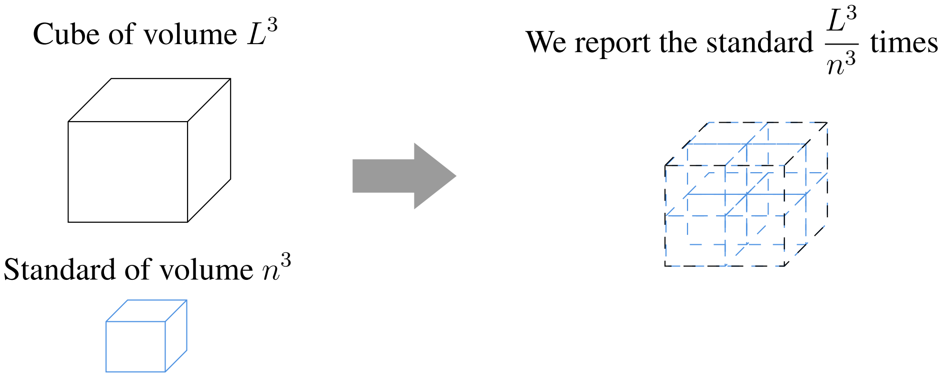
Square of area L^2
We report the standard $\frac{L^2}{n^2}$ times
Standard of area n^2

Figure 8.32: **Concept of two-dimensional standard**

Let L^2 be the total area of the square. We will take a standard square of area n^2 that we will report into the big square. This standard will be reported L^2/n^2 times. We note that:

$$\frac{L^2}{n^2}=\left(\frac{L}{n}\right)^{2} \tag{8.2.2}$$

We can apply the same reasoning to a volume:



Cube of volume L^3
We report the standard $\frac{L^3}{n^3}$ times
Standard of volume n^3

Figure 8.33: **Concept of three-dimensional standard**

Let L^3 be the total volume of the cube. We will take a standard cube of volume n^3 that we will report into the big cube. This standard will be reported L^3/n^3 times. We note that:

$$\frac{L^3}{n^3}=\left(\frac{L}{n}\right)^{3} \tag{8.2.3}$$

and so on...

Through these three examples, we make appear the number 1 for the segment, the number 2 for the square, the number 3 for the volume. These numbers are the "dimension" of the object (same applies for a sphere for example).

So, to summarize:

1. The lines are of dimension 1, because to measure a length with a finer division by a factor n of a standard segment, the number of subdivisions will be multiplied by the same factor. So there is a unity power relation between the subdivision and the measurement.
2. Surfaces are two-dimensional, as for measuring a surface with a finer division by a factor n of a standard square, the number of subdivisions will be given by the square power of n. Therefore there is a power of two relation between the subdivision and the measurement (if we take the square two times smaller to cover a surface, we will need four times the standard).
3. Volumes are 3-dimensional, as for measuring a volume with a finer division by a factor n of a standard cube, the number of subdivisions will be given by the cubic power of n. So there is a power of three relation between the subdivision and the measurement (if we take cubes two time smaller to fill in a volume, we will need eight times the standard).

Let us generalize: let N be the number of times we report the standard of length n on our object of length L, and given d the dimension of the object, we have:

$$\boxed{N=\left(\frac{L}{n}\right)^2 \Leftrightarrow d=\frac{\ln(N)}{\ln(n)}} \tag{8.2.4}$$

In the case of fractals (see section Fractals page 7038) the dimensions are variable and fractional. Consider the Von Koch curve (for example) after one iteration of the sequence defining it:

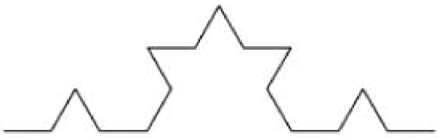


Figure 8.34: **von Koch curve**

Let L be its size such that $L=1$. To calculate its dimension we choose the fundamental element of the curve in red below (yes... we could take the segment of line for sure...):

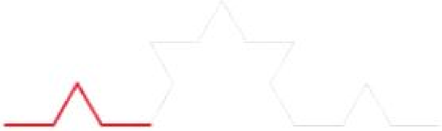

Figure 8.35: **Standard choice for Von Koch curve**

Let n be the size of this standard such as $n=1/3$. We see very well that we can report it 4 times on the curve. Therefore:

$$d=\frac{\ln(4)}{\ln\left(\dfrac{1}{1/3}\right)}=\frac{\ln(4)}{\ln(3)}\cong 1.26 \tag{8.2.5}$$

The dimension of the Von Koch fractal therefore has a fractional value and is more a curve (because close to 1), rather than a surface (which is of dimension 2). Cauliflowers are for example fractals with dimension 2.33...

So we can calculate the size of any fractal objects on condition of knowing their standard measurement.

We don't venture fetching complex objects in some galaxies, while the most famous fractal is in your plate (the second being your lungs ...). Eh yes! Cauliflower is a fractal (as well as your lungs)! You've probably noticed that when we cut cauliflower (not something recommended to try with your lungs ...), we are breaking it instead of cutting it, and it gives lots of small cauliflower, which themselves may give other smaller cauliflower. This characteristic of self-similarity at different scales is makes the cauliflower a fractal.

Let us calculate now the fractal dimension of cauliflower. When we break cauliflower, we get between 12 and 14 branches that resemble to the whole cauliflower close to a given scale... This expansion is, if we calculate it, of a factor 3. So according to the formula above, the fractal dimension of the cauliflower is approximately:

$$d=\frac{\ln(13)}{\ln(3)}\cong 2.33 \tag{8.2.6}$$

So the cauliflower is closer of a surface than a volume.

Let us do one last example with Sierpinski triangle fractal (see section Fractals page 7062):

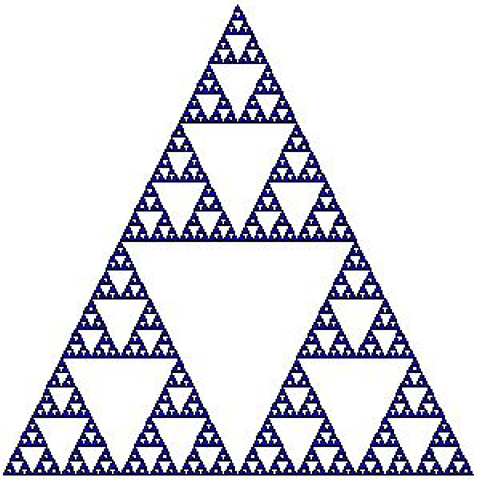

Figure 8.36: Sierpinski triangle fractal

First, it is clear that we need a square to cover it (round it) completely. With squares two times smaller, we will need three squares:

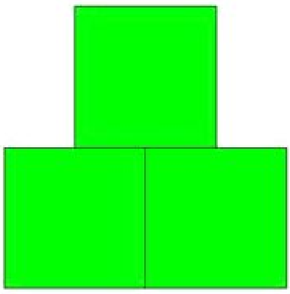

Figure 8.37: Three squares to cover the Sierpinski fractal

If we divide again once the size of the squares by two, we will need 9 squares to cover the triangle:

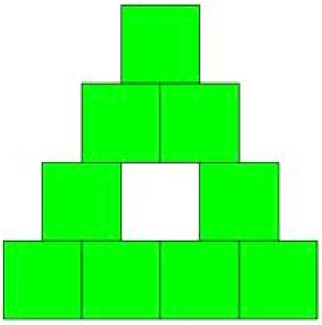

Figure 8.38: Nine squares to cover the Sierpinski fractal

If we divide once again the size of the square by two we will need 27 of them:

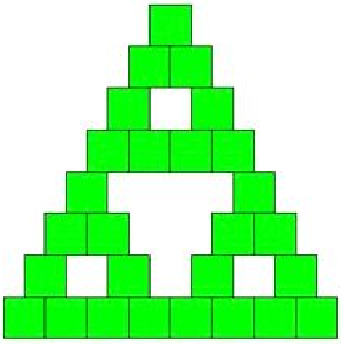

Figure 8.39: Twenty seven squares to cover the Sierpinski fractal

And there we see that:

$$3=2^{\frac{\ln(3)}{\ln(2)}},9=4^{\frac{\ln(3)}{\ln(2)}},27=8^{\frac{\ln(3)}{\ln(2)}} \tag{8.2.7}$$

And therefore:

$$\frac{\ln(3)}{\ln(2)}\cong 1.585 \tag{8.2.8}$$

So the Sierpinski fractal is closer to a surface than a curve.

There exist also other dimensions. Take for example the "homothetic dimensions" Here are some simple examples (see further below the strict definition of "homothetic transformation"):

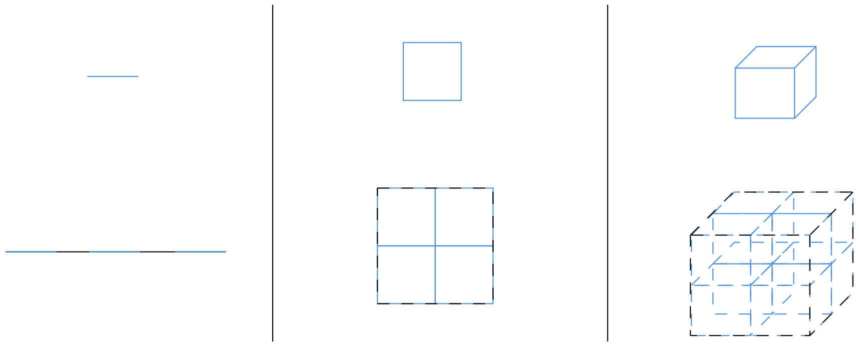

Figure 8.40: **Representation of homothetic dimensions**

The segment (far left), of 1-dimension, has by homothetic transformation seen its length doubled, we note that:

$$d=1, H=2, N=2^1=2 \tag{8.2.9}$$

The square (at the center), of 2-dimension has by homothetic transformation seen its surface doubled and we note that:

$$d=2, H=2, N=2^2=4 \tag{8.2.10}$$

The cube (far right), of 3-dimension has by homothetic transformation seen its volume has quadruple and we note that:

$$d=3, H=2, N=2^3=8 \tag{8.2.11}$$

The duplication of scale factor (homothetic) is therefore equal to:

$$2^{\text{Topological dimension}} \tag{8.2.12}$$

As you can see, this is always an integer value but of a different kind of dimension.

The concept of dimensions having been introduced let us look now to the Euclid's postulates which may seem vague at first but will be detailed as we go far in our reading of this section.

8.2.2 Euclid's Constructions

The construction of the planar Euclidean geometry is based on twenty-three definitions and five postulates (the first four are today regarded as axioms as we have already mentioned it).

Let us start with the traditional definitions:

Definitions (#8.2.321):

D1. A "point" is that which has no part.

D2. A line is a breadthless "length".

D3. The "ends" of a line are points.

D4. A "straight line" is a line which lies evenly with the points on itself.

D5. A "surface" is that which has length and breadth only.

D6. The "edges" of a surface are lines.

D7. A "plane surface" is a surface which lies evenly with the straight lines on itself.

D8. A "plane angle" is the inclination to one another of two lines in a plane which meet one another and do not lie in a straight line.

D9. And when the lines containing the angle are straight, the angle is named a "rectilinear angle".

D10. When a straight line standing on a straight line makes the adjacent angles equal to one another, each of the equal angles is a "right angle", and the straight line standing on the other is named a "perpendicular line" to that on which it stands.

Remark

As we will see in the section of Analytical Geometry (see page 2811), perpendicularity doesn't only exists with straight lines on a plane but also with curves like the famous case of a circle and a straight line passing through its origin!

D11. An "obtuse" angle is an angle greater than a right angle.

D12. An "acute" angle is an angle less than a right angle.

D13. A "boundary" is that which is an extremity of anything.

D14. A "figure" is that which is contained by any boundary or boundaries.

D15. A "circle" is a plane figure contained by one line such that all the straight lines falling upon it from one point among those lying within the figure equal one another.

D16. And the point is named the "center" of the circle.

D17. A "diameter" of the circle is any straight line drawn through the center and terminated in both directions by the circumference of the circle, and such a straight line also bisects the circle.

D18. A "semicircle" is the figure contained by the diameter and the circumference cut off by it. And the center of the semicircle is the same as that of the circle.

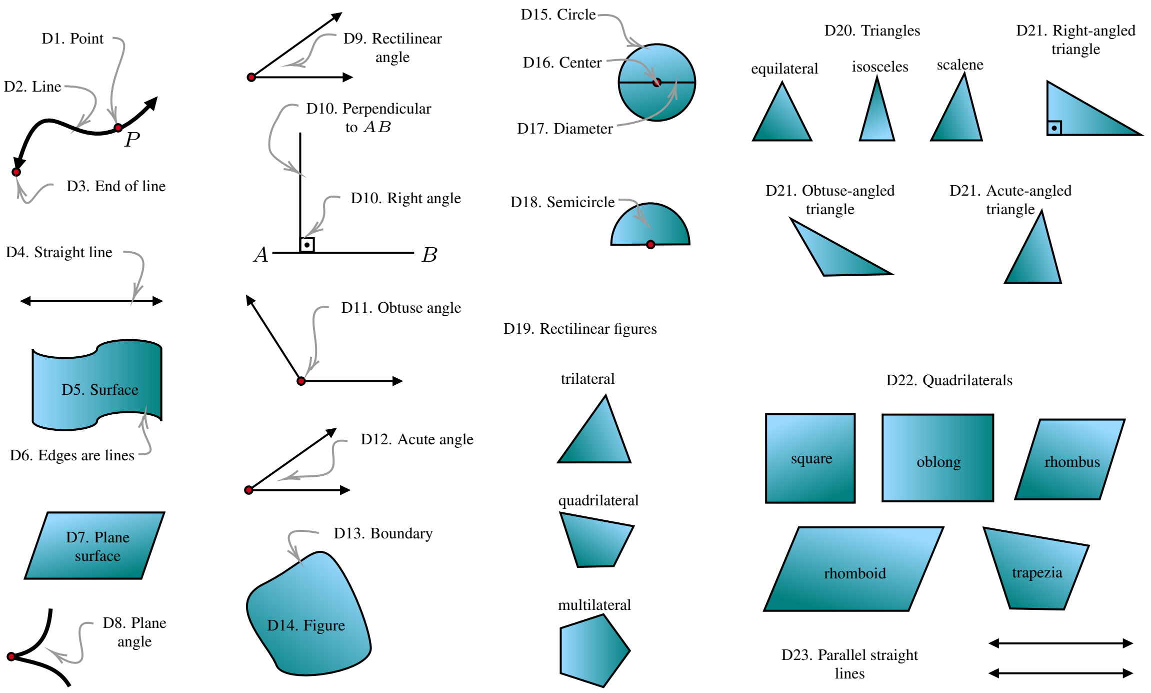
D19. "Rectilinear figures" are those which are contained by straight lines, trilateral figures being those contained by three, quadrilateral those contained by four, and multilateral those contained by more than four straight lines.

D20. Of "trilateral figures", an equilateral triangle is that which has its three sides equal, an isosceles triangle that which has two of its sides alone equal, and a scalene triangle that which has its three sides unequal.

D21. Further, of trilateral figures, a "right-angled triangle" is that which has a right angle, an "obtuse-angled triangle" that which has an obtuse angle, and an "acute-angled triangle" that which has its three angles acute.

D22. Of quadrilateral figures, a "square" is that which is both equilateral and right-angled; an "oblong" that which is right-angled but not equilateral; a "rhombus" that which is equilateral but not right-angled; and a "rhomboid" that which has its opposite sides and angles equal to one another but is neither equilateral nor right-angled. And let quadrilaterals other than these be named "trapezia".

D23. "Parallel straight lines" are straight lines which, being in the same plane and being produced indefinitely in both directions, do not meet one another in either direction.



D1. Point
D2. Line
P
D3. End of line
D4. Straight line
D5. Surface
D6. Edges are lines
D7. Plane surface
D8. Plane angle
D9. Rectilinear angle
D10. Perpendicular to AB
D10. Right angle
A
B
D11. Obtuse angle
D12. Acute angle
D13. Boundary
D14. Figure
D15. Circle
D16. Center
D17. Diameter
D18. Semicircle
D19. Rectilinear figures
trilateral
quadrilateral
multilateral
D20. Triangles
equilateral
isosceles
scalene
D21. Right-angled triangle
D21. Obtuse-angled triangle
D21. Acute-angled triangle
D22. Quadrilaterals
square
oblong
rhombus
rhomboid
trapezia
D23. Parallel straight lines

Figure 8.41: **The 23 definitions of Euclid illustrated**

And now let us introduce Euclid's five postulates:

P1. Drawing a straight line of any point to any point.

In a modern way we would say that through two distinct points A and B, it passes a straight line and it goes in only one.

In other words, two straight lines (D) and (D') which have two common points are coincident, any point of one is a point of the other and vice versa.

It follows from this postulate that two lines (D) and (D') have no common point or have a single common point named "intersection" and are then "intersecting" and "distinct" or have more than one common point and are then "combined".

P2. Extend indefinitely, in its direction, a finite straight line.

In a modern way we will say that any finite segment $\overline{AB}$ can be extended in a straight line passing through A and B (given the first axiom, it is unique in Euclidean geometry).

P3. From any point and with any interval, describe a circle circumference.

In a modern way we will say that for any point A and any separate point B of A, we can draw a circle with center A passing through B.

P4. All right angles are equal.

Under modern form we say that for every angle $\widehat{xyz}$ of the plane corresponds its measurement θ (also denoted in high-school by $\measuredangle AOB$), performed with a unit chosen once for all where θ is a positive number, less than 2π. Conversely, let θ be any positive number between 0 and 2π, we shall assume that there is an infinite number of angles $\widehat{xyz}$ equal to one another whose measurement with the chosen angle unit is θ.

P5. If a straight line, falling on two straight lines, makes the interior angles on the same side smaller than two right angles, these lines, extended to infinity, will meet at the side where the angles are smaller than the two rights.

In a modern way we will say that given a straight line and a point, there is a unique line through this point and not intersecting the initial right.

Notice that these postulates were constructed in an old way as independent constructions. In modern mathematics we always try to define axioms (or postulates) based on relationships between concepts and not as independent constructions.

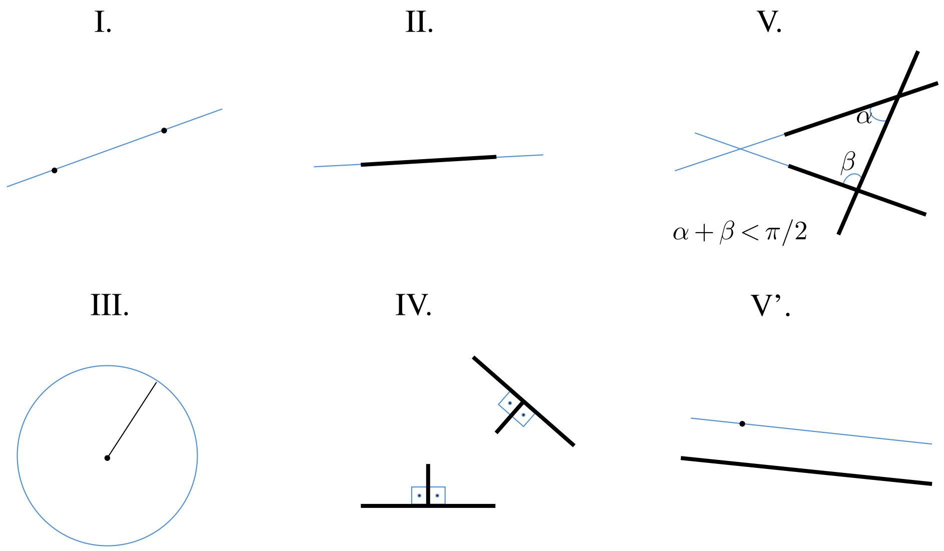


Figure 8.42: **Illustrated summary of five Euclid's postulates**

The Euclid's postulates will allow us the development of the concept of measurement of a length, area, volume, angle, as we shall see below.

Euclid's fifth postulate cannot be proven as a theorem from the four first postulates, although this was attempted by many people. Euclid himself used only the first four postulates ("absolute geometry") for the first 28 propositions of the *Elements*, but was forced to invoke the parallel postulate on the 29th. In 11823 (holocene calendar), Janos Bolyai and Nicolai Lobachevsky independently realized that entirely self-consistent "non-Euclidean geometries" could be created in which the parallel postulate did not hold (Gauss had also discovered but suppressed the existence of non-Euclidean geometries).

The two most fundamental theorems of Euclidean geometry are the Pythagorean theorem and the Thales theorem that we will prove later! A bit of analysis permits us to go further with Trigonometry that we have already developed in the previous section.

8.2.2.1 Segments and Lines

First, the simplest geometric figure (excepted the point ...) in Euclidean geometry is the "straight line" and it is directly concerned by the first two Euclid's postulates.

Definitions (#8.2.322):

D1. The "straight line" is the image given by a tensioned wire of zero thickness and infinite length.

> **Remark**
>
> We can also define the "straight line" as an infinity of points placed next to each other in a same direction on a plane.

D2. We name "half-line" the portion of a line limited to a point O named "origin".

Remark

The expression the "half-line $\overline{\mathrm{O}A}$" means the half-line of origin O, point named the "first", which contains the point A.

D3. We say that two half-lines $\overline{\mathrm{O}A}$, $\overline{\mathrm{O}B}$ are "opposing half-lines" when they constitute the whole line $\overline{AB}$.

D4. We name "segment $\overline{AB}$" the portion of a right straight line limited by two points A and B. These points are named the "extremities" of the segment.

8.2.2.1.1 Quantities of the same type

We say that geometric figures (meaning straight lines) are of the "same type quantities" when it is possible to define:

1. In which case a figure (A) is said to be equal to a figure (B) and, if they are unequal, which is the smallest.
2. What we need to understand when we sum a figure (A) and a figure (B).

The definitions should be chosen such that if (A) is smaller than said (B) and (B) smaller than (C), then (A) must be reported to be small than (C).

It is necessary, moreover, that the figure resulting of the sum of (A) and (B) is equal to that which is named: sum of (B) and (A).

Finally, a substitution in a comparison, or an equal amount, of a figure by an identical figure should not affect the result of operations.

To understand what are the quantities of the same type, take the example of line segments:

- We admit that it is possible to determine the equality of two segments $\overline{AB}$ and $\overline{A'B'}$ when we can make them coincide.
- We also admit that it is possible to replace the segment $\overline{A'B'} \in AB$ by an equal segment $\overline{AD}$ and putt on the line AB.
- Finally, we will assume that it is possible to distinguish between three points A, B, C, taken at random on a line or segment and to know which is between the other two.

We then agree to say that the segment $\overline{A'B'}$ is smaller than the segment $\overline{AB}$, which is written formally (see section Operators page 288):

$$\overline{A'B'} < \overline{AB} \tag{8.2.13}$$

when the point C, obtained by putting it on the segment $\overline{AB}$ a segment $\overline{AC}$ equal to $\overline{A'B'}$, falls between A and B.

If the point C was on B, the segments $\overline{AB}$ and $\overline{A'B'}$ would be equal and then we would write:

$$\overline{A'B'} = \overline{AB} \tag{8.2.14}$$

We agree to named "sum of two segments" $\overline{AB}$, $\overline{A'B'}$, the segment $\overline{AC}$ obtained by translating on the half-line opposed to the segment $\overline{BA}$ a segment $\overline{BC}$ equal to $\overline{A'B'}$. We translate this by writing:

$$\overline{AC} = \overline{AB} + \overline{A'B'} \tag{8.2.15}$$

Let us still consider quantities of the same species ... Add therebetween several of these quantities is to add one of them to another, the sum determined to another third, etc. For example, add the segments $\overline{AB},\overline{BC},\overline{CD}$, is add $\overline{AB}$ and $\overline{BC}$ which gives $\overline{AC}$, then $\overline{AC}$ and $\overline{CD}$ which gives $\overline{AD}$. We summarize the operation by writing:

$$\overline{AD}=\overline{AB}+\overline{BC}+\overline{CD} \tag{8.2.16}$$

Multiply by a quantity by an integer n, it is n quantities to itself. For example, if we have $\overline{AB}=\overline{BC}=\overline{CD}$, the above relation would be written:

$$\overline{AD}=3\overline{AB}=3\overline{BC}=3\overline{CD} \tag{8.2.17}$$

We will now define what we name "compare two quantities (A) and (B) of the same kind". For this let us arbitrarily select a quantity (C) of the same kind as (A) and (B) and smaller than each of them. Let us build a sequence of quantities such that:

$$(C_1)=(C),(C_2)=2(C),\ldots,(C_p)=p(C),\ldots,(C_n)=n(C) \tag{8.2.18}$$

We find that the quantity (A) is between two quantities (C_p) and (C_{p+1}) and that (B) is located between two others (C_q) and $(C_{q+1}$ by construction.

We then say by definition that the ratio of the quantities (A) and (B) is a positive number $(A)/(B)$ between:

$$\left[\frac{(C_p)}{(C_{q+1})},\frac{(C_{p+1})}{(C_q)}\right] \tag{8.2.19}$$

✍**Example:**

Consider then, for example, any two segments $\overline{AB},\overline{A'B'}$ but different (e.g. $1.2\,[\text{cm}]$ and $3.5\,[\text{cm}]$):

To perform the previous operation, let us use a graduated rule which unit will be the quantity (C), an arbitrary segment (for example $1\,[\text{cm}]$).

We apply the zero of the rule on A, and B will by design intercalate between two graduations of the rule numbered p and $p+1$ unless the size (C) is equal to $\overline{AB}$ ... (either with the choice taken as an example, B intercalate between the 1st and 2nd graduation).

For $\overline{A'B'}$, we apply the zero of the rule also on A', and B' also intercalate between two values of the rule numbered q and $q+1$ unless the variable C is equal to $\overline{A'B'}$ ... (either with the choice taken as an example, B' will intercalate between the 3rd and the 4th one).

We will express the results of these measurements and their ratio by writing:

$$\frac{p}{q+1}<\frac{\overline{AB}}{\overline{A'B'}}<\frac{p+1}{q} \tag{8.2.20}$$

where the term on the left extremity is named a "default measurement" and this at the opposite a "measurement by excesses".

So with the measures taken as an example we have:

$$\frac{1}{3+1}<\frac{\overline{1.2}}{\overline{3.5}}<\frac{1+1}{3}\Leftrightarrow 0.25<0.342<0.\bar{6} \tag{8.2.21}$$

Definition (#8.2.323): And in physics, we name "measure of a quantity" (A) the positive number which measures the ratio of this size and a quantity (U) arbitrarily chosen as reference and which we name the "unit", the measuring unit being "1", by definition.

We can show that if a is a measure of (A), b that of (B) evaluated both with the same unit (U), the number $(A)/(B)$ is equal to the ratio a/b. This ratio is (and this should be obvious for the reader at this level) independent of the chosen unit of measurement.

Remark

We say that (B) is an "aliquot part" of (A) if the ratio $(A)/(B)$ is an integer.

We will agree once and for all, that in geometry all quantities of the same species that occur in a given figure are measured with the same unit.

Given $(A),(B),(C),\ldots,(S)$ quantities of the same species and $(A'),(B'),(C'),\ldots,(S')$, quantities of the same species, but that are not necessarily of the same kind as the previous. We say that these quantities are "homologous" if we can group them in pairs, (A') homologous to (A), (B') homologous to (B), ..., etc., so that following conditions are met:

- If (A) is equal to (B), (A') is equal to (B').
- If (A) is smaller than (B), (A') is smaller than (B').
- If (S) is the sum of (A) and (B), (S') is the sum of (A') and (B').

To calculate the ratio $(A)/(B)$, let us build the following sequence $(C_1),(C_2),\ldots,(C_p)$ and to calculate the ratio $(A')/(B')$, let us build the sequence $(C'_1),(C'_2),\ldots,(C'_p)$ following equation, obtained as the previous one, but from the quantity (C') homolog of (C).

It is obvious that if (A) can be intercalate between (C_p) and (C_{p+1}), (A') could therefore also be intercalate between (C'_p) and (C'_{p+1}); Similarly, if (B) can be intercalated between (C_q) and (C_{q+1}). The ratios $(A)/(B)$ and $(A')/(B')$ will be bounded by the same numbers:

$$\frac{p}{q+1} \qquad \frac{p+1}{q} \tag{8.2.22}$$

Consequently, the ratio between two quantities (A) and (B) is equal to the ratio of the homolog quantities (A') and (B').

If, in particular, the quantities $(A),(B),\ldots$ are measured with a unity (U), and if the quantities $(A'),(B'),\ldots$ are measured with the sames unities (U'), homolog of (U), the equal ratios:

$$\frac{(A)}{(U)} \qquad \frac{(A')}{(U')} \tag{8.2.23}$$

are only the measurement of (A) and of (A'). Consequently:

The measurements of two homolog quantities (A) and (A') are equal at the condition that the chosen units to measure them are also homolog quantities.

Les us consider now on a half-line along Ox-axis a point M. Given x the measurement (following previous definition) of $\overline{\text{O}M}$. For every point M of the half-line $\overline{\text{O}M}$ corresponds a unique positive x. We will admit that to any positive value x randomly chosen correspond a unique point M on the half-line.

A consequence of this assumption is that there is a point, and only one, C, which divides the segment $\overline{\text{O}M}$ in equal parts. This point is the point of the half-line $\overline{\text{O}M}$, such that:

$$\overline{\text{O}C} = \frac{\overline{\text{O}M}}{2} \tag{8.2.24}$$

We name this point the "middle of the segment" $\overline{\text{O}M}$.

Theorem 8.3. There exists a point M and only one located on the segment $\overline{AB}$ such that the relation $\overline{MA}/\overline{MB}$ is equal to a given positive number.

Remark

Obviously if $\lambda = 1$, this point is the middle of the segment.

Proof 8.3.1. Given M any point of the segment $\overline{AB}$ on a plane; given x, the measurement of $\overline{AM}$ and a the measurement of $\overline{AB}$: the measurement of $\overline{MB}$ will be equal to $a-x$ since M is placed between A and B. We will have:

$$\frac{\overline{MA}}{\overline{MB}} = \frac{x}{a-x} \tag{8.2.25}$$

For this ratio to be equal to λ, we have to, and it is sufficient to, that x is solution of the equation:

$$\frac{x}{a-x} = \lambda \tag{8.2.26}$$

This equation has for unique solution:

$$x = \frac{a\lambda}{1+\lambda} \tag{8.2.27}$$

To this positive x value that is less than a corresponds a point M and only one of the half-line $\overline{AB}$ such as $\overline{MA} = x$. This point M satisfies, and satisfied alone, to the imposed conditions.

■ Q.E.D.

Theorem 8.4. There is a point M and only one of the line $\overline{AB}$, located outside the segment $\overline{AB}$, such as the ratio $\overline{MA}/\overline{MB}$ equals a given definite number λ and from 1.

Proof 8.4.1. Let us prove this uniqueness in two steps:

1. Let us suppose $\lambda > 1$. Given M any point of the line $\overline{AB}$ located outside the segment $\overline{AB}$: even A is on the $\overline{MB}$ segment, or B is on the $\overline{MA}$ segment. If A is the $\overline{MB}$ segment, we have necessarily $\overline{MB} > \overline{MA}$, thus:

   $$\frac{\overline{MA}}{\overline{MB}} < 1 < \lambda \tag{8.2.28}$$

   The point M thus does not respond to the question of uniqueness.

   If B is on the segment $\overline{MA}$ and we denote $\overline{MA} = x$, $\overline{AB} = a$, $\overline{MB} = x - a$. So we have:

   $$\frac{\overline{MA}}{\overline{MB}} = \frac{x}{x-a} \tag{8.2.29}$$

   For this ratio to be equal to λ, it is necessary, and sufficient that x is a solution of the equation:

   $$\frac{x}{x-a} = \lambda \tag{8.2.30}$$

   This equation admits as unique solution:

   $$x = \frac{a\lambda}{\lambda - 1} \tag{8.2.31}$$

   that gives a value of x that will always be positive and greater than λ. To this positive x value and greater than a corresponds a point M and only one of the half-line $\overline{AB}$. This point M satisfies, and only it, to the conditions of uniqueness imposed.

2. Let us suppose that $\lambda < 1$. We will seek the point M for which (we simply reversed the ratio):

   $$\frac{\overline{MB}}{\overline{MA}} = \frac{1}{\lambda} \tag{8.2.32}$$

   is a number greater than 1. There is one and only one from the point (1). It is the only one that satisfies the imposed conditions.

Remark

There is no point M located outside the segment $\overline{AB}$ for which $\overline{MA}/\overline{MB} = 1$. Indeed, if A is on the $\overline{MB}$ segment, we have regardless of M, $\overline{MA}/\overline{MB} < 1$, and if B is on the segment $\overline{MA}$, $\overline{MA}/\overline{MB} > 1$....

■ Q.E.D.

8.2.3 Plane Geometry

Let us now study a geometrical object of greater dimension than that of the straight line that is the Plane and the Surface.

A plane is a flat, two-dimensional surface that extends infinitely far. A plane is the two-dimensional analogue of a point (zero dimensions), a line (one dimension) and three-dimensional space. Planes can arise as subspaces of some higher-dimensional space, as with a room's walls extended infinitely far, or they may enjoy an independent existence in their own right, as in the setting of Euclidean geometry.

When working exclusively in two-dimensional Euclidean space, the definite article is used, so, "the plane" refers to the whole space. Many fundamental tasks in mathematics, geometry, trigonometry, graph theory and graphing are performed in a two-dimensional space, or in other words, in: "the plane".

Let us now consider a finite surface (S) and two points A and B of this surface. At least two simple cases are possible:

1. There are points of the straight segment $\overline{AB}$ that are not on the surface (S). We say in this case that: "the segment $\overline{AB}$ intersects the surface"; the common point to the segment $\overline{AB}$ and the surface (S) are the intersection points of the surface (S) and of the segment $\overline{AB}$. Among these common points there are especially the points A and B.

2. All points on the segment $\overline{AB}$ are points of the surface (S). We say then that: "the segment $\overline{AB}$ is on the surface (S)".

Definition (#8.2.324): We name "plane" the surface such that any segment $\overline{AB}$ joining two points arbitrarily chosen on the surface, is on the surface.

We will assume that such a surface exists and that in an Euclidean space of any number of dimensions, a plane is uniquely determined by any of the following:

- Three non-collinear points (points not on a single line).
- A line and a point not on that line.
- Two distinct but intersecting lines.
- Two parallel lines.

The following properties hold in three-dimensional Euclidean space but not in higher dimensions, though they have higher-dimensional analogues:

P1. Two distinct planes are either parallel or they intersect in a line.

P2. A line is either parallel to a plane, intersects it at a single point, or is contained in the plane.

P3. Two distinct lines perpendicular to the same plane must be parallel to each other.

P4. Two distinct planes perpendicular to the same line must be parallel to each other.

The study of planes will be made later in this section (but the mathematical vectorial analysis of a plane is done the in the section of Analytical Geometry). We will first focus on the study of geometric figures drawn in a given plane, figures named "plane figures". Their study is related to the field of "plane geometry".

All the shapes exist in a flat plane. A plane can be thought of an a flat sheet with no thickness, and which goes on for ever in both directions. It is absolutely flat and infinitely large, which makes it hard to draw.

Remarks

R1. The study of geometry can be broken into two broad types: plane geometry, which deals with only two dimensions, and solid geometry which allows all three. The world around us is obviously three-dimensional, having width, depth and height, Solid geometry deals with objects in that space such as cubes and spheres.

R2. In practice, the figures are drawn either on a sheet of paper or on the surface of the blackboard (or on a computer screen).

8.2.3.1 Displacements and Turnarounds

Given (F) a drawing made on a plane board. Imagine we do on a transparent layer, which front is applied on the board, a copy (C) of the drawing (F). Let us perform afterwards, by moving this transparent layer on another point of the plane board, a new drawing a new drawing (F') identical to (F).

Two major cases have to be considered mathematically speaking:

1. If the recto side of the transparent layer is remained applied to the plane board, the drawing (F') is obtained from (F) by an operation named "displacement" or more commonly "translation".
2. If, however, the transparent layer was horizontally or vertically returned, and if it is the verso that is applied to the plane board, the operation is named "turnaround" or more commonly a "vertical or horizontal symmetry".

At each point A of the drawing (F), any one of these two operations corresponds to a point A' of the drawing (F'), which we name "the homologue" of A. A segment $\overline{AB}$ of (F) coincides with a homologous segment $\overline{A'B'}$ of (F'); these two segments are by definition equal regardless of A and B.

In the figure below the red triangle is a translation of the blue one. The green triangle is a horizontal symmetry of the blue one plus a translation:

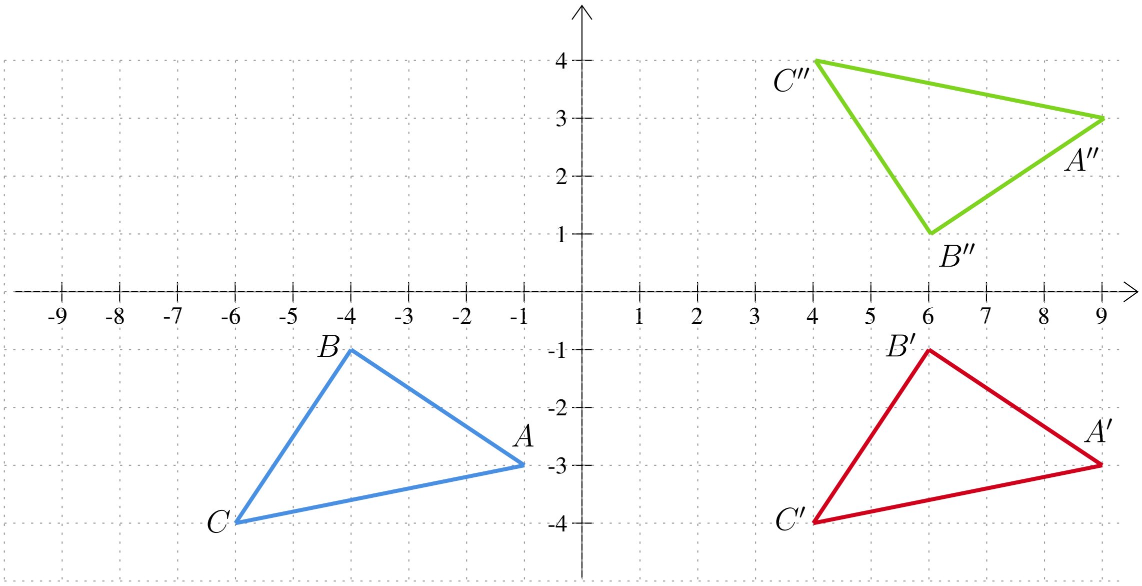

Figure 8.43: **Illustrated example of a translation and a symmetry**

Definition (#8.2.325): We commonly say that the drawing (F) is "stackable" to drawing (F') and that these drawings represent equal figures.

8.2.3.2 Plane angles

We have already defined the concept of "angle" in the previous section on Trigonometry (circle angle and spherical angle). We now have more the fourth Euclid's postulate at our disposal regarding the concept of plane angle.

We will now come back more in detail about the concepts of plane angle and see the underlying concepts that will enable us to address further a particularly useful object which is the bisecting line!

Definitions (#8.2.326):

D1. We name "angle" (or "plane angle") or more strictly "linear angle" the plane portion bounded by two half-lines OA, OB, for example. The point O is named the "top" of the angle, the half-lines OA, OB are named the "sides" of the angle.

In highs-school, angles are measured with an instrument named a "protractor":

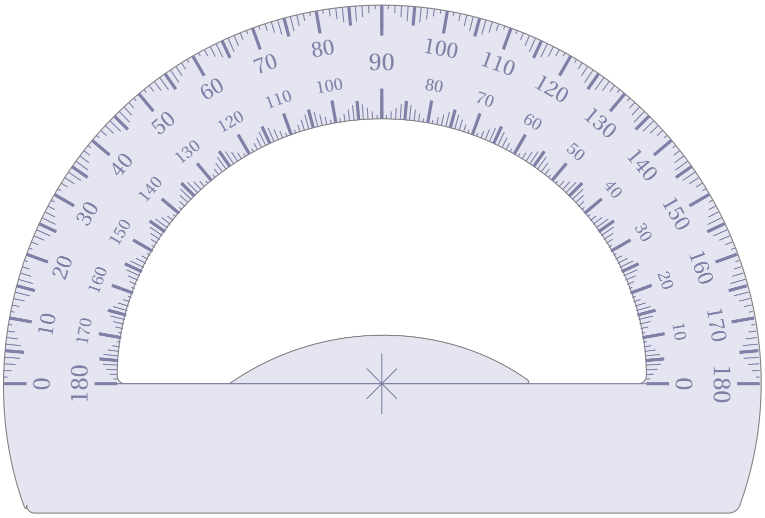

Figure 8.44: **A half circle protractor marked in degrees** (180°)

D2. We name "angle between two half-lines AB, AC", the angle of top A which sides are the half-lines AB, AC.

D3. The half-lines OA, OB divide the plane into two regions: they therefore define two angles:

(a) One consists of the covered hatch area (see figure on the far left below) is named "salient angle".

(b) The other consists of the covered hatch covered (see figure on the center below) is named "reflex angle".

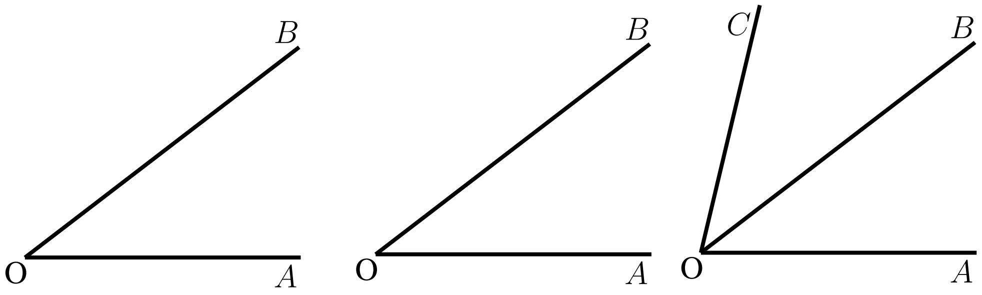

Figure 8.45: **Salient angle, reflex angle, adjacent angle**

The notation $\widehat{BOA}$ or $\widehat{AOB}$ denotes one of the two angles: the letter that designate the top should be (usually) written in the middle (often we do not mention the top if the context is clear). Where no precision accompanies this notation, it is by definition the salient angle!!

D4. We name "adjacent angles" two angles which have the top and one side that are common and which are placed on either side of the common side. In the figure above the far right, the saillant angles $\widehat{AOB}$, $\widehat{BOC}$ are adjacent.

Given $\widehat{AOB}$ and $\widehat{A'OB'}$ two angles of a sample plane. We have assumed previously that there is a displacement that brings O$'$ on O and A' on a point A of the line OA. This movement causes $\text{O}'B'$ to move either on $\text{O}B_1$ so that the two angles $(\widehat{A\text{O}B},\widehat{A\text{O}B_1})$ are not adjacent, or on $\text{O}B_2$ so that $(\widehat{A\text{O}B},\widehat{A\text{O}B_2})$ are adjacent.

In the latter case, an additional half turn around $\text{O}A$ will bring $\widehat{A\text{O}B_2}$ into the position $\widehat{A\text{O}B_1}$. This movement and this rotation, if it occurs, replace $\widehat{A'\text{O}'B'}$ by an angle $\widehat{A\text{O}B_1}$ that is equal by definition.

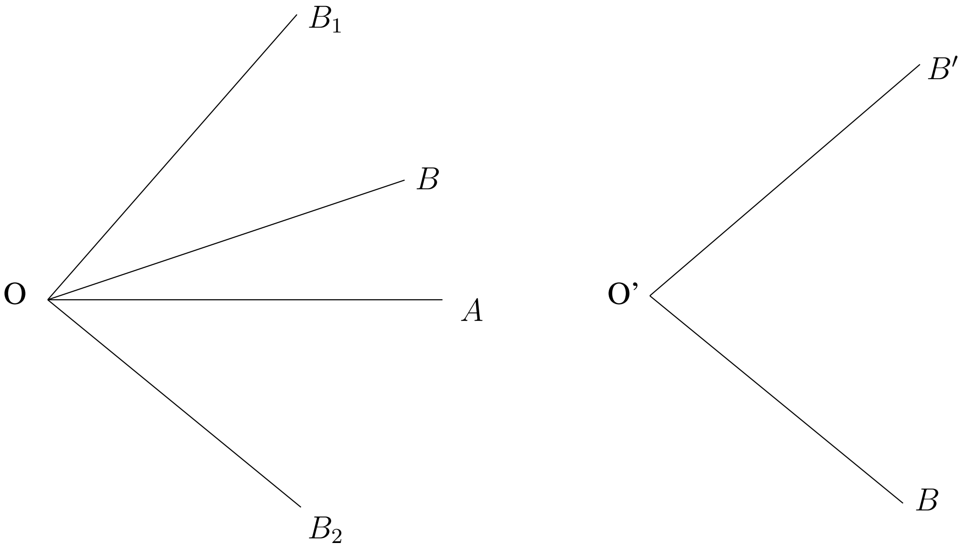

Figure 8.46: **Representation of the movement of two angles**

If $\text{O}B_1$ is merged with $\text{O}B$, there are points of one of the two angles $\widehat{A\text{O}B_1}$ and $\widehat{A\text{O}B}$ that are equal, any point of one being a point of the other, we say, in this case that: the angles $\widehat{A\text{O}B}$, $\widehat{A'\text{O}'B'}$ are "equal angles", which is expressed by the expression:

$$\widehat{A\text{O}B}=\widehat{A'\text{O}'B'} \tag{8.2.33}$$

If $\text{O}B_1$ is not merged with $\text{O}B$, there are points of one of the two angles $\widehat{A\text{O}B_1}$, for example, which are not points of $A\text{O}B$. On the figure above, the angle $\widehat{A\text{O}B}$ is covered by hatch, the angle $\widehat{A\text{O}B_1}$ also. The points we are speaking about are those of the angle $\widehat{B\text{O}B_1}$ covered only once by hatch. We will agree to say that the angle $\widehat{A\text{O}B_1}$ and, therefore, the angle equal to $\widehat{A'\text{O}'B'}$ are, in this case, greater than the angle $\widehat{A\text{O}B}$, which is expressed by the inequality:

$$\widehat{A'\text{O}'B'}>\widehat{A\text{O}B} \tag{8.2.34}$$

Now that we are able to compare angles, let us study how we can sum the up (and thus subtract respectively).

Let us study first the case of the sum of two adjacent angles $\widehat{A\text{O}B}$, $\widehat{B\text{O}C}$. Two cases can occur following that the angles are salient angles or reflex angles:

(a) Given $\widehat{A\text{O}B}$ and $\widehat{B\text{O}C}$ the two angles to sum (see left figure below). By definition, the sum of these angles is the angle $\widehat{A\text{O}C}$, what we express by the equality:

$$\widehat{A\text{O}C}=\widehat{A\text{O}B}+\widehat{B\text{O}C} \tag{8.2.35}$$

(b) Given $\widehat{AOB}$ a salient angle to sum up to the reflex angle $\widehat{BOC}$. If we cover of hatch successively the both angles (see right figure below), the salient angle $\widehat{AOC}$ is covered twice:

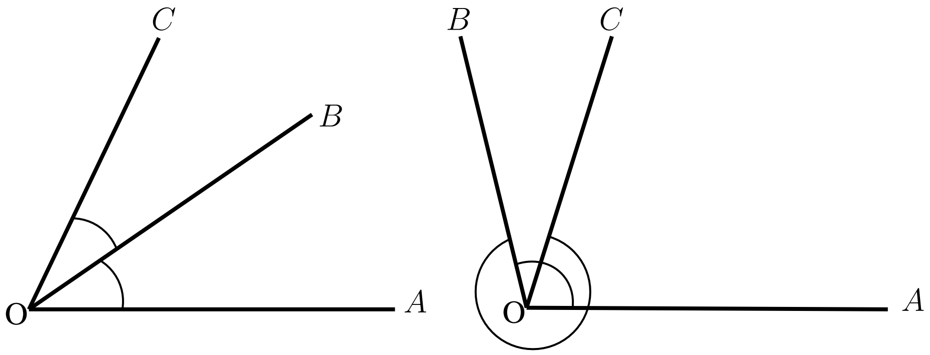

Figure 8.47: **Sum of two adjacent angles**

In this case, the sum of the angles $\widehat{AOB}$ (saillant) and $\widehat{BOC}$ (reflex) is therefore equal to $\widehat{AOC}$ plus two "flat angles" (see below for the definition), which is expressed by writing:

$$\widehat{AOB}+\widehat{BOC}=\widehat{AOC}+2\,\text{flat angles} \tag{8.2.36}$$

Remark

This may seem confusing to some but those who have already read the section of Trigonometry know already that the angles of the trigonometric circle are equal to themselves modulo 2π [rad].

Let us now study the case of the sum of any two angles:

The sum of two angles $\widehat{AOB}$, $\widehat{A'O'B'}$ is, by definition, equal to the sum of the angle $\widehat{AOB}$ and of an angle $\widehat{BOC}$ equal to the angle $\widehat{A'O'B'}$ and adjacent to the angle $\widehat{AOB}$.

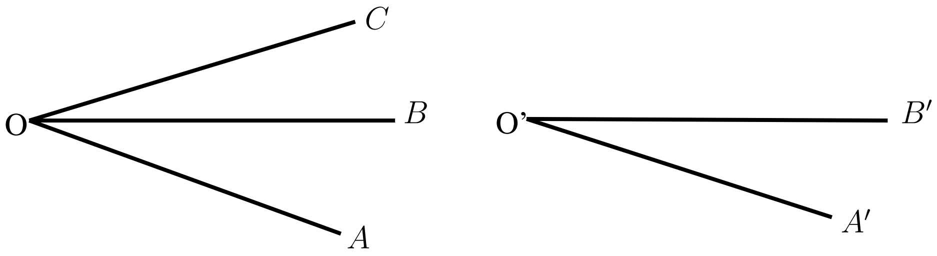

Figure 8.48: **Sum of any two angles**

Such an angle is obtained by a displacement which brings O on O$'$ and A at a point OA, followed or not by a rotation around OA.

Let us study for last case the sum of more than two angles:

The sum of several angles $\widehat{AOB}$, $\widehat{A'O'B'}$, etc., is by definition equal to the sum obtained by adding the first to the second, this sum to the third, and so on.

Given $\widehat{AOB}$ the first angle, $\widehat{BOC}$ the second angle, $\widehat{KOL}$ an angle equal to the last angle to add and adjacent to the previous one. The result of the sum will be $\widehat{AOL}$ augmented as many times of two flat angles that the plane was recovered during this operation. We easily see that this result does not depend on the order of angles $\widehat{A\text{O}B}$, $\widehat{A'\text{O}'B'}$ to add, etc.

D5. Two angles formed by two lines cut by a secant are named "alternate angles" if:

  (a) They are located on either side of the secant
  (b) They are located between the two lines
  (c) They are not adjacent angles

In the example below, the straight lines (X) and (Y) are cut respectively in A and B by the secant (S):

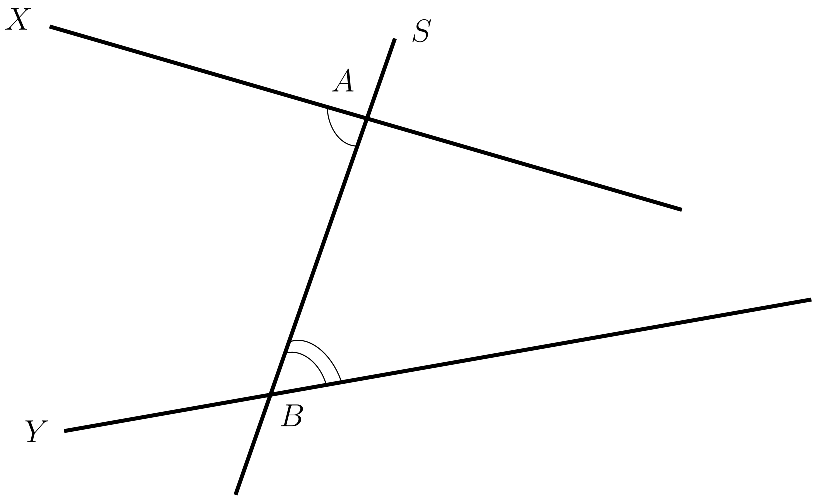

Figure 8.49: **Example of alternate angle**

and the two shown angles are alternate angles. In the case where (X) and (Y) are parallel, the alternate angles are equal.

It is also this which seems to have allowed Eratosthenes to deduce the circumference of the Earth from a purely geometrical way (thus it is not useless!)... even if there is quite good evidence that someone else did it long time before and that in reality Eratosthenes didn't do the measurements himself but just took the results reported in an old papyrus stored in the library of Alexandria[1].

✍**Example:**

So, according to the legend Eratosthenes used the observation he made on the shadow of two objects in two different places, Syene (now Aswan) and Alexandria, considered on the same meridian, the June 21 (summer solstice at his time) at local solar noon. It is at this precise time of the year that in the northern hemisphere the Sun (actually a G2V-type star, aka yellow dwarf) holds the highest position above the horizon. In a previous observation, Eratosthenes noticed that there was no shadow in a water well at Syene. Thus, at that moment, the Sun was vertical and its light shone directly the bottom of the water well. Eratosthenes noticed however that the same day at the same hour, an obelisk located in Alexandria formed a shadow. The Sun was no longer vertical and the obelisk had an off centered shadow. Eratosthenes considered as parallel the light rays of the Sun at any point on the Earth (considered as spherical). He deduced that the angle between the sunlight and the vertical was of 7.2 degrees.

---

[1] Indeed, the description of the experience - especially the position of the Sun at noon in a given city- leads to the conclusion that the actual experiment and record of this in Egypt occurred very likely 3,500 years before Eratosthenes time!!!

Eratosthenes then estimated the distance between Syene and Alexandria by using a bématiste which extrapolate upon the time of camel-day journey between the two cities: the distance achieved was estimated as 787.5 kilometers (measure very close to reality).

By the geometric theory of alternate congruent angles Eratosthenes proposed a simple figure: it consisted of a single circle having a central angle of 7.2 degrees which intercepts an arc (connecting Syene to Alexandria) of 800 kilometers.

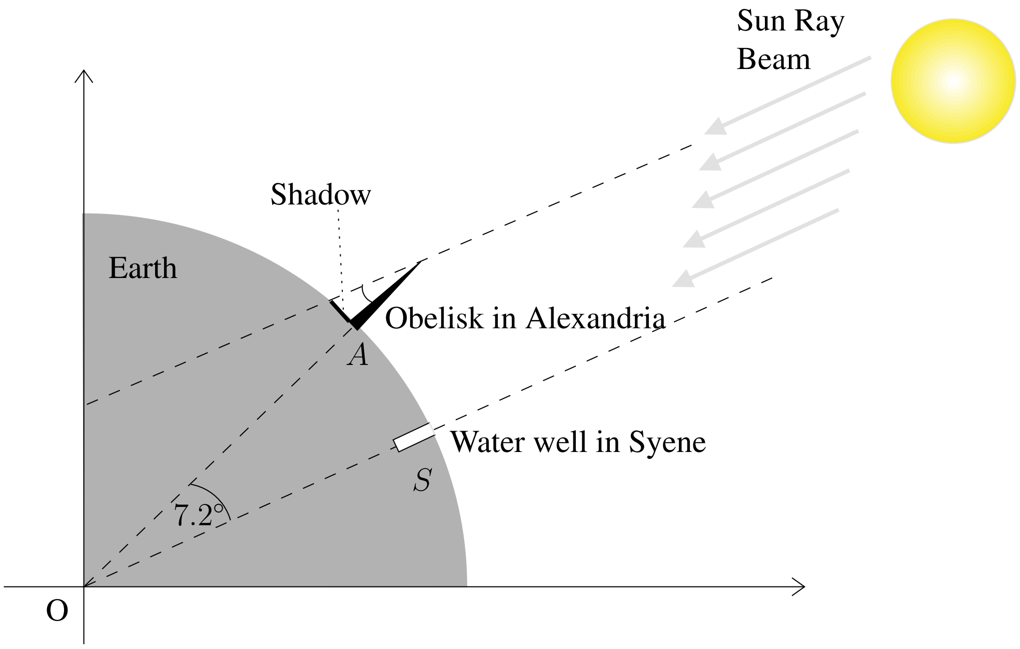

Figure 8.50: Alternate angle principle as used by Eratosthenes

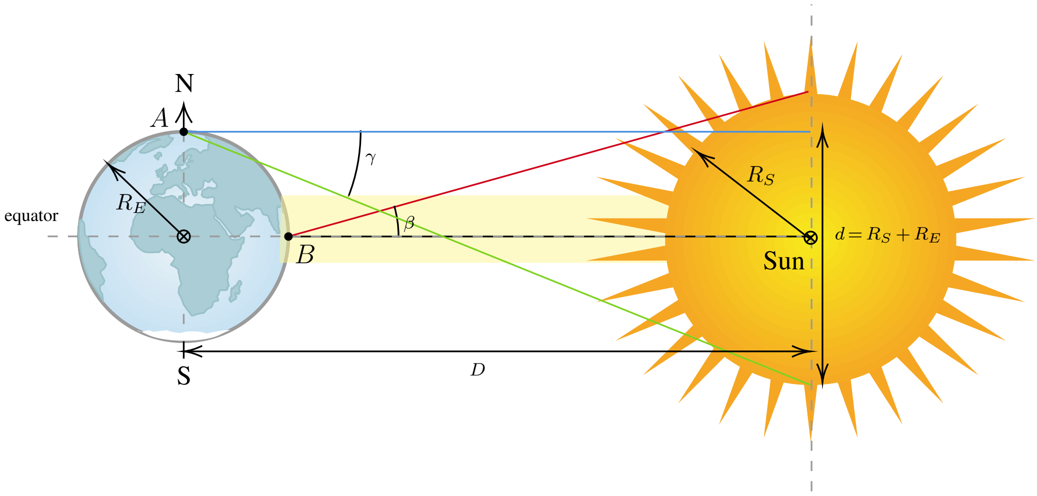
By the ratio in the circles (already known at that time), he calculated the circumference of the Earth was by a simple rule of three equal to $39,375$ kilometers. What was a remarkably accurate measurement for that time (the actual measures give an average of $40,075.02$ kilometers).

However...is the parallel rays assumption good enough? To answer let us consider the following figure:



Where we take for the radius of Earth $R_E \cong 6,371\,[\text{km}]$, for the radius of the Sun $R_S \cong 696,340\,[\text{km}]$ and for the average distance center-to-center of $D \cong 149,597,871\,[\text{km}]$ (see derivation in the section of Astronomy page 5218).

Let us compute first β (in degrees) that is half the angular size (angular diameter) of the Sun and corresponds to the most oblique angle a ray of light can be seen from the equator at the summer solstice (point B in the figure above):

$$\beta = \arcsin\left(\frac{R_S}{D - R_E}\right) \cong 0.26670959° \tag{8.2.37}$$

in most tables we can found $2 \cdot \beta \cong 0.5332°$.

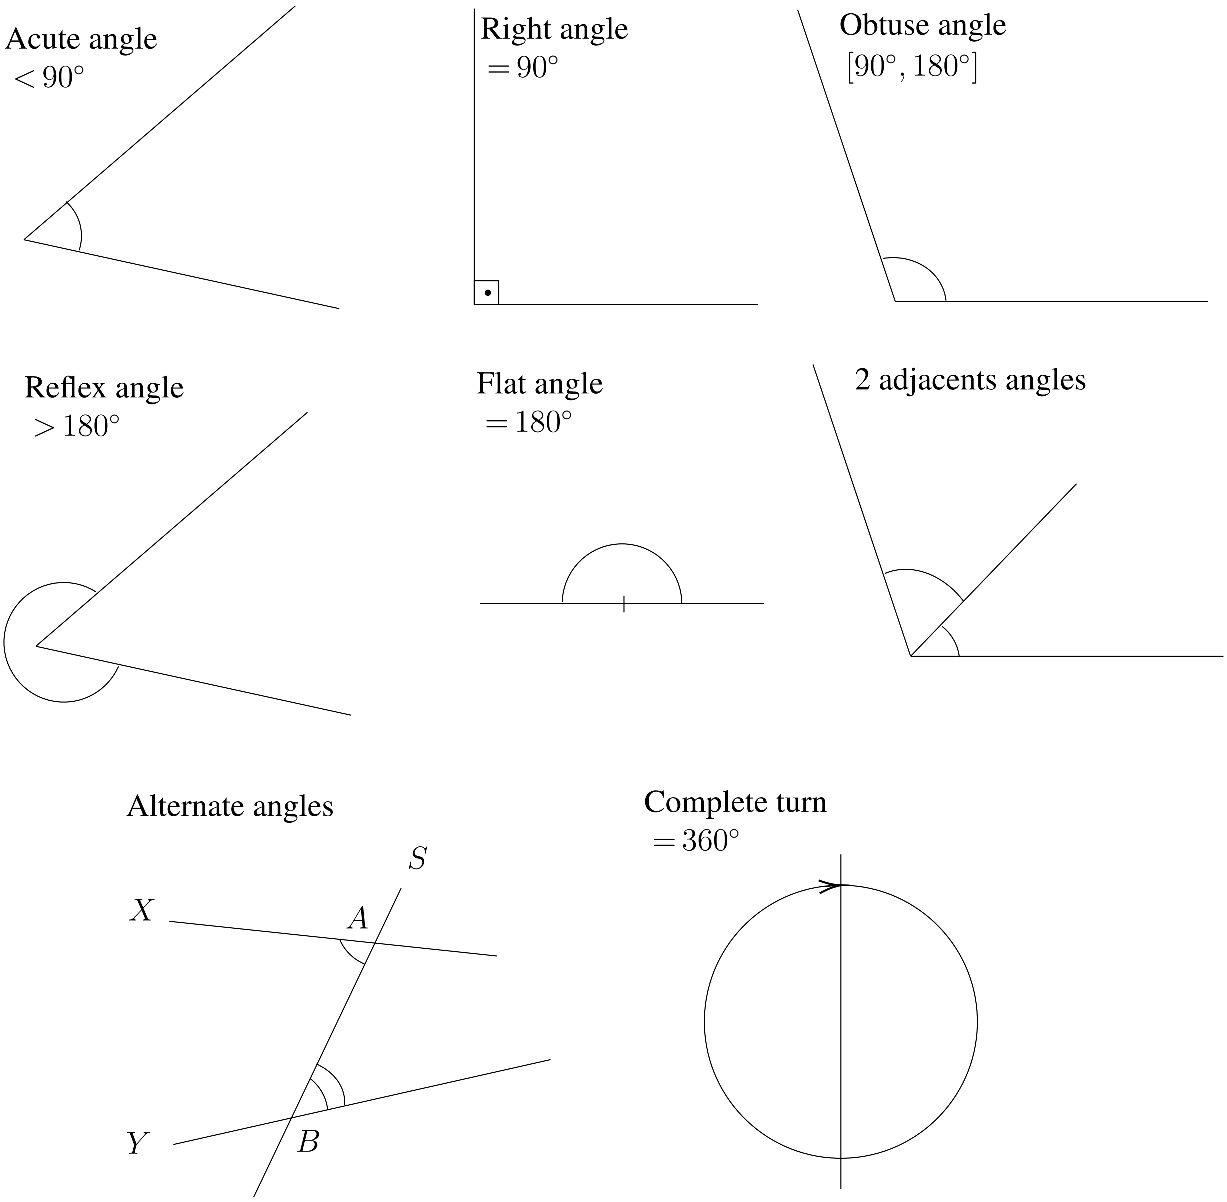
Now let us take the most extreme case in the figure above doing the same kind of calculation for the point A. For the latter we have:

$$\gamma = \arcsin\left(\frac{d}{D}\right) = \arcsin\left(\frac{R_S + R_E}{D}\right) \cong 0.269138339° \tag{8.2.38}$$

Hence in the worst case we have a difference of $0.00242875°$ between both most extreme angles in people look on the same point of the Sun. Or if we add up (people on point A and B look in opposite direction) we have $\beta + \gamma = 0.5358°$. So whatever the scenario we take $\beta - \gamma = 0.00242875°$ or $\beta + \gamma = 0.5358°$ the claim - or approximation - of parallel rays is quite acceptable.

Caution!!! Eratosthenes calculation is not an experimental evidence that the Earth is a geoid (spherical shaped like!). Indeed, the calculations would lead to the same result if the Earth was flat, toroidal or many other non-spherical shapes! Better direct experimental evidence are: 1) Satellites photos, 2) Astronauts direct observations 3) The observation of low-pressure weather systems that rotate anti-clockwise in the northern hemisphere due to the Coriolis effect 4) Foucault's pendulum shifts with time 5) The observation that stars seen at southern hemisphere are not the same as those seen at the northern hemisphere etc.

Let us do a summary of most type on angles that the reader mus remember:



Acute angle
$< 90°$
Right angle
$= 90°$
Obtuse angle
$[90°, 180°]$
Reflex angle
$> 180°$
Flat angle
$= 180°$
2 adjacents angles
Alternate angles
S
X
A
Y
B
Complete turn
$= 360°$

Figure 8.51: **Angle types summary**

8.2.3.2.1 Angle Measurements

We have defined the equality and the sum of two or more angles. These definitions meet the conditions of the same quantities variables we have already seen previously.

So let us choose arbitrarily an angle of the plane $\widehat{aob}$, which will bet the unit angle for the plane. The measurement of the ratio:

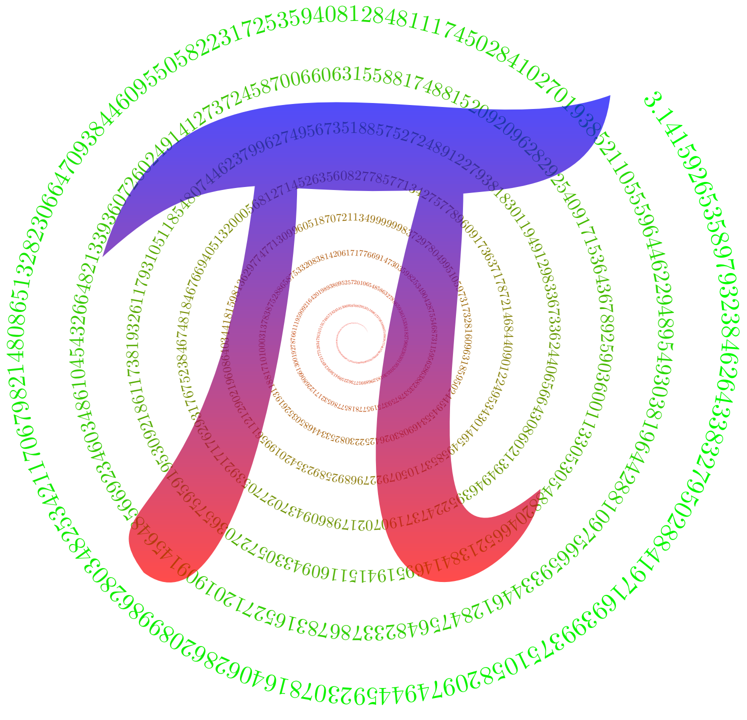
$$\frac{\widehat{AOB}}{\widehat{aob}} \tag{8.2.39}$$

proceed as it has been explained previously during our study of the quantities of the same species, will be a positive number denoted most of time by the greek letters α or θ named by definition the "angle measurement $\widehat{AOB}$, with the selected unit $\widehat{aob}$".

We denote by the lowercase Greek letter "pi" the irrational number:

$$\boxed{\pi = 3.14159265358979323846264338327950288419716939\ldots} \tag{8.2.40}$$

which is by definition the measurement value of a "flat angle" or also named "plane angle" (we have already see where this value comes from in the section of Trigonometry).



The reader can refer to the section of Numerical Methods to see another definition of π based on the circumference of the circle and based on the Archimedes algorithm (see page 6298).

Remark

As all angles of the plane are smaller than two flat angles, the number θ (which is the measurement of $\widehat{AOB}$) must be less than 2π.

Having defined the flat angle, we can now define other types of commonly used angles:

Definitions (#8.2.327):

D1. We name "right angle" any angle equal to half of a flat angle.

D2. Two angles are "perpendicular angles", denoted by the symbol $\perp$, when they are both rights and adjacent.

D3. We name "acute angle" any angle less than a right angle and "obtuse angle" any angle greater than a right angle.

D4 We name "oriented angle" or "vector angle", the angle between two vectors or lines (see section Vector Calculus page 1797) having same origin and which value measured counter-clockwise will be taken as positive and negative if taken in the clockwise direction.

The best known example of oriented angle is the trigonometric unit circle:

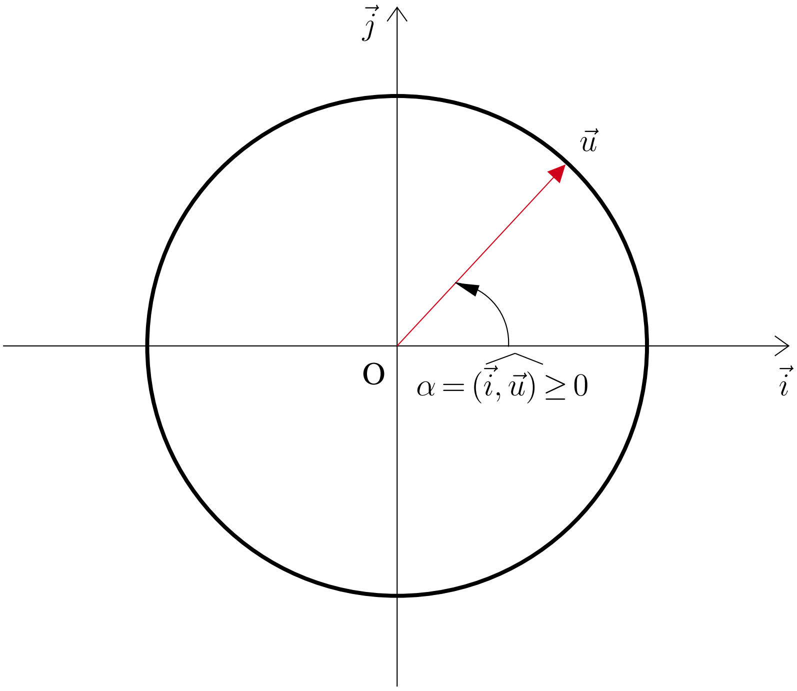


Figure 8.52: **Positive or null oriented angle**

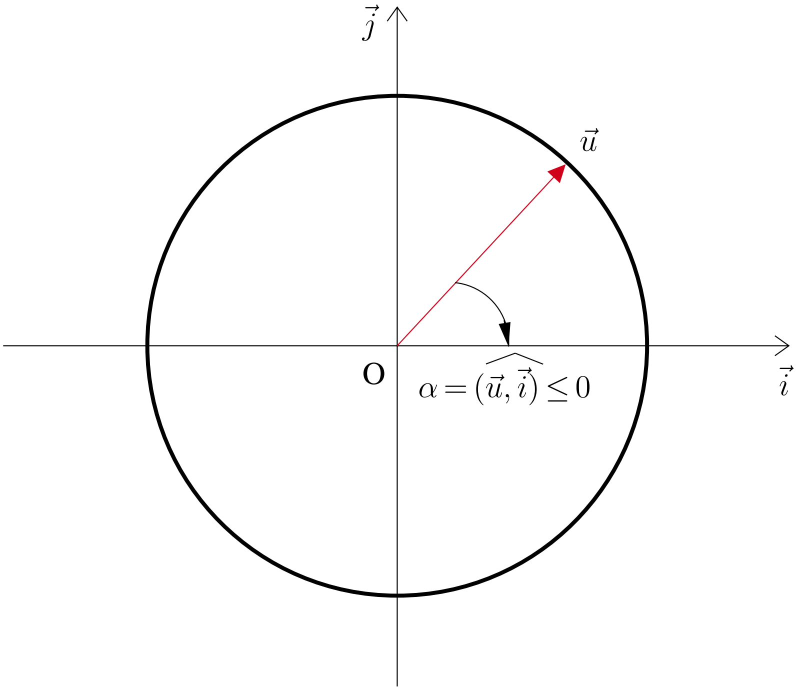


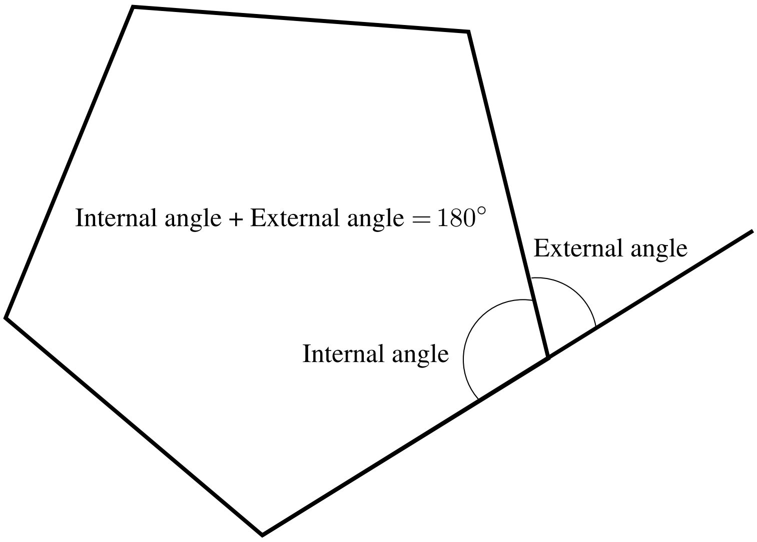
$\vec{j}$
$\vec{u}$
O
$\alpha=\widehat{(\vec{u},\vec{i})}\leq 0$
$\vec{i}$

Figure 8.53: **Negative or null oriented angle**

D5. We say that two angles are "additional angles" or "supplementary angles" when their sum is equal to two right angles (i.e. a flat angle).

D6. We say that two angles are "complementary angles" when their sum is equal to a right angle (thus two complementary angles are always right...).

The "internal angle" and "external angle" of a regular polygons are complementary angles as by construction:



Internal angle + External angle $=180^\circ$
External angle
Internal angle

Figure 8.54: **Internal + External angle (source: Wikipedia)**

Let us now consider the symbols α,β,γ as the measurements of several angles $\widehat{AOB}$, $\widehat{BOC}$, $\widehat{COD}$.

We will not insist on the obvious fact that the equalities $\widehat{AOB} = \widehat{BOC}$ or $\alpha = \beta$ are equivalent and thus the inequalities $\widehat{AOB} < \widehat{BOC}$, or $\alpha < \beta$. These common sense remarks are applied whenever the same species of quantities will have been measured, of course with the same unit!

However, we insist that, according to the definition of the sum of several angles, $\alpha + \beta + \gamma$ is the measure of the angle $\widehat{AOD}$ increased as many times of two flat angles π that the plane was covered during the operations of addition:

$$\alpha + \beta + \gamma = \widehat{AOD} + 2n\pi \qquad (8.2.41)$$

The relative integer n which is introduce in this calculation has a value that can be specified, but that has no importance for the mathematician or physicist, as we will see later. We thus do not decide not to write the $2n\pi$ in geometry (as it will be always implicit). Also, we decide by convention to write:

$$\widehat{AOD} = \theta \qquad (8.2.42)$$

So we have:

$$\alpha + \beta + \gamma = \theta \qquad (8.2.43)$$

the notation convention means that θ is the measurement of the angle $\widehat{AOD}$ if we have $0 \leq \theta < 2\pi$.

If θ is greater than 2π, this equality means that the measurement of the angle $\widehat{AOD}$ is $\theta - 2n\pi$, n being a relative integer so that we have $0 \leq \theta - 2n\pi < 2\pi$.

Remarks

R1. If $\theta > 2\pi$ there is only one unique positive integer n and only one, as we have $0 \leq \theta - 2n\pi < 2\pi$, that is to say:

$$\frac{\theta}{2\pi} - 1 < n \leq \frac{\theta}{2\pi} \qquad (8.2.44)$$

because the two numbers $(\theta/2\pi) - 1$ and $\theta/2\pi$ are positive and different from 1.

R2. Saying that θ is the measurement of the angle $\widehat{AOD}$ suppose that we have $0 \leq \theta < 2\pi$ and leads to the equality $\widehat{AOD} = \alpha$. But write $\widehat{AOD} = \alpha$ does not necessarily mean that θ is the measurement of $\widehat{AOD}$; it is necessary for this that we have $0 \leq \theta < 2\pi$.

8.2.3.2.2 Units of Angle Measurements

We have define the flat angle to be equal to π without specifying the unit. This is what we will now apply to do. There are (still and sadly) several units of angle measurements which most important and common one are listed below:

Definitions (#8.2.328):

D1. We name "degree" the 180th part of a flat angle.

Remark

The original motivation for choosing the degree as a unit of rotations and angles is unknown.

Many old former are still made in degrees (and still today in some areas of physics/astronomy). The sub-multiple of the degree is the: "Sexagesimal minute" equal to the 60th of 1 degree, and the "Sexagesimal second" is equal to the 60th of the sexagesimal minute.

✍**Example:**

The value:

$$\theta = 236^\circ 20' 40''$$

will be read as two hundred thirty six degrees, twenty minutes and forty two seconds.

The conversion from degrees to fractional decimal angles is quite easy:

$$\begin{aligned} 236.345^\circ &= 236^\circ + 0.345^\circ = 236^\circ + 0.345^\circ \frac{60'}{1} \\ &= 236^\circ + 20.7' = 236^\circ + 20' + 0.7' \frac{60''}{1'} \\ &= 236^\circ 20' 42'' \end{aligned}$$

Most countries around the world sadly still use today degrees in Kindergarten and Highschools but without making use of the notation of minutes and seconds (not very convenient for pedagogical reasons).

D2. As we have already see it in the section of Trigonometry, we name "radian" (denoted [rad]) the plane angle described by a secant to a circle, passing through its center, such that the arc as defined by the horizontal axis through the center of the circle and the secant be of equal length of the radius of the circle:

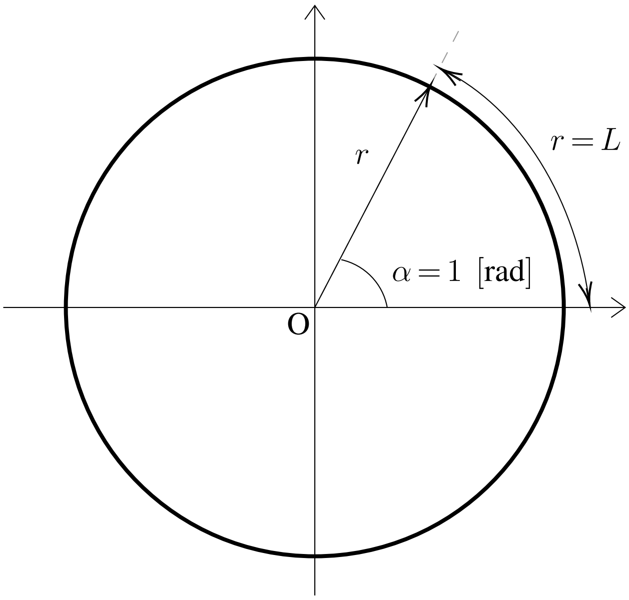


Figure 8.55: **Geometric definition of the radian**

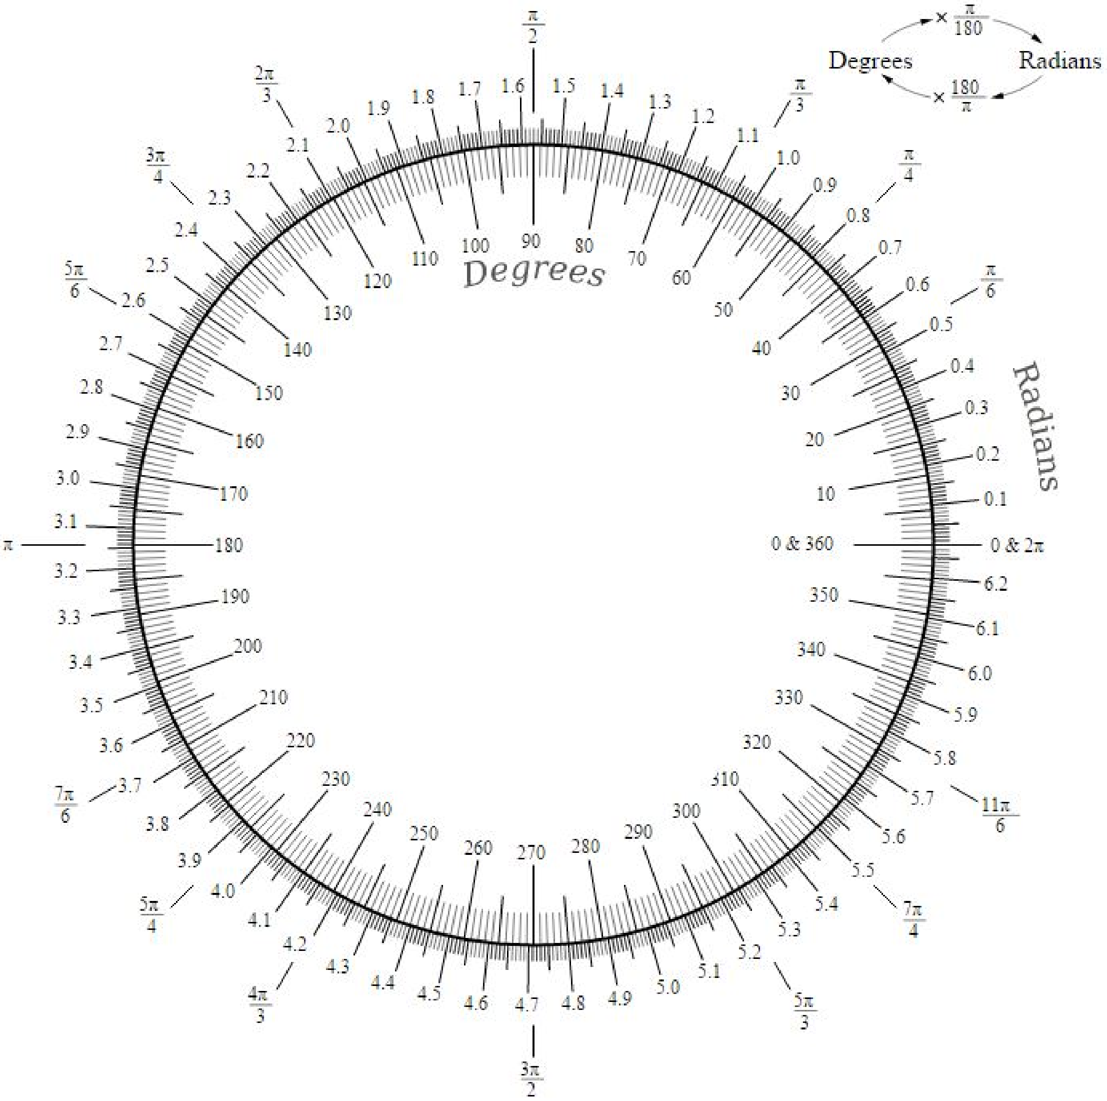
In most mathematical work beyond practical geometry, angles are typically measured in radians rather than degrees. This is for a variety of reasons; for example, the trigonometric functions have simpler and more "natural" properties when their arguments are expressed in radians (see section Trigonometry page 2503).

One complete turn ($360°$) is equal to 2π radians, so a half turn of $180°$ is equal to π radians, or equivalently, the degree is a mathematical constant given by:

$$\boxed{1° = \frac{2\pi}{260} = \frac{\pi}{180}} \qquad (8.2.45)$$

Thus, in radians, a flat angle is equal to π and all other angles are real multiples of this constant.



Degrees
Radians
$\times\frac{\pi}{180}$
$\times\frac{180}{\pi}$
Degrees
Radians
0 & 360
0 & 2π
$\frac{\pi}{2}$
π
$\frac{3\pi}{2}$

Figure 8.56: **Degrees-Radians conversions figure (source: Wikipedia)**

D3. We name "grad" the 200th part of the flat angle.

The grade is also an old angle unit. Its sub-multiples are: the "centesimal minute," equal to 100th of one grad, and the "centesimal second", equal to one hundredth of the centesimal minute.

The value:

$$\theta = 236.345\,[\text{gr}]$$

will be read as two hundred thirty six grads, eighteen minutes and five second.

Here are some typical angles values:

Value [degrees]	**Description**
0°	A flat surface
0.0000305°	Average angular diameter of Pluto
0.000632°	Average angular diameter of Neptune

0.00096°	Average angular diameter of Uranus
0.0023°	Average angular diameter of Mercury
0.0043°	Angular diameter of Hubble deep field
0.0047°	Average angular diameter of Saturn
0.00645°	Average angular diameter of Mars
0.012°	Average angular diameter of Jupiter
0.017°	Average resolvable diameter by the human eye
0.529°	Actual average angular diameter of the Sun
0.53°	Actual average angular diameter of the Moon
1.4°	Earth precession angle by century
3.16°	Actual angular diameter of Andromeda Galaxy
5.33°	Actual angular diameter of the small Magellanic cloud
5.14°	Moon-Earth orbital angle
10°	Actual angular diameter of large Magellanic cloud
15°	Typical airplane take-off angle
19.3°	Steepwest street in the World: Baldwin Street - Dunedin, New Zealand
20°	Width of spread out hand with arm stretched out
23.44°	Earth's obliquity
30°	Incline of many laptop stands
38°	Actual angular diameter of Gum Nebula
45°	Staircase handrail
48°	Steepest funiclar in the World: Stoosbahn - Switzerland
60°	The angle between spokes in a 6-spoke wheel
90°	A perpendicular
$\gtrsim 100°$	Magellanic stream angular diameter
125°	Human binocular vision range
360°	Milky way angular diameter

Table 8.4: **Some common angles values**

8.2.3.2.3 Bisector

Now that we know how to compare, add and measure angles we will be able to look at an important concept in geometry that is the one of "bisection" and some relative properties that we will reuse later for quite important theorems.

Definitions (#8.2.329):

D1. We name "bisector" the straight line that divides an angle into two equal parts.

D2. We name "half-bisector" the segment that divides an angle into two equal parts and start at the origin of the angle.

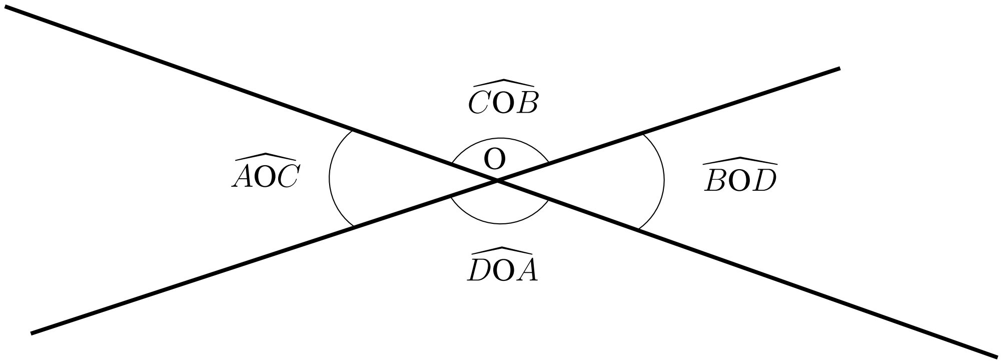
D3. We name "line segment bisector" the (infinite) straight line that passes through the mid-point of a segment.

Particularly important is the "perpendicular bisector" of a segment, which, according to its name, meets the segment at right angles.

Two straight lines AB and CD intersecting on a point O form as we already know intuitively, four angles:

$$\widehat{AOC},\widehat{COB},\widehat{BOD},\widehat{DOA} \tag{8.2.46}$$

The angles $\widehat{AOC}$, $\widehat{BOD}$, as well as the angles $\widehat{COB}$, $\widehat{DOA}$ whose sides are opposite, are known as "opposing angles by the top".



Obviously, if θ is the measurement of the angle $\widehat{AOC}$, the measurement of the adjacent angle $\widehat{COB}$ is $\pi-\theta$. That of the angle $\widehat{DOB}$ adjacent to the previous is $\pi-(\pi-\theta)$, that of $\widehat{DOA}$ is $\pi-\theta$.

Given OE the half-bisector of the angle $\widehat{AOC}$, OG that of the angle $\widehat{COB}$, OF that of the angle $\widehat{BOD}$, OH that of the angle $\widehat{DOA}$, we have:

$$\widehat{COE}=\frac{\theta}{2} \qquad \widehat{COG}=\frac{\pi-\theta}{2} \tag{8.2.47}$$

and consequently:

$$\widehat{GOE}=\frac{\pi}{2} \tag{8.2.48}$$

We would have also same:

$$\widehat{GOF}=\widehat{FOH}=\widehat{HOE}=\frac{\pi}{2} \tag{8.2.49}$$

We summarize as following all these results as well as measurement properties:

P1. Two opposite angles that share the same top are equals.

P2. Two opposite angles that share the same top have the same bisector.

P3. The bisectors of two additional adjacent angles are rectangular bisector.

P4. The bisectors of angles formed by two secants are two perpendicular lines (right angles).

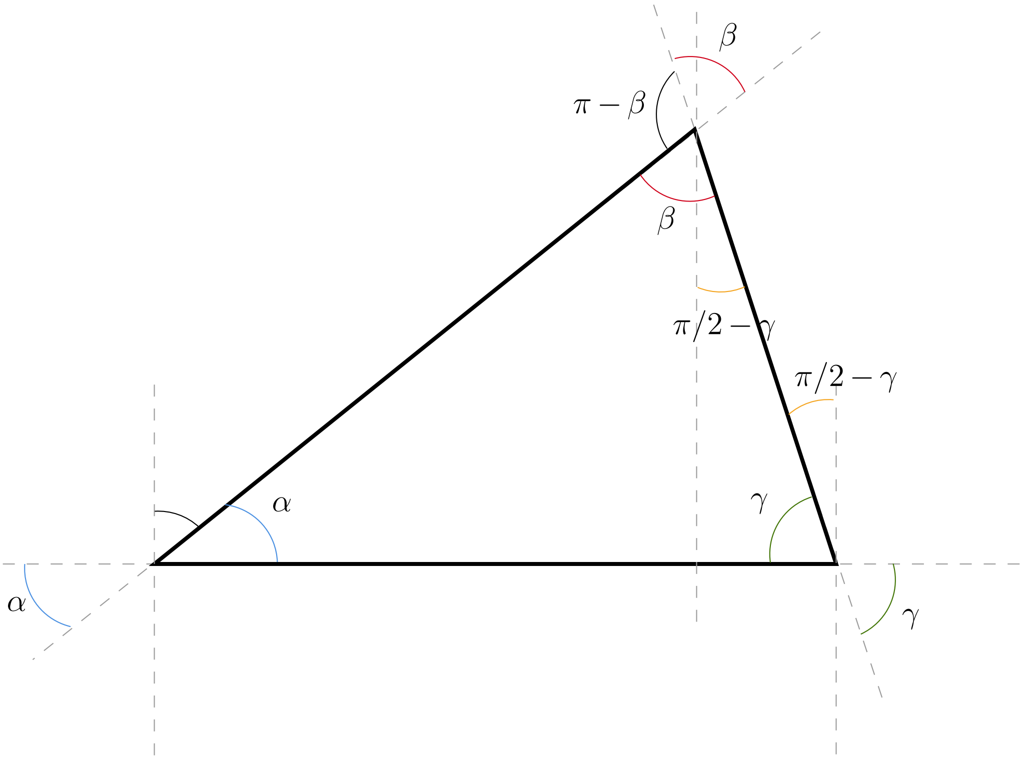


Figure 8.57: **Typical useful triangle angles in the study of Statics**

8.2.3.3 Triangles

We have study so far until now the concept of dimensions, point, straight segment, straight line, angle and of open (infinite) plan. However, a plane may be defined by several lines to thereby obtain geometric plane shapes the simplest of which may be regarded as triangles (for many other shapes see the section Geometrical Shapes at page 2886).

Definition (#8.2.330): We name "triangle" a figure (see below) formed by three segments (or lines) AB, BC, CA, the points A, B, C being not aligned. The segments AB, BC, CA, are the "sides" of the triangle. The points A, B, C are the "vertices" of the triangle. The salient angle $\widehat{BAC}$, which contains all the points of BC, is named angle $\hat{A}$ of the triangle and BC is then named the "opposite side".

Remark

We use the notation $\hat{A}$ when no confusion is possible. If necessary we use the notation $\widehat{BAC}$ with the same meaning.

There are 6 elements in a triangle, namely: three angles $\hat{A}$, $\hat{B}$, $\hat{C}$ and three finite sides $\overline{AB}$, $\overline{BC}$, $\overline{CA}$ that are most of time simply denoted by AB, BC, CA.

We will designate by $a=BC$, $b=AC$, $c=AB$ the measured lengths of the sides with the same unit of measurement, and obviously by $\hat{A}$, $\hat{B}$, $\hat{C}$ the measurements of the angles.

Theorem 8.5. The sum of the angles of a plane triangle is always equal to π radians (or 180°). The proof is quite simple and is named the "angle sum theorem".

Proof 8.5.1. In the figure below, ABC is any triangle, and D is the parallel to $\overline{BC}$ passing through A. We observe:

1. The blue angles have the same amplitude (value) because they are alternate angles (the segment $\overline{BC}$ and the line D being parallels).
2. Also, the green angles have the same amplitude (value) because they are alternate angles[2].
3. We notice that the sum of the angles blue + red + green are equal to a flat angle on A.

From the equalities seen in (1) and (2) previously, we deduce that:

$$\vec{A}+\vec{B}+\vec{C}=\pi=180^\circ \tag{8.2.50}$$

---

[2] If two lines are parallel then their alternate interior angles are equal. If the alternate interior angles of two lines are equal then the lines must be parallel. This is for reminder the "Z theorem".

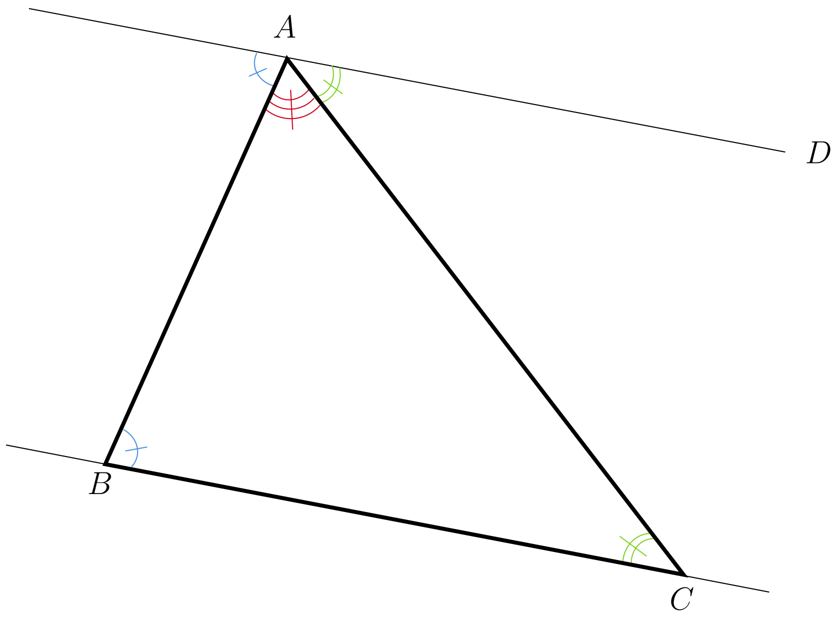

Figure 8.58: **Sum of angles of a plane triangle**

This proof is valid regardless the type of triangle drawn in the plane.

■ Q.E.D.

As for all other shapes that we will see in this section, the calculations of the perimeter and area (surface) are given in the section of Geometric Shapes page 2888.

8.2.3.3.1 Equal Triangles (congruent triangles)

Definition (#8.2.331): We say that two triangles are "equal triangles" when we can by movement or by a reversal or both combined, superimpose all vertices of the first triangle with that of the second. Then we say also that the triangles are "homologous triangles" or "congruent triangles".

If a triangle ABC is congruent to a triangle DEF, the relation can be written mathematically as:

$$\boxed{\triangle \text{ABC} \cong \triangle \text{DEF}} \tag{8.2.51}$$

From this definition, it comes that two triangles are congruent when either the following two properties are satisfied:

P1. They have one equal side and two equal angles.

Proof 8.5.2. So we state that two triangles have equal side $\overline{BC} = \overline{B'C'}$ between two equal angles $\hat{B} = \hat{B}'$,$\hat{C} = \hat{C}'$ are equal.

In other words, if 2 triangles have 2 equal angles 2 by 2, then the 3rd angles are equal too. That said we can now take as equal side the one that is located between the 2 equal angles without loss of generality.

Since $\overline{BC}=\overline{B'C'}$ (see figure below), there is a movement which brings B' to B and C' in C. This movement brings A' on A_1 located on the same side relatively to the segment $\overline{BC}$, or on A_2 symmetric of A_1 relatively to this same segment.

The two segments $\overline{BA}$ and $\overline{BA_1}$ do by hypothesis, with $\overline{BC}$ the same angle $\hat{B}=\hat{B}'$. As they are by construction on the same side of $\overline{BC}$, they are merged. The both segments $\overline{CA}$ and $\overline{CA_1}$ are merged for the same reason and because $\hat{C}=\hat{C}'$. A_1 is then merged with A. The two triangles ABC, $A'B'C'$ are then indeed congruent.

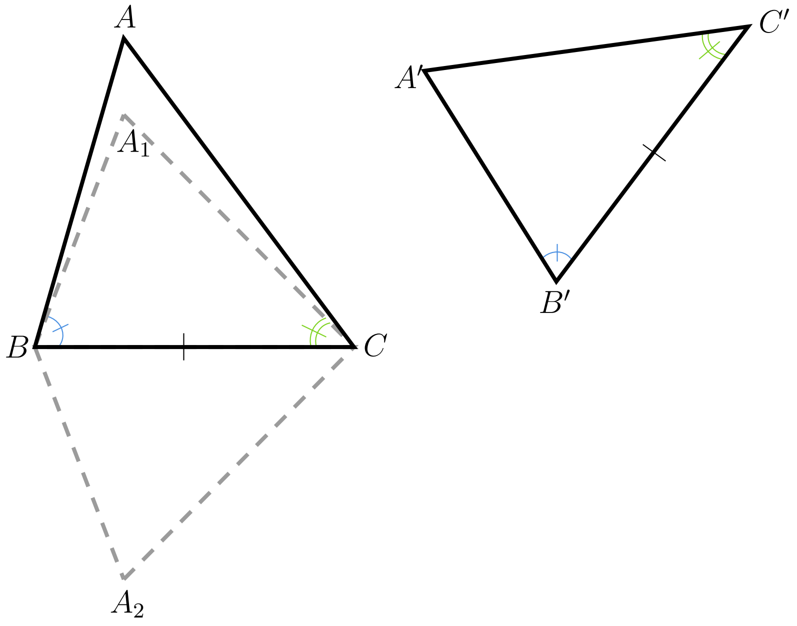

Figure 8.59: **Two triangles having equal side and two equal angles**

■ Q.E.D.

This result is named sometimes the "angle-side-angle theorem".

P2. They have a same angle between two sides of equal length.

Proof 8.5.3. So we state that two triangles with an equal angle $\hat{A}=\hat{A}'$ between two equal sides $\overline{AB}=\overline{A'B'}$ and $\overline{AC}=\overline{A'C'}$ are equal.

Since $AB=A'B'$ (see figure below) there exist a shift located relatively to $\overline{AB}$ at the same side as the point. If it brought it on C_2 symmetric of C_1 with respect to $\overline{AB}$, a half turn around the $\overline{AB}$ would take it on C_1. The segments $\overline{AC}$ and $\overline{AC_2}$ located on the same side of $\overline{AB}$ do, by hypothesis the same angle with $\overline{AB}$, since $\hat{A}=\hat{A}'$. They are then merged. The hypothesis $\overline{AC}=\overline{AC_1}$ then makes us conclude that C_1 and C coincide. The two triangles ABC, $A'B'C'$ are then congruent.

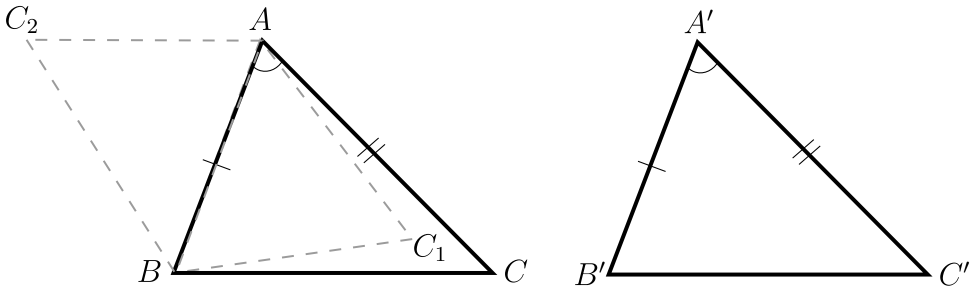

Figure 8.60: **Displacement showing the equality of the 2 triangles**

■ Q.E.D.

Corollary 8.5.1. As corollary we have that two triangles are congruent if their three sides are equal. This is named sometimes the "SSS (side-side-side) theorem".

Now about drawing symbols, it is common to represent various equal angles or equal sides in triangle as following :

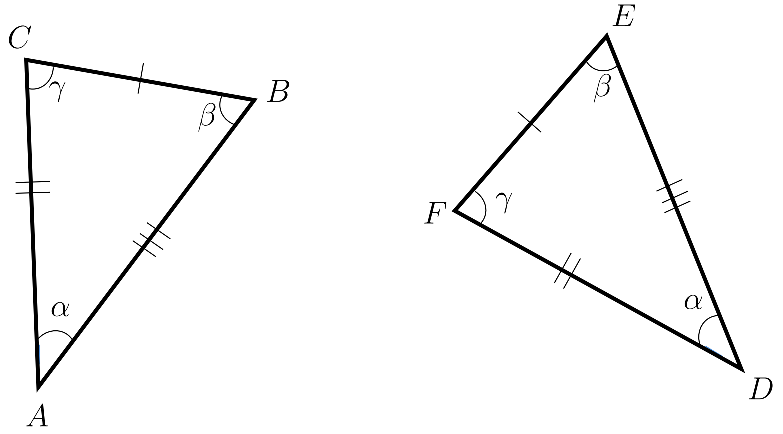

Figure 8.61: **First typical notation for congruent triangles**

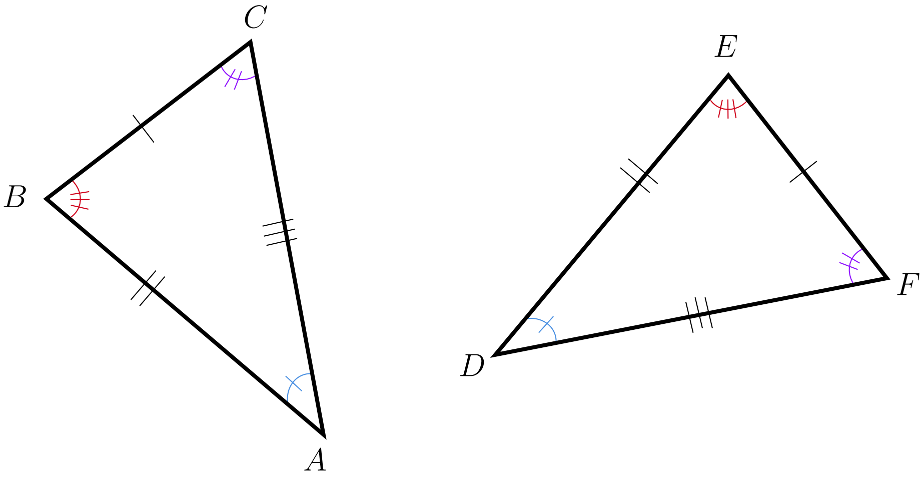

Figure 8.62: **Second typical notation for congruent triangles**

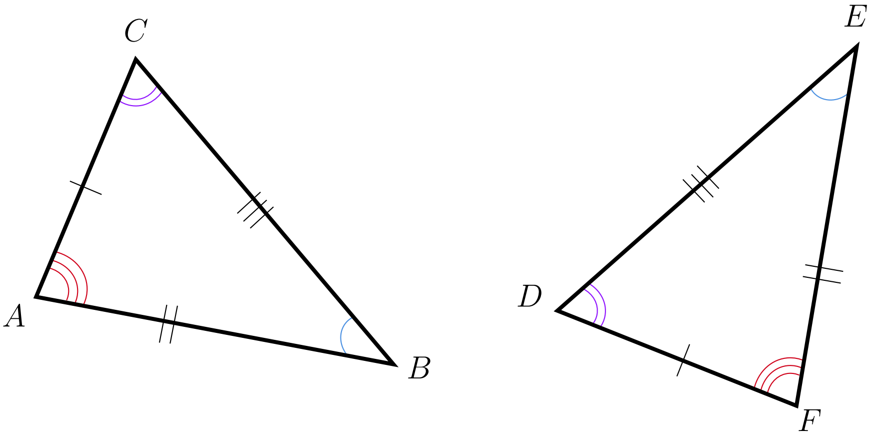

Figure 8.63: **Third typical notation for congruent triangles**

8.2.3.3.2 Isosceles Triangles

Definition (#8.2.332): We say that ABC is an "isosceles triangle" when two of its sides AB and AC are equal ("iso" meaning "same"). The third side BC is then named the "base" of the triangle.

Remark

We say that a triangle is "scalene" when it has three unequal sides.

Definition (#8.2.333): We name "mediator" of a segment $\overline{BC}$, the perpendicular to $\overline{BC}$ at point H of this segment, middle of $\overline{BC}$.

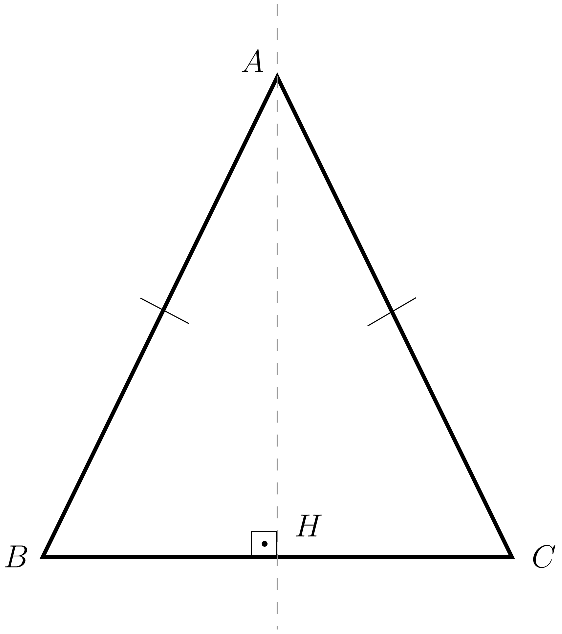

Figure 8.64: Representation of the mediator in isosceles triangle

Theorem 8.6. In an isosceles triangle ABC as shown above, the angles $\hat{B}$ and $\hat{C}$ opposed to the equal sides are equal.

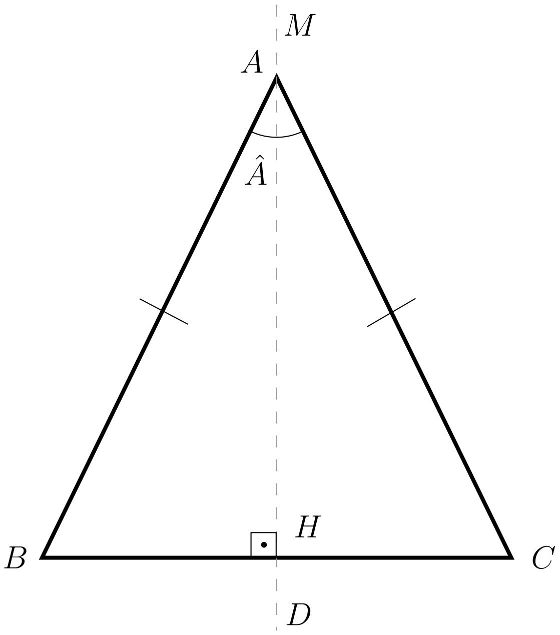
Proof 8.6.1. The both (right) triangles BAH and CAH defined by the bisector of $\widehat{A}$ have an equal angle $\widehat{BAH}=\widehat{CAH}$ by construction between two equal sides: $\overline{AH}$ that is the shared (common) side and $\overline{AB}=\overline{AC}$ by hypothesis. As the angles $\widehat{BHA}=\widehat{CHA}$ and rights and equals and that the sum of angles of a triangle is equal to a straight angle (180° or π radians), then the angles $\widehat{HBA}$ and $\widehat{ACH}$ are equal.

■ Q.E.D.

Remark

This latest proof is one to which refers the comic Logicomix on page 55 and it is this type of proof by logical induction which would have brought the young Bertrand Russell to became interested in logic to later become one of the most famous logicians in modern history.

Theorem 8.7. In an isosceles triangle ABC as shown above the mediator of $\overline{BC}$ and the bisector of the angle $\hat{A}$ coincide (figure below):



In other words, the locus of equidistant points M (at same distance) between of two given points B and C is given by the bisector (D) of segment $\overline{BC}$.

Remark

In geometry, a "locus" is a set of points (commonly, a line, a line segment, a curve or a surface), whose location satisfies or is determined by one or more specified conditions. More formally we name "locus" of a point M, subject to some constraints (conditions), all positions occupied by this point M that still satisfy the constraints (conditions).

Proof 8.7.1. We will prove first that any point of the locus is on the line (D) and afterwards that any point of (D) is a point of the locus.

1. Any point of the locus is on the line (D):

   In other words, the assumption, in the figure above, that $\overline{MB}=\overline{MC}$ implies that M is the mediator of $\overline{BC}$. Indeed, if $\overline{MB}=\overline{MC}$, the triangle MBC is isosceles and the top M is on the mediator of $\overline{BC}$ (that coincides as we know with the bisector).

2. Any point of (D) is a point of the locus:

   This means that if M is on the mediator of $\overline{BC}$, we have $\overline{MB}=\overline{MC}$. Indeed, if M is on the line (D) that meets in H, midpoint of $\overline{BC}$, the line BC, the triangles MHB, MHC are then equal (second case of equality: $\widehat{BHM}=\widehat{CHM}$ because these angles are straight, $\overline{HM}$ common; $\overline{HB}=\overline{HC}$ because H is the midpoint of $\overline{BC}$): the sides $\overline{MB}$, $\overline{MC}$ are then also equal and we have indeed $\overline{MB}=\overline{MC}$. Therefore point M is indeed a point of the locus.

■ Q.E.D.

Using this theorem we can state another one:

Theorem 8.8. By taking a point A outside a line $\overline{BC}$, we can draw to this line a single perpendicular (or in other words: to a given point outside of a given line we can draw one and only one perpendicular line).

This is an equivalent to the Euclid's fifth postulate and a way to build an isoceles triangle as the apex is on the perpendicular of the base.

Proof 8.8.1. The proof is done in two steps:

1. There exist a perpendicular line:

   Indeed, given a triangle ABC, let us subject this triangle to half a turn around BC (horizontal symmetry) as in the figure below:

   
   The apex A comes in A' symmetrical by definition, relative to $\overline{BC}$. Since the figures, ABC and $A'BC$ are equal, $\overline{AB}=\overline{A'B}$ and $\overline{AC}=\overline{A'C}$.

   $\overline{BC}$ is then the mediator of $\overline{AA'}$ and the lines $\overline{BC}$ and $\overline{AA'}$ are perpendicular. $\overline{AA'}$ is therefore well perpendicular to $\overline{BC}$ passing through A.

2. The perpendicular line is unique:

   Given $\overline{AH}$ a perpendicular drawn from A to $\overline{BC}$, it meets the line $\overline{BC}$ on a point H that is different from either B or C.

   Let us Suppose that H is different from B. The angles $\widehat{AHB}$, $\widehat{A'HB}$ which are deduced from each other by rotation, are equal, and as each of them is a right angle, the angle $\widehat{AHA'}$ is a flat angle. The line $\overline{AH}$ thus coincides with the straight line $\overline{AA'}$ and is therefore the only perpendicular to $\overline{BC}$ which passes through the apex A.

■ Q.E.D.

Definitions (#8.2.334):

D1. We name "orthogonal projection" from point A on a line $\overline{BC}$ the point H point where the perpendicular drawn from A at this line meet H. The point H is also named the "foot" of the perpendicular.

We have already see the vector version of this projection in the section of Vector Calculus and that it was denoted by $\text{proj}_{\overline{BC}A}$.

D2. We name "geometrical distance" from A to $\overline{BC}$ the length of the segment $\overline{AH}$.

Since in the previous figure $\overline{BC}$ is the mediator of $\overline{AA'}$, H is the midpoint of $\overline{AA'}$. So: A point A and its symmetrical point A' are with respect to a straight line (D) are characterized by the following two properties that we will not prove as we consider them sufficiently intuitive:

P1. $\overline{AA'}$ is perpendicular to (D)

P2. The middle of $\overline{AA'}$ is on (D)

The line $\overline{AB}$, which connects the apex A to a point of the straight line $\overline{BC}$, other than the foot H of the perpendicular drawn from A to this line, is named an "oblique line". The point B being named the "oblique foot".

8.2.3.3.3 Equilateral Triangles

Definition (#8.2.335): A triangle ABC is say to be an "equilateral triangle" when all its three sides are equal. In the familiar Euclidean geometry, equilateral triangles are also equiangular; that is, all three internal angles $\hat{A},\hat{B},\hat{C}$ are also congruent to each other and are each equal to $\pi/3$ (60°). They are regular polygons (see definition further below), and can therefore also be referred to as "regular triangles":

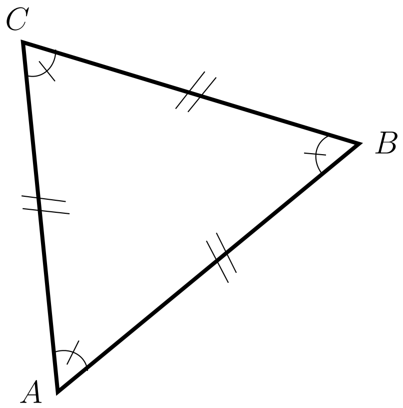


Figure 8.65: **Equilateral triangle**

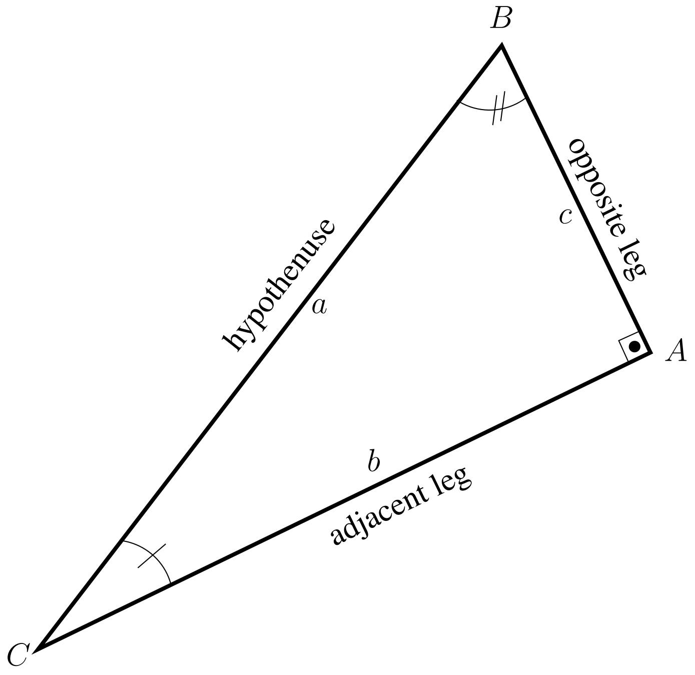
As for all other shapes that we will see in this section the calculation of the perimeter and area (surface) are given in the section of Geometric Shapes at the page 2886.

8.2.3.3.4 Right Triangle

Definition (#8.2.336): A "right triangle" (American English) or "right-angled triangle" (British English) is a triangle in which one angle is a right angle (that is, a 90° angle or $\pi/2$ [rad]). The relation between the sides and angles of a right triangle is the basis for trigonometry!

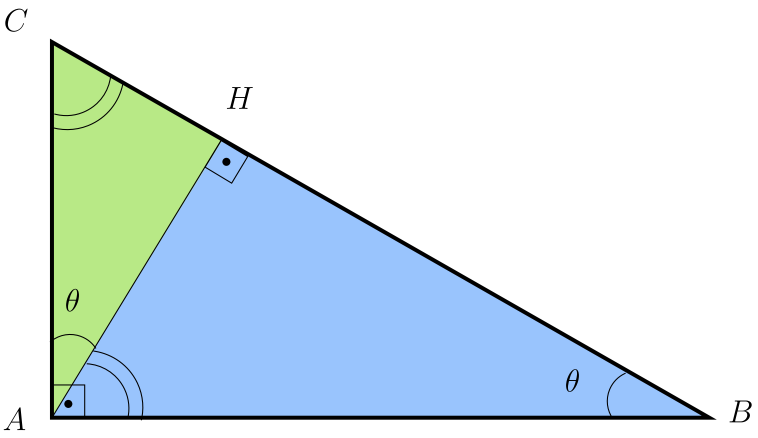
The side opposite the right angle is named the "hypotenuse" (side c on the figure). The sides adjacent to the right angle are named "legs". Side a may be identified as "the side adjacent to angle $\hat{B}$" and "opposed to (or opposite) angle $\hat{C}$", while side b is the side adjacent to angle $\hat{C}$ and opposed to angle $\hat{B}$.



B
hypothenuse
a
opposite leg
c
A
b
adjacent leg
C

Figure 8.66: **Right triangle**

To say that the triangle is right at A means it is in $\hat{A}$ that is the right angle. Another quite common representation of a right triangle in college level textbook is:



C
H
θ
θ
A
B

Figure 8.67: **Another well known representation of right triangle**

Remark

In a right triangle, the longest side is always the side opposite the right angle. We will prove this property with the Pythagorean theorem (see further below).

8.2.3.3.5 Right Isosceles Triangle

Definition (#8.2.337): A "right isosceles triangle" ABC is both right and isosceles, meaning that it has both a right angle and two sides of equal length.

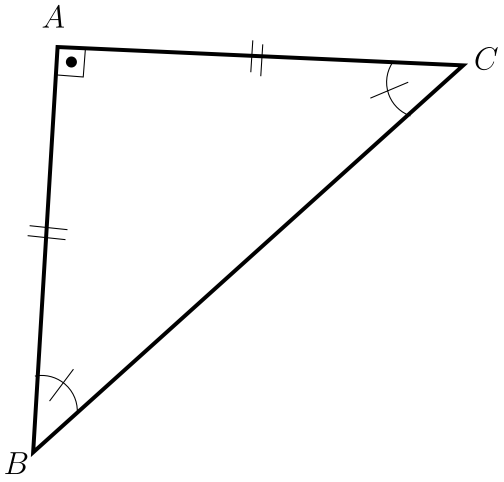


Figure 8.68: **Right isosceles triangle**

The main vertex (apex) corresponds to the right angle (A). Indeed, as $\overline{BC}$, the hypotenuse must be the greatest side, the sides $\overline{AB}$ and $\overline{AC}$ have the same length (smaller)!

So far we have for summary:

Based on sides	
Scalene triangle All three sides have different lengths. Its angles are also all different.	Isosceles triangle Two sides have equal lengths. Two of its angles are also equals	Equilateral (equiangular) triangle All three sides are of same length. All three angles are equal (60°)	Based on angles	
Acute triangle All angles are less than (90°)	Right triangle Has one right angle (90°)	Obtuse triangle Has one angle more than 90°	
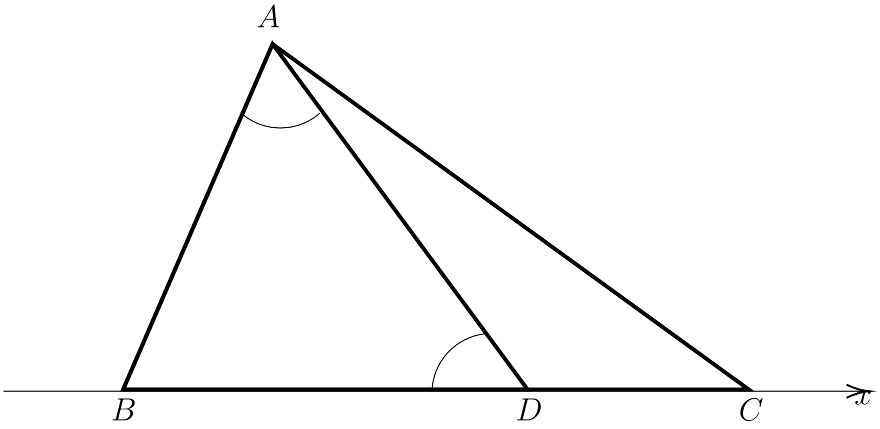
Figure 8.69: **Classification of plane triangles**

8.2.3.3.6 Inequalities in the triangles

Let us now see some interesting inequalities (properties) in the triangle.

P1. First let us prove that in any triangle, a side opposite to a right or obtuse angle (greater than 90° or $\pi/2$ [rad]) is greater than each of the other two sides of the triangle.

Proof 8.8.2. Consider the triangle ABC below where $\hat{A}\geq\pi/2$ and $\overline{Cx}$ the half-line extension of $\overline{BC}$. Let us draw, on the half-line Bx, a length $\overline{BD}=\overline{BA}$ to construct an isosceles triangle in the original triangle:



Therefore the triangle BAD is an isosceles triangle whose angle at the base AD is obviously acute (less than $\pi/2$ or less than 90°).

So by construction $\widehat{BAD}<\widehat{BAC}$. The straight line $\overline{AD}$ is interior by construction the angle $\widehat{BAC}$ and then it follows:

$$\overline{BC}>\overline{BD} \tag{8.2.52}$$

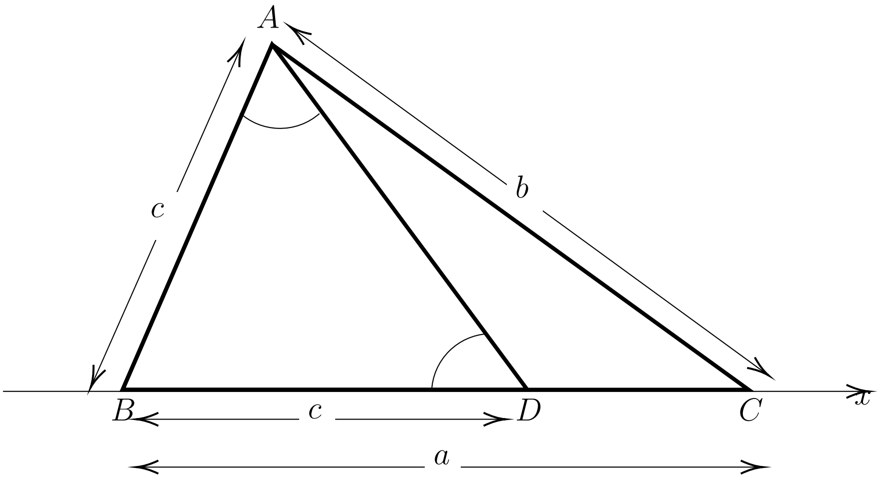
and as $\overline{BD}=\overline{BA}$ by construction we have:

$$\overline{BC}>\overline{BA} \tag{8.2.53}$$

Which finites our proof. As the reasoning is the same to prove that $\overline{BC}>\overline{CA}$.

■ Q.E.D.

P2. In any triangle whose sides have strictly increasing lengths, one side is always less than the sum of the other two.



Proof 8.8.3. Let D be the point of the side $\overline{BC}$ such that $\overline{BD}=\overline{BA}=c$ are the sides of the isosceles triangle ABD. We get:

$$\overline{DC}=\overline{BC}-\overline{BD}=a-c \tag{8.2.54}$$

The triangle ABD being isosceles, the angle at the base $\widehat{ADB}$ is acute and its complement $\widehat{ADC}$ is obtuse. In the ADC triangle, we get from the preceding equation P1 property $\overline{DC}<\overline{CA}$, that is to say:

$$a-c<b \tag{8.2.55}$$

where:

$$a<b+c \tag{8.2.56}$$

this is the famous "triangle inequality" in it geometrical version. We will see it again in many other sections of this textbook in spaces and more abstract mathematical concepts.

The property is the immediate for other sides b and c by permutation of the method:

$$\begin{gathered}a<b+c\\ b<a+c\\ c<a+b\end{gathered} \tag{8.2.57}$$

■ Q.E.D.

P3. In any triangle any side is greater than the difference of the other two.

Proof 8.8.4. Suppose we have $a>b>c$. Therefore we also have:

$$a+c>b \tag{8.2.58}$$

Subtracting c to both sides of the inequality gives:

$$a>b-c \tag{8.2.59}$$

The property is the immediate for the other sides b and c by permutation of the method:

$$a>b-c \tag{8.2.60}$$

$$b > a - c \tag{8.2.61}$$
$$c > a - b \tag{8.2.62}$$

And finally as:

$$a > b - c \quad \text{and} \quad a < b + c \tag{8.2.63}$$

for any triangle with increasing sides we have:

$$\boxed{b - c < a < b + c} \tag{8.2.64}$$

■ Q.E.D.

8.2.3.3.7 Triangles remarkable interior lines

A little summary about triangles remarkable interior lines is probably necessary at this point (before continuing on other triangles theorems) to avoid if possible to much confusion as we have given a lot of definitions so far:

- The "perpendicular bisector" of a segment is the line which is perpendicular to the segment and which passes through its center.
- The "height" or "altitude" of a triangle is a line which passes through a vertex of the triangle and which intercept the opposite edge with right angle.
- The "angle bisector" of an angle is the semi-straight line that divides the angle into two equal angles.
- The "median" of triangle passes through a vertex and intercepts the opposite edge at its center.
- The "mediator" is the perpendicular line to the crossing point of the median.

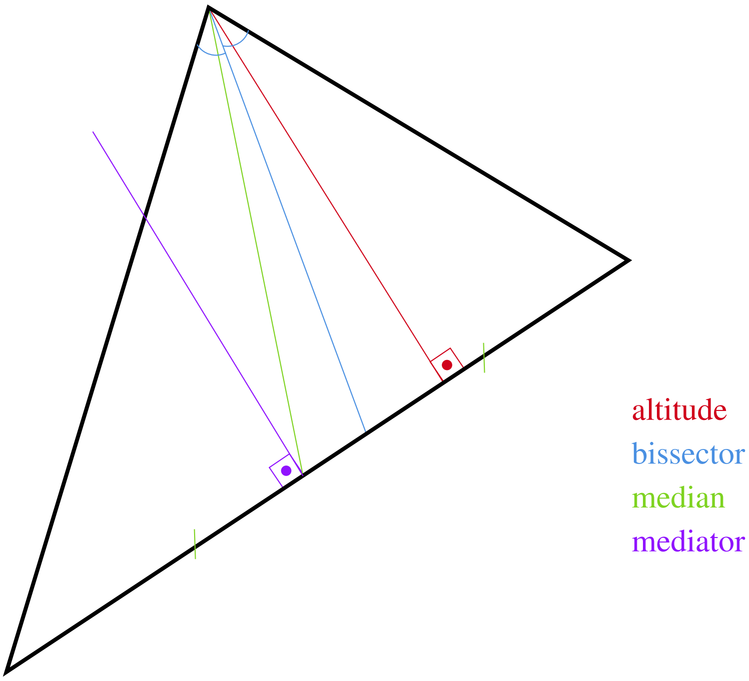


Figure 8.70: **Bisectors, Median, Mediator and Height in a triangle**

Obviously in some geometries all a part of all the lines above are not discernible.

In a triangle:

- The intersection of 3 altitudes is named the "orthocenter".
- The intersection of 3 medians is named the "centroid".
- The intersection of 3 angle bisectors is the "center of the inscribed circle".
- The intersection of 3 perpendicular bisectors is the center of the circumscribed circle.

8.2.3.3.8 Pythagorean theorem

Now that we have seen what was a triangle and reviewed some of its properties as well as the concept angle, we can prove the famous "Pythagorean theorem" that gives the relation that must satisfy three numbers that represent the sides of a right triangle in Euclidean Geometry and also permits to make circle trigonometry (see section Trigonometry page 2508).

Theorem 8.9. The square of the hypotenuse (the side opposite the right angle) is equal to the sum of the squares of the other two sides.

The theorem has been given numerous proofs - possibly the most for any mathematical theorem. They are very diverse, including both geometric proofs and algebraic proofs, with some dating back thousands of years. The theorem can be generalized in various ways, including higher-dimensional spaces, to spaces that are not Euclidean, to objects that are not right triangles, and indeed, to objects that are not triangles at all, but n-dimensional solids.

Among all possible proof we chose to present the next one as it seemed to most easy one to us for readers (student mainly in this case):

Proof 8.9.1. Given a square (four right angles polygon) inside which is inscribed another square of smaller sides. We can calculate the surface of the inscribed square thanks to the right triangles resulting from the empty spaces between the two squares such as presented below:

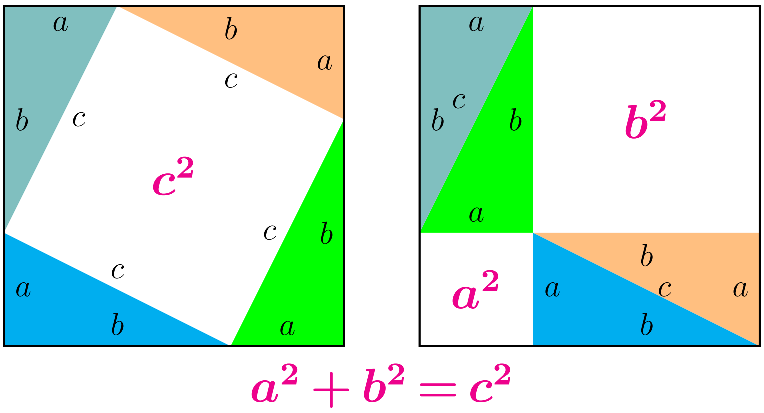

Figure 8.71: Pythagorean theorem illustrated

The surface of the whole square is obviously:

$$S=(a+b)^2=a^2+2ab+b^2 \tag{8.2.65}$$

and that of the white square:

$$S=c^2 \tag{8.2.66}$$

To get the surface of the white square we can subtract from the whole square the surface of the four right triangles having each for surface (see section Geometric Shapes page 2896):

$$S_\Delta=\frac{ab}{2} \tag{8.2.67}$$

The surface of the white square is finally:

$$(a+b)^2=a^2+2ab+b^2-4\frac{ab}{2}=a^2+b^2=c^2 \tag{8.2.68}$$

We then get the final result of the famous "Pythagorean theorem":

$$\boxed{a^2+b^2=c^2} \tag{8.2.69}$$

In a right triangle, the square of the hypotenuse (side opposite the right angle) is equal to the sum of the squares of sides of the right angle[3].

■ Q.E.D.

In the particular case we have three integers a, b and c that satisfy the Pythagorean theorem (there are infinite combinations of integers satisfying the Pythagorean theorem), then we speak of "Pythagorean triple".

Remark

We own this possible proof to the Chinese Chao King in the 102th century (holocene calendar).

It is often mentioned in smaller class of the reciprocal of Pythagorean theorem which states: In a triangle, if the square of one side is equal to the sum of the squares of the other two sides, then the triangle is rectangle and the hypotenuse will be the longest side of the triangle.

8.2.3.3.9 Thales' Theorem (intercept theorem)

The "intercept theorem", also known as "Thales' theorem" (not to be confused with another theorem with that name), is an important theorem in elementary geometry about the ratios of various line segments that are created if two intersecting lines are intercepted by a pair of parallels.

Having just proved the Pythagorean theorem and that now the concepts of parallels, segments, angles and others are quite well known to us, we can finally prove the Thales' theorem which is given here a possible proof that first requires the development of two lemmas:

Lemma 8.9.1. Triangles with same surfaces: If two triangles have a common side and if the third vertices are on a parallel to this common side, then they have the same surface!

Proof 8.9.2. Given the figure:

---

[3] Modern scholars seems to agree that Pythagoras of Samos never existed for real (as Homere, Adam, Eve, Moise, Noah, Jesus, etc.), that's why you won't found an entry about him in the section of Biographies. The Pythagorean theorem was also known and used by the Babylonians and Indians centuries before Pythagoras, but he may have been the first to introduce it to the Greeks

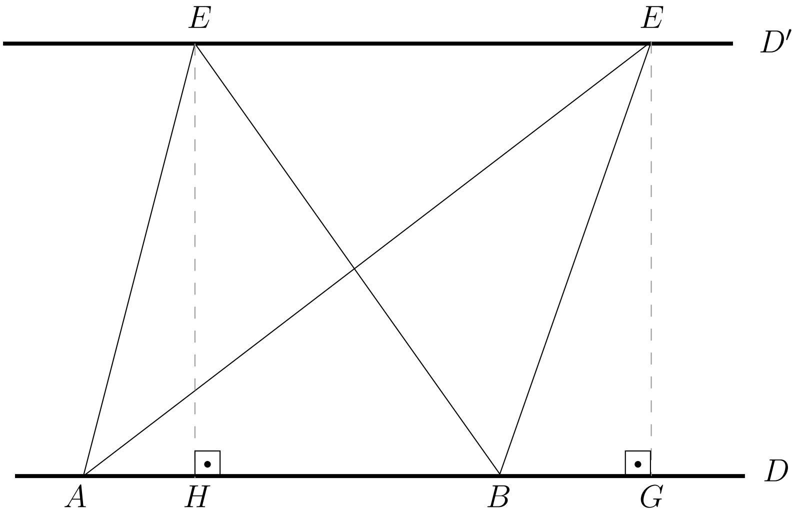

Figure 8.72: **First construction for Thales' theorem proof**

We have:

$$D//D' \quad (8.2.70)$$

$$\overline{EH} \perp D \quad (8.2.71)$$

$$\overline{FG} \perp D \quad (8.2.72)$$

$EFGH$ is a rectangle because its sides are parallel in pairs and have at least two right angles. So its opposite sides have the same length: $\overline{EH} = \overline{FG}$.

$\overline{EH}$ is the relative height to $\overline{AB}$ in the triangle EAB and $\overline{FG}$ is the relative height $\overline{AB}$ in the triangle FAB.

The surface of the triangle depends only on the length of the side and the length of the height relative this side (see section Geometric Shapes page 2896). For the both triangles EAB and FAB, these lengths are equal, so they have the same surface!

So we have indeed that if two triangles have a common side and if the third vertices are on a parallel to this common side, then they have the same surface!

■ Q.E.D.

Lemma 8.9.2. We have:

$$\frac{a+c}{b+d} = \frac{c}{d} \quad (8.2.73)$$

Proof 8.9.3. Given the proportions ratio ("proportional calculus" or "product in cross"):

$$\frac{a+c}{b+d} = \frac{c}{d} \quad (8.2.74)$$

then:

$$ad = bc \quad (8.2.75)$$

If $ad=bc$, then:

$$ad+cd=bc+cd \tag{8.2.76}$$

where we added a same positive or negative number to the two members of the equality. Thus after factorization:

$$d(a+c)=c(b+d) \tag{8.2.77}$$

and by applying contreversly the product in cross:

$$\boxed{\frac{a+c}{b+d}=\frac{c}{d}} \tag{8.2.78}$$

■ Q.E.D.

Let us now expose what is the Thales theorem.

Theorem 8.10. If two intersecting lines are cut by parallel lines, the line segments cut by the parallel lines from one of the lines are proportional to the corresponding line segments cut by them from the other line and from this we can also deduce also other remarkable identities.

Proof 8.10.1. Given the figure:

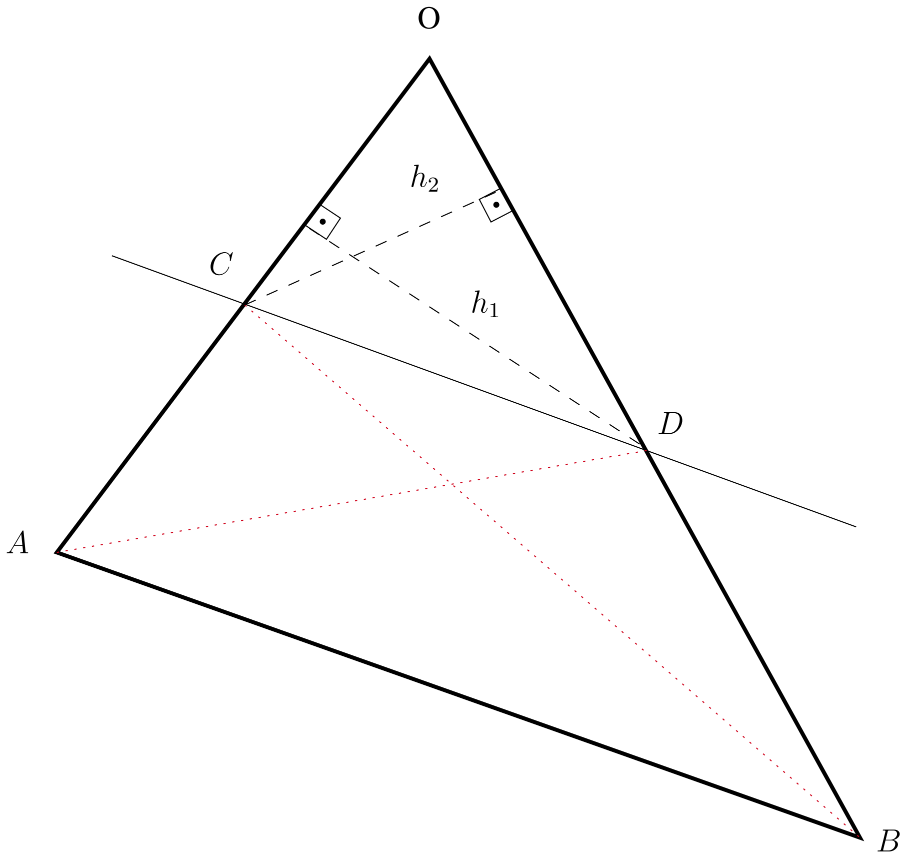

Figure 8.73: First approach of Thales' theorem

With:

$$\overline{AB}//CD \tag{8.2.79}$$

$$h_1 \perp \overline{\text{O}A} \tag{8.2.80}$$

$$h_2 \perp \overline{\text{O}B} \tag{8.2.81}$$

We have proven previously that if two triangles have a common side and if the third vertices are on a parallel, then they have the same surface. So the triangles ΔACD and ΔBCD have the same surface!

Adding to each of these two surfaces that of the triangle $\Delta \text{O}CD$, we get that the triangles $\Delta \text{O}DA$ and $\Delta \text{O}CB$ have the same surface!

We deduce then that using the product in cross that:

$$\frac{S_{\Delta \text{O}CD}}{S_{\Delta \text{O}AD}} = \frac{S_{\Delta \text{O}CD}}{S_{\Delta \text{O}CB}} \tag{8.2.82}$$

Given h_1 the height issue from D in the triangle $\Delta \text{O}CD$ and h_2 the height issue from C in the triangle $\Delta \text{O}CD$:

$$\frac{S_{\Delta \text{O}CD}}{S_{\Delta \text{O}AD}} = \frac{\overline{\text{O}C}\dfrac{h_1}{2}}{\overline{\text{O}A}\dfrac{h_1}{2}} = \frac{\overline{\text{O}C}}{\overline{\text{O}A}} \quad \text{and} \quad \frac{S_{\Delta \text{O}CD}}{\Delta S_{\text{O}CB}} = \frac{\overline{\text{O}D}\dfrac{h_2}{2}}{\overline{\text{O}B}\dfrac{h_2}{2}} = \frac{\overline{\text{O}D}}{\overline{\text{O}B}} \tag{8.2.83}$$

Conclusion:

$$\boxed{\frac{\overline{\text{O}C}}{\overline{\text{O}A}} = \frac{\overline{\text{O}D}}{\overline{\text{O}B}}} \tag{8.2.84}$$

Given now the figure:

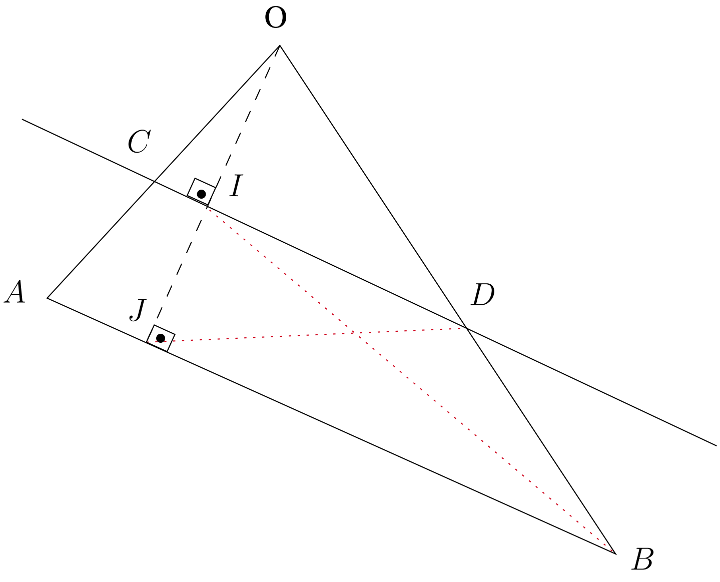

Figure 8.74: **Second approach of Thales' theorem**

The triangles ΔIJD and ΔIDB have the same surface from our first lemma, also same for the triangles $\Delta \text{O}JD$ and $\Delta \text{O}IB$ therefore:

$$S_{\Delta \text{O}JD} = \frac{1}{2}\overline{\text{O}J} \cdot \overline{DI} \qquad S_{\Delta \text{O}IB} = \frac{\overline{\text{O}J} \cdot \overline{JB}}{2} - \frac{\overline{JI} \cdot \overline{JB}}{2} = \frac{1}{2}\overline{\text{O}I} \cdot \overline{BJ} \tag{8.2.85}$$

hence:

$$\overline{\mathrm{O}J}\cdot\overline{DI}=\overline{\mathrm{O}I}\cdot\overline{BJ} \tag{8.2.86}$$

therefore:

$$\boxed{\frac{\overline{\mathrm{O}I}}{\overline{\mathrm{O}J}}=\frac{\overline{DI}}{\overline{BJ}}} \tag{8.2.87}$$

In the same way, in the triangles $\Delta \mathrm{O}IA$ and $\Delta \mathrm{O}CJ$, we get:

$$\frac{\overline{\mathrm{O}I}}{\overline{\mathrm{O}J}}=\frac{\overline{CI}}{\overline{AJ}} \tag{8.2.88}$$

From the second lemma as:

$$\boxed{\frac{\overline{\mathrm{O}I}}{\overline{\mathrm{O}J}}=\frac{\overline{DI}}{\overline{BJ}}=\frac{\overline{CI}}{\overline{AJ}}} \tag{8.2.89}$$

Then:

$$\frac{\overline{\mathrm{O}I}}{\overline{\mathrm{O}J}}=\frac{\overline{DI}}{\overline{BJ}}=\frac{\overline{CI}}{\overline{AJ}}=\frac{\overline{DI}+\overline{CI}}{\overline{BJ}+\overline{AJ}}=\frac{\overline{D}}{\overline{BA}} \tag{8.2.90}$$

By applying to the first triangle $\Delta \mathrm{O}JB$ what we did during the first approach, we also get:

$$\frac{\overline{\mathrm{O}I}}{\overline{\mathrm{O}J}}=\frac{\overline{\mathrm{O}D}}{\overline{\mathrm{O}B}} \tag{8.2.91}$$

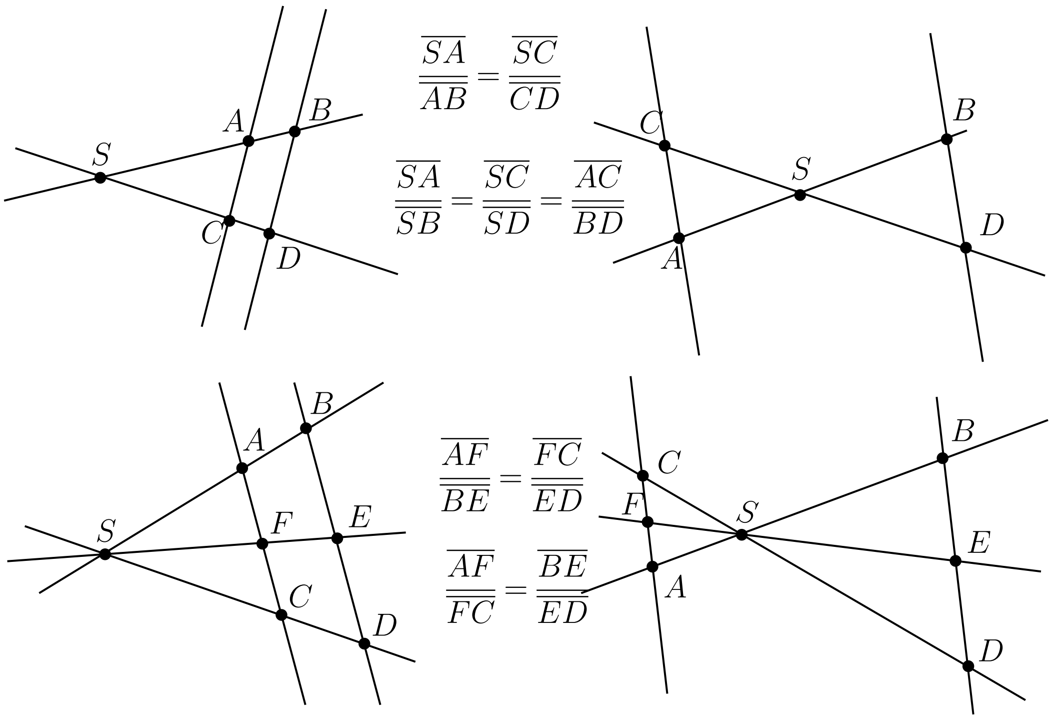
So finally by taking all previous results we get:

$$\boxed{\frac{\overline{\mathrm{O}I}}{\overline{\mathrm{O}J}}=\frac{\overline{DC}}{\overline{BA}}=\frac{\overline{\mathrm{O}D}}{\overline{\mathrm{O}B}}} \tag{8.2.92}$$

which constitutes the "Thales' theorem" of ratios.

■ Q.E.D.

Here is an excellent summary of what we have seen so far about Thales' theorem:



$\frac{\overline{SA}}{\overline{AB}}=\frac{\overline{SC}}{\overline{CD}}$
$\frac{\overline{SA}}{\overline{SB}}=\frac{\overline{SC}}{\overline{SD}}=\frac{\overline{AC}}{\overline{BD}}$
$\frac{\overline{AF}}{\overline{BE}}=\frac{\overline{FC}}{\overline{ED}}$
$\frac{\overline{AF}}{\overline{FC}}=\frac{\overline{BE}}{\overline{ED}}$

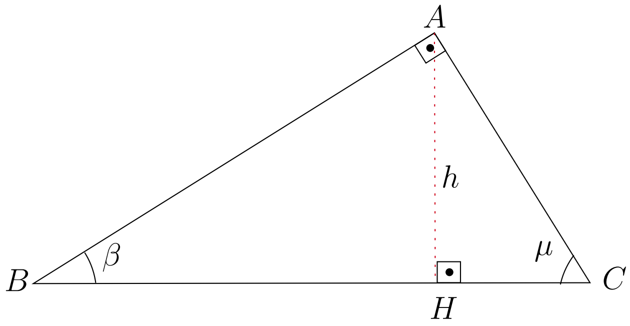
Figure 8.75: Thales' theorem (source: Wikipedia)

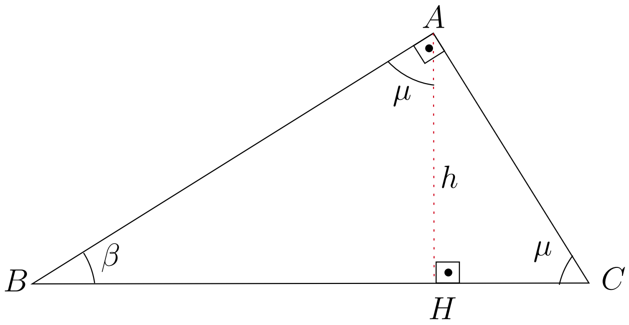
8.2.3.3.9.1 Euclid's (triangle) theorem

The Euclid's theorem uses Thales' theorem to give a relation in the below right angle triangle:

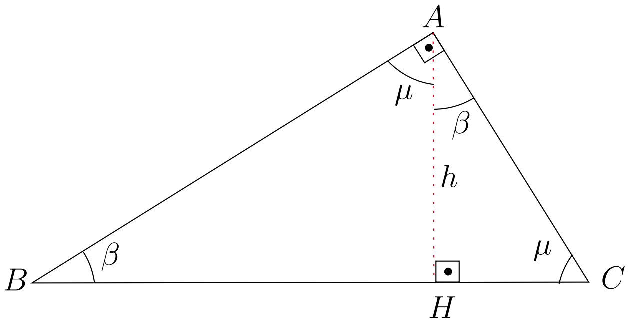


between h (i.e. $\overline{AH}$) and $\overline{BH}$ and $\overline{HC}$.

From the triangle above we see that $\beta+\mu=\pi/2$ as the sum of all angles of a triangle in the plane are equal to π. Therefore we can deduce that the angle μ is also here as the sum of the angles of ΔABH must also be equal to π:



Applying the same reasoning in the triangle ΔAHC we see also that the missing angle is by deduction obviously β itself:



Therefore the both triangles ΔABH and ΔAHC are similar and we can apply the Thales' theorem such that:

$$\frac{\overline{BH}}{\overline{AH}}=\frac{\overline{AH}}{\overline{HC}} \tag{8.2.93}$$

Rearranging we get:

$$\overline{AH}^2=\overline{BH}\cdot\overline{HC} \tag{8.2.94}$$

Or written differently:

$$\boxed{h^2=\overline{BH}\cdot\overline{HC}} \tag{8.2.95}$$

And that's the "Euclid's theorem" for right angle triangles in plane.

However, always in the same triangles we can write:

$$\frac{\overline{HC}}{\overline{AC}}=\frac{\overline{AC}}{\overline{BC}} \tag{8.2.96}$$

Therefore we get the second equality of Euclid's theorem for right triangles:

$$\overline{AC}^2=\overline{HC}\cdot\overline{BC} \tag{8.2.97}$$

And similarly we can get the third equality of Euclid's theorem:

$$\overline{AB}^2=\overline{HB}\cdot\overline{BC} \tag{8.2.98}$$

Remark

Sadly there are three theorems in mathematics named "Euclid's theorem" therefore that name is often quite confusing! Indeed, one of them is the theorem just seen above, the second one is a theorem of Euclid about the congruence of triangles (not presented in this textbook) and the third one is about prime numbers (also not presented in this textbook) but also named "Euclid's lemma" (see section Number Theory page 351).

8.2.3.4 Parallelism

Definition (#8.2.338): We name "parallels" two line (non-necessarily straight one!) equally distant from one another over their entire length.

This concept is directly connected to Euclid's fifth postulate (parallel postulate) and is often considered as the most important being been proved that it can not be considered as an axiom as it is not respected in non-Euclidean geometries (see section Non-Euclidean Geometry page 2663).

The consequences of this postulate are as we know the following in a Euclidean geometry:

1. If two lines AB and CD are parallels, any straight line $E'F'$ that cut one, cut the other one.

   Proof 8.10.2. Given F the common point to the straight line CD and the straight line $E'F'$: if the straight line $E'F'$ did not cut the straight line AB, it would be parallel to it, and through the point F would pass two straight lines CD and $E'F'$ parallel to a third one AB, which is not the case. So the straight line $E'F'$, cuts the line AB.

   ■ Q.E.D.

2. Two straight lines AB and CD parallels to a third line $E'F'$ are parallel between them.

   Proof 8.10.3. If the straight line CD was not parallel to the straight line AB it would cut (cross) it. It would also cut (cross) the straight line $E'F'$ parallel to the straight line AB, it would therefore not be parallel to $E'F'$.

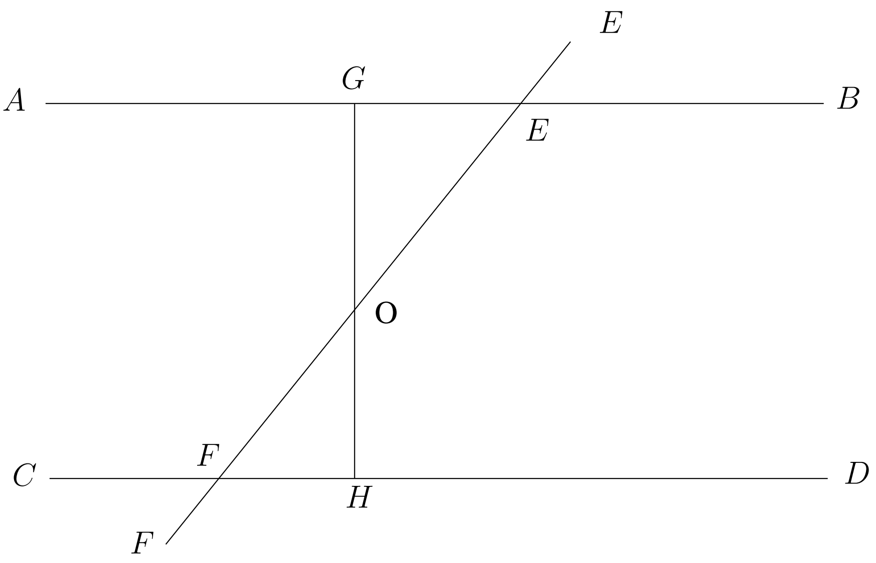
   ■ Q.E.D.

Theorem 8.11. If two parallels lines are cut by a secant then:

1. The intern-alternate angles are equal;
2. The external-alternate angles are equal;
3. The corresponding angles are equal.

If two lines are parallel then their alternate interior angles are equal. If the alternate interior angles of two lines are equal then the lines must be parallel. This is commonly named the "Z theorem".

Proof 8.11.1. Consider two (coplanar) parallel AB and CD and a secant EF:



1. By the middle O of EF let us conduct the perpendicular $\overline{GH}$ to AB, which is also perpendicular to CD. The right triangles $E\mathrm{O}G$ and $F\mathrm{O}H$ an acute angle equal to $\widehat{G\mathrm{O}E} = \widehat{F\mathrm{O}H}$ and an equal hypotenuse: $\mathrm{O}F = \mathrm{O}E$. They are equal, and the angles $\widehat{\mathrm{O}FH}$ and $\widehat{GE\mathrm{O}}$ are equal.

2. The alternate exterior angles $\widehat{E'EB}$ and $\widehat{F'FC}$ are equal, because $\widehat{E'EB}$ is opposed by the apex at the angle $\widehat{GE\mathrm{O}}$, which an intern-alternate with the angle $\widehat{\mathrm{O}FH}$.

■ Q.E.D.

... and vice versa if two straight lines are cut by a secant forming with these straight lines:

1. Two intern-alternate equal angles;
2. Two external-alternate equal angles;
3. Two corresponding equal angles.

then these two lines are parallel!

Remark

To prove the parallelism of two straight lines, it is necessary and sufficient that the intern-alternate angles, extern-alternate angles or corresponding angles, formed by these two straight lines with secant transversal, are all equal. That is to say equal to $\pi/2$.

8.2.3.5 Circle

Definition (#8.2.339): We name "circle" the locus of points M of the plane that are a given distance R, named "radius" of the circle, of a fixed point O, named "center of the circle". Or using the concept of "locus" defined earlier: a circle is defined as the locus of a point that is at a given distance of a fixed point, the center of the circle:

$$\overline{\mathrm{O}M}=R \tag{8.2.99}$$

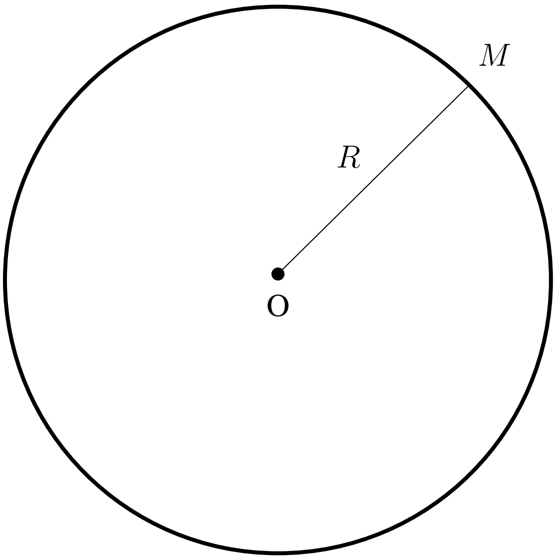


Figure 8.76: **Circle and Radius**

Remark

The word "radius" means either the segment $\overline{\mathrm{O}M}$, or its measurement R.

Circles are directly concerned by the third Euclid that we stated earlier above.

We name "diameter", denoted $\varnothing$, of a circle every line passing through the center O of the circle. Any diameter meets the circle at two points A and B, such that by construction:

$$\varnothing :=\overline{\mathrm{O}A}=\overline{\mathrm{O}B}=R \tag{8.2.100}$$

which we name "extremities of the diameter". We reserve the expression "diameter $\overline{AB}$" for the diameter of extremities A and B. We say that two points of a circle are "diametrically opposed" when they are the two ends of the same diameter:

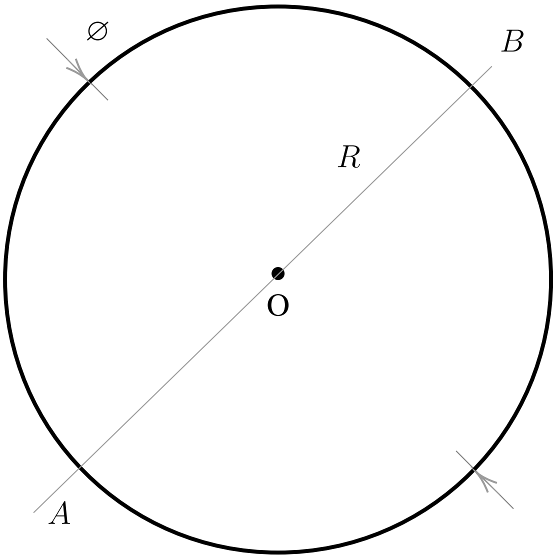

Figure 8.77: **Circle and Diameter**

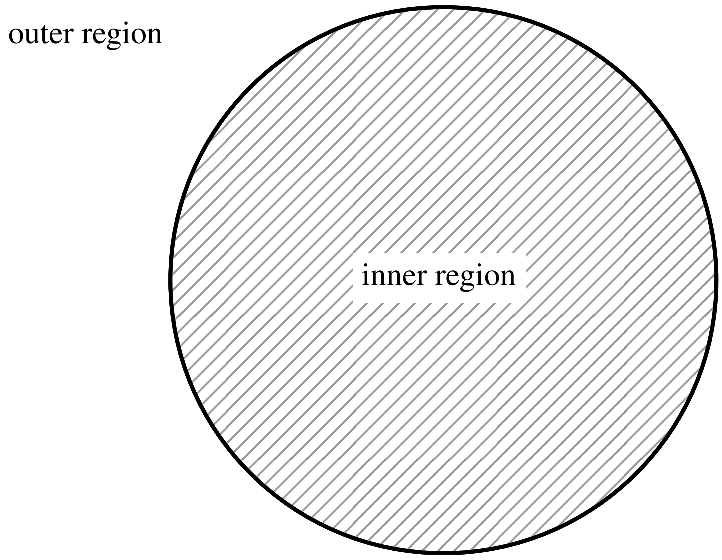
A circle divides the plane into two parts: one which contains the center, which we name "inner region" and one that does not contain it, which we name "outer region":



Theorem 8.12. The necessary and sufficient condition for a point P to be strictly inside a circle (C), of center O and radius R, is $\overline{OP} < R$.

Proof 8.12.1. There are two case to consider for the proof:

1. The condition is necessary: If, by hypothesis, P is inside the circle (C), it is located either on O, or between the ends A and B of the diameter defined by the locus of the points M. If it is on O the proposition is obvious, if it is not on O, then it is between O and A for example, and we have $\overline{\text{O}P} < \overline{\text{O}A}$, that is to say $\overline{OP} < R$.

2. The condition is sufficient: If, by hypothesis $\overline{OP} < R$, P is between the extremities A and B of the loci defined by the points M, so inside the circle (C).

■ Q.E.D.

Corollary 8.12.1. The necessary and sufficient condition for a point P to be outside a circle (C) is $\overline{\text{O}P} > R$.

We name "string of a circle" (C) the segment $\overline{CD}$ whose extremities C and D are on the circle (on the loci of M) as visible in the figure below.

Theorem 8.13. The mediator of a string $\overline{CD}$ is a diameter and obviously $C\text{O}D$ is an isosceles triangle.

Proof 8.13.1. The mediator Δ of $\overline{CD}$ (see figure below), string of the circle (C) of center O and radius R pass through the point O because as proved it during our study of the triangles we have $\overline{\text{O}R} = \overline{\text{O}D} = R$.

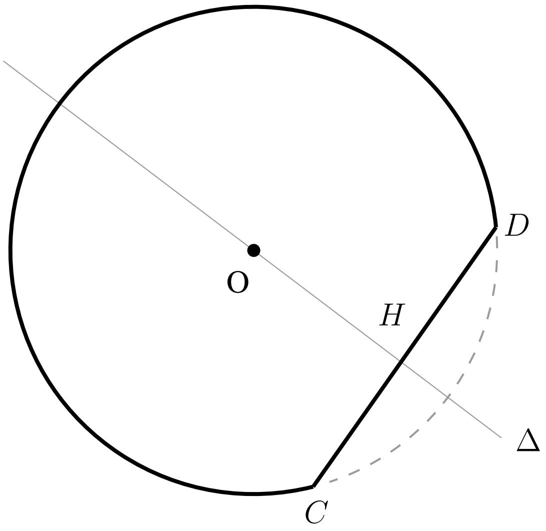


Figure 8.78: Mediator of circle string

■ Q.E.D.

Corollary 8.13.1. The perpendicular drawn from the center O of a circle of any circle string $\overline{CD}$ pass by construction through the middle H of this string.

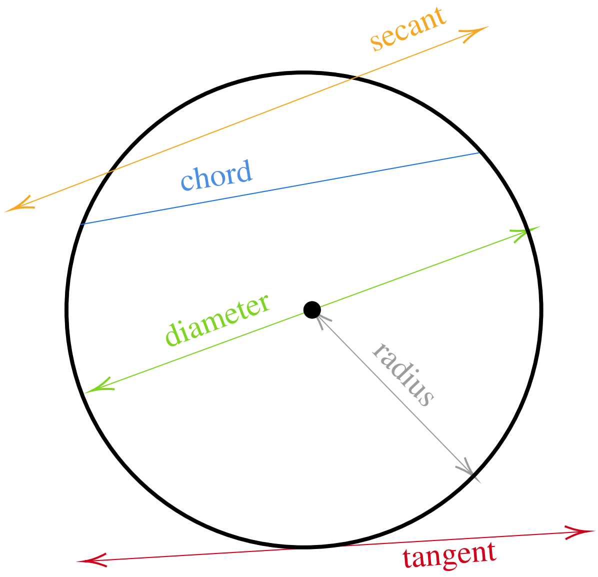

Figure 8.79: **Some common vocabulary for a circle**

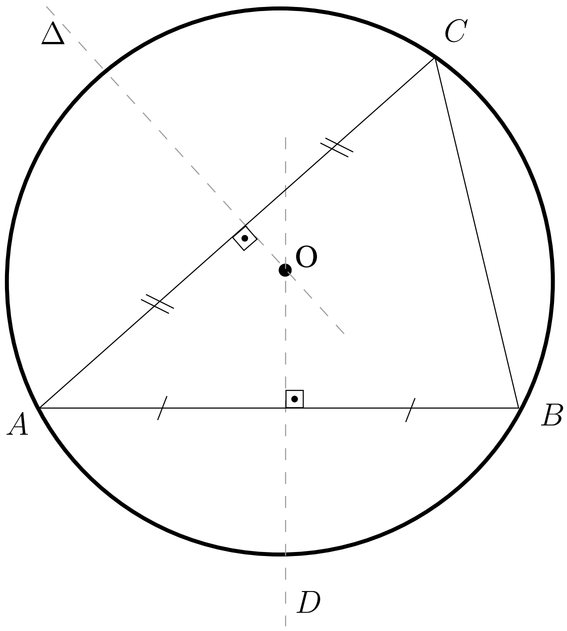
8.2.3.5.1 Circumscribed circle theorem

Theorem 8.14. By three points non-aligned A, B, C we can draw a circle and only one. This is the "circumscribed circle theorem".

Or in other words: All triangles are cyclic, i.e. every triangle has a circumscribed circle or "circumcircle".

Proof 8.14.1. First, we draw the mediator D of the segment $\overline{AB}$ and the mediator Δ of the segment $\overline{AC}$. If D and Δ were parallel, the perpendicular $\overline{AB}$ to D would be perpendicular also to Δ so coinciding with $\overline{AC}$. The points A, B, C would then be aligned. Therefore D and Δ are non-parallel and intersect at a point O:



1. There is one circle going through A, B, C:

   The point O being on D, mediator of $\overline{AB}$, $\overline{\mathrm{O}A}=\overline{\mathrm{O}B}$ by construction: the point O being on D, mediator of $\overline{AC}$, $\overline{\mathrm{O}A}=\overline{\mathrm{O}C}$. The circle (C), of center O and of radius $\overline{\mathrm{O}A}$ passes through B (since $\overline{\mathrm{O}A}=\overline{\mathrm{O}B}$) and also by C (since $\overline{\mathrm{O}A}=\overline{\mathrm{O}C}$). It therefore passes through A, B, C.

2. It goes through the points A, B, C only one circle:

   If it was going through A, B, C a different circle than that (C) of center O and radius $\overline{\mathrm{O}A}$, its center O' would be on the mediator of $\overline{AB}$ and $\overline{AC}$ that are two strings of the circle; it is then confused with O!

■ Q.E.D.

Remark

The mediator of $\overline{BC}$, string of the circle (C) above, also passes through the point O. We can say (important result!) that the three mediators of the sides of a triangle ABC are concurrent in a same point named the "orthocenter".

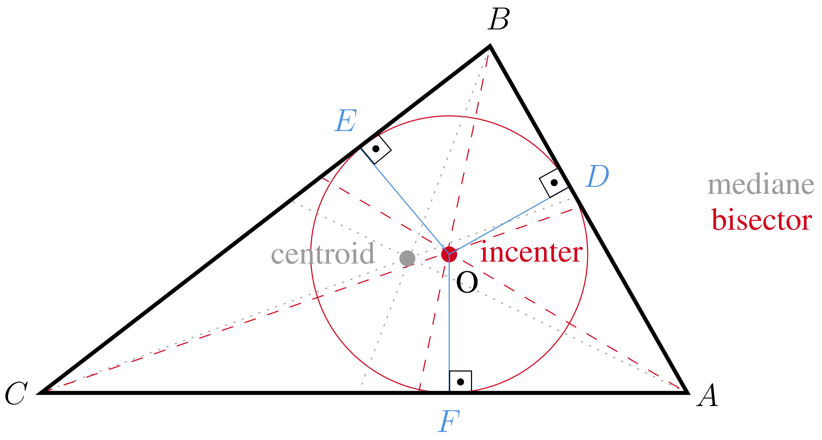
We will see further below that using the law of sines it's quite easy to get the diameter of the circumscribed circle and therefore its surface if we know its intern-angles. But if we don't know its intern-angles we need the center angles theorem that we will prove further below to calculate its surface.

8.2.3.5.2 Inscribed circle theorem

Theorem 8.15. It is the opposite of the previous theorem and states therefore a unique circle can be inscribed in any triangle, i.e. every triangle has an incircle tangent to it.

Proof 8.15.1. Given ABC, bisect the angles at the vertices A and B.

These angles bisectors must interact at a point O:



We locate afterwards the point D, E and F on sides $\overline{AB}$, $\overline{BC}$ and $\overline{CA}$ respectively so that:

$$\overline{\mathrm{O}D}\perp\overline{AB} \qquad \overline{\mathrm{O}E}\perp\overline{BC} \qquad \overline{\mathrm{O}F}\perp\overline{CA}$$

Observe that the triangles $\Delta A\mathrm{O}D$ and $\Delta A\mathrm{O}F$ are congruent and also the triangles $\Delta B\mathrm{O}D$ and $\Delta B\mathrm{O}E$ by the angle-side-angle theorem.

Since corresponding sides of congruent triangles are equal, we also know that:

$$\overline{\mathrm{O}D}=\overline{\mathrm{O}F} \quad \text{and } \overline{\mathrm{O}D}=\overline{\mathrm{O}E} \tag{8.2.101}$$

Hence:

$$R=\overline{\mathrm{O}D}=\overline{\mathrm{O}F}=\overline{\mathrm{O}E} \tag{8.2.102}$$

So the circle with center O and radius R is an incircle for the triangle.

■ Q.E.D.

We can be interested to calculate the surface of the incircle of radius R of the triangle ΔABC knowing only the distances between the points A, B and C.

So following the above figure, we consider the triangle ΔABC with incircle having center at O, we notice that:

$$S_{\Delta ABC}=S_{\Delta A\mathrm{O}B}+S_{\Delta B\mathrm{O}C}+S_{\Delta C\mathrm{O}A} \tag{8.2.103}$$

Thus:

$$S_{\Delta ABC}=\frac{1}{2}\overline{AB}R+\frac{1}{2}\overline{BC}R+\frac{1}{2}\overline{CA}R \tag{8.2.104}$$

That is:

$$S_{\Delta ABC}=\frac{R}{2}\left(\overline{AB}r+\overline{BC}r+\overline{CA}\right) \tag{8.2.105}$$

So:

$$S_{\Delta ABC}=\frac{R}{2}P_{\Delta ABC} \tag{8.2.106}$$

Therefore:

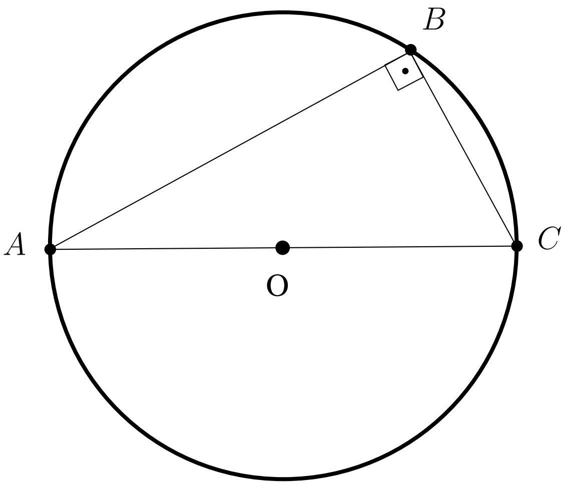
$$\boxed{R=\frac{2S_{\Delta ABC}}{P_{\Delta ABC}}} \tag{8.2.107}$$

where P is the perimeter of the triangle.

8.2.3.5.3 Thales' theorem of the circle

Theorem 8.16. If A, B and C are points on a circle where the segment $\overline{AC}$ is a diameter of the circle, then the angle $\widehat{ABC}$ is a right angle. This is the "Thales' theorem for circle".

Proof 8.16.1. Given the figure:



Since $\overline{\mathrm{O}A} = \overline{\mathrm{O}B} = \overline{\mathrm{O}C}$, the triangles $\Delta \mathrm{O}BA$ and $\Delta \mathrm{O}BC$ are therefore isosceles triangles, and by the equality of the base angles of an isosceles triangle, $\widehat{\mathrm{O}BC} = \widehat{\mathrm{O}CB}$ and $\widehat{BA\mathrm{O}} = \widehat{AB\mathrm{O}}$.

Let $\alpha = \widehat{BA\mathrm{O}}$ and $\beta = \widehat{\mathrm{O}BC}$. The three internal angles of the triangle ABC are α, $(\alpha+\beta)$, and β. Since the sum of the angles of a triangle is equal to π [rad] (180°), we have:

$$\begin{aligned} &\alpha + (\alpha+\beta) + \beta = \pi \\ &\Rightarrow 2\alpha + 2\beta = \pi \\ &\Rightarrow 2(\alpha+\beta) = \pi \\ &\therefore \alpha+\beta = \frac{\pi}{2} \end{aligned} \tag{8.2.108}$$

■ Q.E.D.

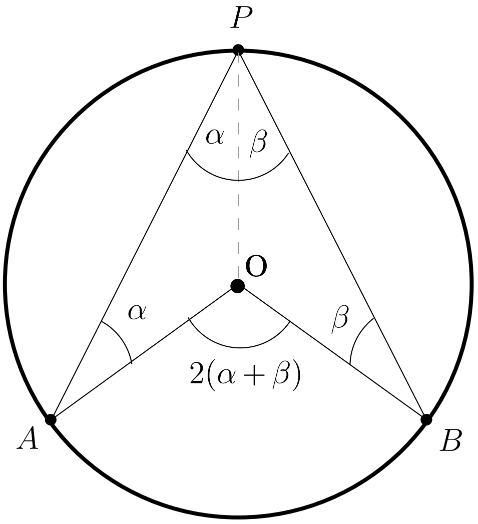
Corollary 8.16.1. If and only if the inscribed triangle is a right triangle, the circumcenter lies at the center of the hypotenuse.

8.2.3.5.4 Central angle theorem

The "central angle theorem" is very useful in solving questions that deals with angles within circles as we will see just after. The use of this theorem often simplifies a complicated situation into a rather simple one.

Theorem 8.17. The central angle theorem states that the central angle from two chosen points A and B on the circle is always twice the inscribed angle from those two points. The inscribed angle can be defined by any point P along the outer arc AB and the two points A and B.

Proof 8.17.1. Consider the following figure:



If we denote $\widehat{AP\text{O}}=\alpha$ and $\widehat{BP\text{O}}=\beta$ then it follows as $\Delta P\text{O}A$ and $\Delta P\text{O}B$ are isosceles triangle that:

$$\widehat{PA\text{O}}=\alpha \quad \text{and} \quad \widehat{PB\text{O}}=\beta \tag{8.2.109}$$

Using the fact that the sum of the angles of a triangle is equal to π (or $180°$) then:

$$\widehat{P\text{O}A}=\pi-2\alpha \tag{8.2.110}$$

$$\widehat{P\text{O}B}=\pi-2\beta \tag{8.2.111}$$

Since all angles at center O must add up to 2π (or $360°$), we have:

$$\widehat{A\text{O}B}=2\pi-(\pi-2\alpha)-(\pi-2\beta)=2\alpha+2\beta=2(\alpha+\beta) \tag{8.2.112}$$

Therefore:

$$\boxed{\widehat{A\text{O}B}=2\widehat{APB}} \tag{8.2.113}$$

Don't forget that this result is valid whatever the position of P on the circle!!!!!!

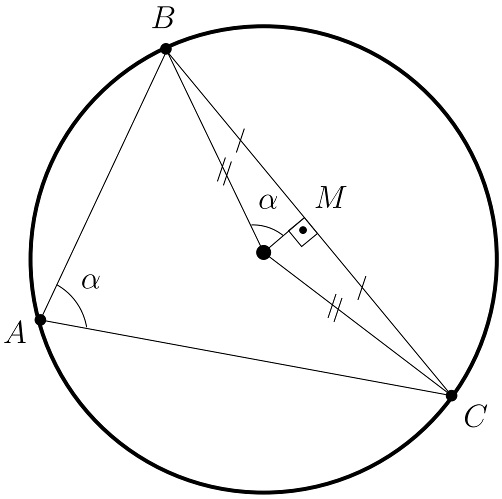
■ Q.E.D.

Using this theorem we can now prove that the relation that appears in the law of sines (see section Trigonometry page 2528) is the diameter of the circumcircle of the triangle ABC.

Theorem 8.18.

$$\varnothing=\frac{a}{\sin(\alpha)}=\frac{b}{\sin(\beta)}=\frac{c}{\sin(\gamma)} \tag{8.2.114}$$

Proof 8.18.1. For the proof consider the following figure:



Given the triangle ABC, let O denoted the center of its circumcircle.

Observe that $\widehat{BOC}=2\widehat{BAC}$ due to the central angle theorem.

That is:

$$\widehat{BOC}=2\alpha \tag{8.2.115}$$

Let M be the midpoint of $\overline{BC}$.

Then the triangle ΔBOM is congruent to the triangle ΔCOM by the side-side-side theorem.

So we have that:

$$\widehat{BOM}=\widehat{COM}=\frac{1}{2}\widehat{BOC} \tag{8.2.116}$$

since congruent angles in congruent triangles are equal.

By construction we have:

$$\widehat{OMB}=\widehat{OMC}=\frac{\pi}{2} \tag{8.2.117}$$

Let us now write:

$$\widehat{BOM}=\alpha \tag{8.2.118}$$

Now in the right triangle BOM we see that:

$$\sin(\alpha)=\frac{\overline{BM}}{\overline{BO}}=\frac{2\overline{BM}}{2\overline{BO}}=\frac{\overline{BM}+\overline{MC}}{2R}=\frac{\overline{BC}}{2R}=\frac{a}{\varnothing} \qquad (8.2.119)$$

Therefore:

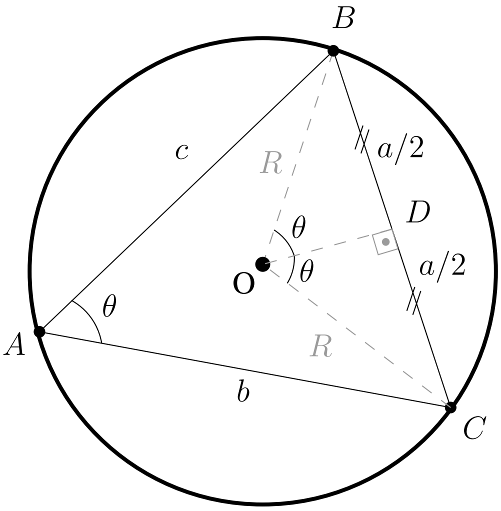
$$\varnothing=\frac{a}{\sin(\alpha)} \qquad (8.2.120)$$

Hence, by applying the law of sines, we conclude that:

$$\boxed{\varnothing=\frac{a}{\sin(\alpha)}=\frac{b}{\sin(\beta)}=\frac{c}{\sin(\gamma)}} \qquad (8.2.121)$$

■ Q.E.D.

So we can easily calculate the surface knowing the intern angles. But consider now that we don't know the intern-angles. So we also use the central angle theorem and the following figure:



From triangle $\Delta BD\text{O}$ we have:

$$\sin(\theta)=\frac{a/2}{R}=\frac{a}{2R} \qquad (8.2.122)$$

As we will prove in the section of Geometric Shapes, the surface of the internal triangle is:

$$S=\frac{1}{2}\text{basis}\cdot\text{height}=\frac{1}{2}b\cdot h \qquad (8.2.123)$$

So if we choose for basis of the triangle b and knowing that therefore:

$$\sin(\theta)=\frac{h}{c} \qquad (8.2.124)$$

we get:

$$S=\frac{1}{2}bc\sin(\theta)=\frac{1}{2}bc\left(\frac{a}{2R}\right)=\frac{abc}{4R} \qquad (8.2.125)$$

Therefore:

$$\boxed{R=\frac{abc}{4S_{\Delta ABC}}} \tag{8.2.126}$$

and we can then easily get the surface of the circumscribed circle from its radius.

8.2.4 Hilbert's Axioms

Euclid gathered all the geometric knowledge of his time in the form of the 5 postulates. He left his name to the Euclidean geometry that uses its fifth postulate, to non-Euclidean geometry that does not use it, and to Euclidean spaces.

This postulated base, however, is imperfect, to rigorously prove theorems associated with this geometry, it is necessary to accept as true additional implicit assumptions. David Hilbert built a corresponding axiomatic to the idea that made Euclid of the geometry by adding ad hoc assumptions (mathematicians make definitions with coffee...).

The Hilbert's axioms are grouped into five categories: the association, the order, the congruence, the continuity and the parallels.

Hilbert's axiom system is constructed with 6 primitive notions: three primitive terms and three primitive relations.

The three primitive terms are:

1. Point
2. Line
3. Plane

Remark

Points, lines and planes are considered a distinct by default.

The three primitive relations are:

1. That of association defines the word "contains" in geometry! It corresponds to the ideas "is part of" and "is included in" of Set Theory.
2. That of "order" is a binary relation between a couple of points and one point, it appears in the terms "between" and to define the segments.
3. That of "congruence", which corresponds to the three "equivalence relations" for the couples of points, the triangles and the angles.

Here are the "Hilbert's axioms":

8.2.4.1 Incidence Axioms (axioms of association)

A.A1. Given two points, there is a line going through these two points (contains them both).

A.A2. Given two points, there is one line and only one passing through these two points (verbatim the line described in A.A1).

A.A3. A line contains at least two points, and for a given line, there exists at least one point not contained into that line.

A.A4. Given three points that are not contained in a line, there is a plane containing the three points. Any plane contains at least one point.

A.A5. Given three points that are not contained in a line, there is only one plane containing the three points.

A.A6. Given two points contained in a line D and in a plane A, then A contains all the points of D.

A.A7. If two planes A and B both contain a point C, then the intersection of A and B contains at least one other point.

A.A8. There are at least four non coplanar points.

8.2.4.2 Order Axioms

A.O1. If point B is between the points A and C, B is then also between the points C and A, and there is a line containing the three points A, B, C.

A.O2. Given two points A and C, there is a point B element of the line $\overline{AC}$ such that C is between A and B.

A.O3. Given three points contained in a line, then a one and only is located between the other two.

A.O4. ("Pasch's theorem") Given three points A, B, C non-collinear, and given a line D in the plane ABC but containing none of the points A, B, C: If D contains a point of the segment $\overline{AB}$, then D contains either a point of the segment $\overline{AC}$ or a point of the segment $\overline{BC}$.

8.2.4.3 Congruence Axioms

First let us recall that intuitively "congruent" means in geometry "stackable" (exactly the same size and shape) at the opposite of "similar" (only one of the both properties are satisfied).

A.G1. Given two points A, B and a point A' element of a line d, there are two and two only unique points C and D, such that A' is between C and D, and $\overline{AB}$ is congruent to $\overline{A'C}$ and $\overline{AB}$ is congruent to $\overline{A'D}$.

A.G2. The congruence relation is transitive, that is to say, if $\overline{AB}$ is congruent to $\overline{CD}$ and if $\overline{CD}$ is congruent to $\overline{EF}$, then $\overline{AB}$ is congruent to $overlineEF$.

A.G3. Given a straight line d containing the adjacent segments $\overline{AB}$ and $\overline{BC}$, and given a straight line containing the adjacent segments $\overline{A'B'}$ and $\overline{B'C'}$. If $\overline{AB}$ is congruent to $\overline{A'B'}$ and $\overline{BC}$ is congruent to $\overline{B'C'}$ then $\overline{AC}$ is congruent to $\overline{A'C'}$.

A.G4. Given an angle $\widehat{ABC}$ and a half-line $\overline{B'C'}$, there are two and only two half-lines, $\overline{B'D}$ and $\overline{B'E}$, such that the angle $\widehat{DB'C'}$ is congruent to the angle $\widehat{ABC}$ and the angle $\widehat{EB'C'}$ is congruent to the angle $\widehat{ABC}$.

A.G5. Given two triangles ABC and $A'B'C'$ such that $\overline{AB}$ is congruent to $\overline{A'B'}$, $\overline{AC}$ is congruent to $\overline{A'C'}$, and the angle $\widehat{BAC}$ is congruent to the angle $\widehat{B'A'C'}$, then the triangle ABC is congruent to the triangle $A'B'C'$.

Therefore we see that these axioms are used to compare segments, and also angles, to define the center of a segment, the orthogonal lines, to talk about equilateral triangles, isosceles, etc. They also enable to strictly define the translations which was so often used by Euclid without having been defined.

8.2.4.4 Continuity Axioms

A.C1. Also named "Archimedes' axiom", this axiom assume that given two segments $\overline{AB}$ and $\overline{CD}$ then there is always a finite sequence of points $A_1,\ldots,A_n$ belonging to the line containing the segment $\overline{AB}$ and such that $A<A_1<\ldots<A_{n-1}<B<A_n$ that can satisfy $\overline{AA_1}\equiv\overline{AA_2}\equiv\ldots\overline{A_{n-1}A_n}\equiv\overline{CD}$.

A.C2. Also named "Cantor's Axiom" it assumes if (A_n) and (B_n) are two infinite sequence of points and that we build overlapping line segments $\overline{A_iB_i}$ such as $\overline{A_kB_k}\subset\overline{A_iB_i}$ if $i<k$ (also sometimes written $]A_{i+1},B_{i+1}[\subset]A_i,B_i[$) located on a line L and such that $\forall\overline{CD},\exists i:\overline{A_iB_i}\equiv\overline{CD}$, then there exists a point X belonging to all segments $\overline{A_iB_i}$. In other words: let there be a sequence of nested segments whose length tends towards 0 then there is a point common to all the segments.

It is not obvious but the Archimedean axiom is the result of the experience in a large number of measurements and guarantees the measurability of line segments. An arbitrary line segment can be attached a real number named the "line segment length". The axiom does not guarantee the inverse relation, that an arbitrary real number can be related to some line segment as the length of this line segment. This fact is guaranteed by the Cantor axiom.

8.2.4.5 Parallels Axioms

A.P1. Also known as the "Euclidean axiom" it assumes that given a straight line L and a point P not belonging to L, it passes one and only one straight line L' through P which is parallel to d.

Other equivalent formulation is:

A.P1'. Given a straight line L, a point P not included on L, then there exists a plane containing d and P. This plane contains one and only one straight line containing P and containing no point of d.

Any non-empty set of points (in the plane or in the space) consistent to the axiomatic system with the Euclidean postulate forms the Euclidean geometry (Euclidean plane $\mathcal{E}^2$, or Euclidean space $\mathcal{E}^3$) which is named also "parabolic geometry". One of the most well known theorems following directly from the Euclidean axiom of parallelism is that the sum of the interior angles in an arbitrary triangle equal π.

We can't really prove until now the non-contradictory logic of all these axioms. However, we know two things if we make an analogy with what we studied in the chapters Arithmetic and Algebra of this textbook (especially the section on Sets Theory, Functional Analysis and Sequences and Series):

1. If these axioms are contradictory, then the theory of real numbers is also contradictory.
2. If the system of axioms obtained by removing the axiom of Cantor is contradictory, then the theory of rational numbers is contradictory.

Thus, the confidence we have in the strength of these axioms lies on the one we have in the theory of real numbers, which is already also quite big.

8.2.5 Barycenter (centroid)

Now that we have discussed the minimum of the construction of Euclid and Hilbert geometry, we can move to a higher level to the analysis of properties of geometric shapes. We will begin by studying the concept of "center of gravity", also referred to but rarely to "centroid" or "barycenter" and that is very important not only in geometry but also in classical mechanics, astronomy and many other domains where multiple masses must be reduced to a single virtual point.

Remark

The definition of the barycenter requires some of the mathematical tools defined in the Vector Calculus section (see page 1794). Reading this section is therefore recommended if the reader wishes to understand what follows.

Definition (#8.2.340): We name "center of gravity" or "centroid" or "geometric center" of the points A_i of the plane or of the space affected respectively by the coefficients $\alpha_1, \alpha_2, \ldots, \alpha_n$ (where the α_i are real such that $\sum \alpha_i \neq 0$) the single point G (or also denoted sometimes CM for "Center of Mass") such that:

$$\boxed{\sum_{i=1}^{n} \alpha_i \overrightarrow{GA_i} = \vec{0}} \tag{8.2.127}$$

The couple denoted (A_i, α_i) is named "ponderated point" or "massive point" in the context of study of physics and when $\alpha_i > 0$ it represents the most often a mass. If all the α_i have the same value then the centroid is assimilated obviously to the mean position of all the points in all of the coordinate directions. Therefore a physical object has uniform density, then its center of mass is the same as the centroid of its shape!

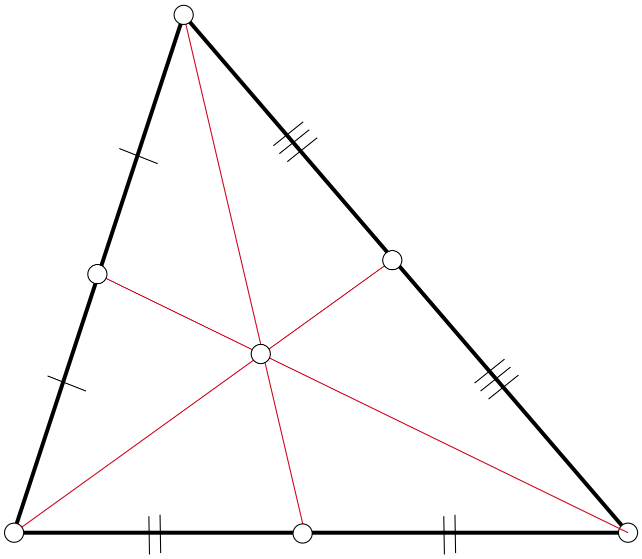


Figure 8.80: **Example of planar centroid (source: Wikpedia)**

Remarks

R1. In physics, the "center of inertia" of a body corresponds to the centroid of the particles that make up the body in question. Each particle being weighted by its own mass. So this is the point from which the mass is evenly distributed. If the density is constant, the center of mass coincides with the center of gravity as already mention.

R2. The "center of gravity" of a body corresponds to the centroid of the particles that make up the body in question, each particle being weighted by its own weight! Very often in mechanics, the size of the body is small compared with the roundness of the Earth, we consider a uniform gravity field. Under this assumption, the center of gravity and the center of mass coincide.

R3. When for any massive point (A_i,α_i) we have $\alpha_i=\alpha_j\;\forall(i,j)\in\mathbb{N}^*$, then we speak of "isobarycenter".

For an arbitrary point O, we obviously have by simple vector addition:

$$\sum_{i=1}^{n}\alpha_i\overrightarrow{GA_i}=\sum_{i=1}^{n}\alpha_i\left(\overrightarrow{\mathrm{O}A_i}-\overrightarrow{\mathrm{O}G}\right)=\sum_{i=1}^{n}\alpha_i\overrightarrow{\mathrm{O}A_i}-\left(\sum_{i=1}^{n}\alpha_i\right)\overrightarrow{\mathrm{O}G}=\vec{0} \tag{8.2.128}$$

hence the major result:

$$\boxed{\overrightarrow{\mathrm{O}G}=\frac{\displaystyle\sum_{i=1}^{n}\alpha_i\overrightarrow{\mathrm{O}A_i}}{\displaystyle\sum_{i=1}^{n}\alpha_i}} \tag{8.2.129}$$

Passing to the limit, if the domain is continuous (or can be considered as), we have:

$$\boxed{\overrightarrow{\mathrm{O}G}=\frac{\displaystyle\int\overrightarrow{\mathrm{O}M}\mathrm{d}l}{\displaystyle\int\mathrm{d}l}=\frac{\displaystyle\int\overrightarrow{\mathrm{O}M}\mathrm{d}l}{L}} \tag{8.2.130}$$

We may well also work with the surface or volumes elements (to mention only the more trivial case) to determine the centroid:

$$\overrightarrow{\mathrm{O}G}=\frac{\displaystyle\iint\overrightarrow{\mathrm{O}M}\mathrm{d}S}{\displaystyle\iint\mathrm{d}S}=\frac{\displaystyle\iint\overrightarrow{\mathrm{O}M}\mathrm{d}S}{S}\qquad\text{and}\qquad\overrightarrow{\mathrm{O}G}=\frac{\displaystyle\iiint\overrightarrow{\mathrm{O}M}\mathrm{d}V}{\displaystyle\iiint\mathrm{d}V}=\frac{\displaystyle\iiint\overrightarrow{\mathrm{O}M}\mathrm{d}V}{V} \tag{8.2.131}$$

✍**Example:**

To calculate for example the centroid of the area between the $0x$ axis and the parabola function $y=kx^2$ for $0\leq x\leq a$ we have (do not forget that when we calculate the centroid along the y axis that we have to take it the right side of the curve!):

$$\overrightarrow{\mathrm{OG}}=\begin{pmatrix}G_x\\G_y\end{pmatrix}=\begin{pmatrix}\dfrac{\iint x\mathrm{d}S}{\iint \mathrm{d}S}\\\dfrac{\iint xy\mathrm{d}S}{\iint \mathrm{d}S}\end{pmatrix}=\begin{pmatrix}\dfrac{\iint x\mathrm{d}S}{\iint \mathrm{d}S}\\\dfrac{\iint xkx^2\mathrm{d}S}{\iint \mathrm{d}S}\end{pmatrix} \tag{8.2.132}$$

in the first component we have $\mathrm{d}S=y\mathrm{d}x$ so the double integral becomes a simple integral!

For the second component we can't use $\mathrm{d}S=x\mathrm{d}y$ as it represent an element of area between the y-axis and the parabola curve. Indeed, we want the outside area (above the parabola curve when see of the point of view of the y-axis!). Therefore the idea is to translate the parabola of a so that the parabola surface relatively to y will be the expected one. Therefore we have $\mathrm{d}S=(x-a)\mathrm{d}y$.

And it comes:

$$\begin{aligned}\overrightarrow{\mathrm{OG}}&=\begin{pmatrix}\dfrac{\iint x\mathrm{d}S}{\iint \mathrm{d}S}\\\dfrac{\iint xkx^2\mathrm{d}S}{\iint \mathrm{d}S}\end{pmatrix}=\begin{pmatrix}\dfrac{\int\limits_0^a xy\mathrm{d}x}{\int\limits_0^a y\mathrm{d}x}\\\dfrac{\int\limits_0^b kx^2(x-a)\mathrm{d}y}{\int\limits_0^b (x-a)\mathrm{d}y}\end{pmatrix}=\begin{pmatrix}\dfrac{\int\limits_0^a xkx^2\mathrm{d}x}{\int\limits_0^a kx^2\mathrm{d}x}\\\dfrac{\int\limits_0^a kx^2(x-a)2kx\mathrm{d}x}{\int\limits_0^a (x-a)2kx\mathrm{d}x}\end{pmatrix}\\&=\begin{pmatrix}\dfrac{\int\limits_0^a x^3\mathrm{d}x}{\int\limits_0^a x^2\mathrm{d}x}\\k\dfrac{\int\limits_0^a x^3(x-a)\mathrm{d}x}{\int\limits_0^a x(x-a)\mathrm{d}x}\end{pmatrix}=\begin{pmatrix}\dfrac{\left.\frac{1}{4}x^4\right|_0^a}{\left.\frac{1}{3}x^3\right|_0^a}\\\dfrac{\left.\frac{1}{5}x^5-\frac{1}{4}ax^4\right|_0^a}{\left.\frac{1}{3}x^3-\frac{1}{2}ax^2\right|_0^a}\end{pmatrix}=\begin{pmatrix}\dfrac{3}{4}\dfrac{a^4}{a^3}\\k\dfrac{\frac{1}{5}a^5-\frac{1}{4}a^5}{\frac{1}{3}a^3-\frac{1}{2}a^3}\end{pmatrix}=\begin{pmatrix}\dfrac{3}{4}a\\k\dfrac{-\frac{1}{20}a^5}{-\frac{1}{6}a^3}\end{pmatrix}\\&=\begin{pmatrix}\dfrac{3}{4}a\\k\dfrac{3}{10}a^2\end{pmatrix}\end{aligned} \tag{8.2.133}$$

Remark

When we calculate the center of gravity of a function as in the example above, then we speak of "weighted curve".

In space with a reference frame $(\mathrm{O},\vec{i},\vec{j},\vec{k})$ by writing (x_i,y_i,z_i) the coordinates of the weighted points (A_i,α_i) and (x_G,y_G,z_G) those of G, then we have (in the discrete case):

$$\boxed{x_G=\frac{\displaystyle\sum_{i=1}^{n}\alpha_i x_i}{\displaystyle\sum_{i=1}^{n}\alpha_i}\qquad y_G=\frac{\displaystyle\sum_{i=1}^{n}\alpha_i y_i}{\displaystyle\sum_{i=1}^{n}\alpha_i}\qquad z_G=\frac{\displaystyle\sum_{i=1}^{n}\alpha_i z_i}{\displaystyle\sum_{i=1}^{n}\alpha_i}}\tag{8.2.134}$$

Let us now give and prove some properties of the centroid (center of mass/gravity):

P1. Given $(A_1,\alpha_1),(A_2,\alpha_2),\ldots,(A_n,\alpha_n)$, n weighted points. If $\sum\alpha_i\neq 0$, we have then for any point M:

$$\sum_{i=1}^{n}\alpha_i\overrightarrow{MA_i}=\left(\sum_{i=1}^{n}\alpha_i\right)\overrightarrow{MA_i}\tag{8.2.135}$$

Proof 8.18.2.

$$\begin{aligned}\sum_{i=1}^{n}\alpha_i\overrightarrow{MA_i}&=\alpha_1\overrightarrow{MA_1}+\alpha_2\overrightarrow{MA_2}+\ldots+\alpha_n\overrightarrow{MA_n}\\&=\alpha_1\left(\overrightarrow{MG}+\overrightarrow{GA_1}\right)+\alpha_2\left(\overrightarrow{MG}+\overrightarrow{GA_2}\right)+\ldots+\alpha_n\left(\overrightarrow{MG}+\overrightarrow{GA_n}\right)\\&=(\alpha_1+\alpha_2+\ldots+\alpha_n)\overrightarrow{MG}+\alpha_1\overrightarrow{GA_1}+\alpha_2\overrightarrow{GA_2}+\ldots+\alpha_n\overrightarrow{GA_n}\\&=\left(\sum_{i=1}^{n}\alpha_i\right)\overrightarrow{MG}+\sum_{i=1}^{n}\alpha\overrightarrow{GA_i}\end{aligned}\tag{8.2.136}$$

As by definition of the barycenter we have:

$$\sum_{i=1}^{n}\alpha_i\overrightarrow{GA_i}=\vec{0}\tag{8.2.137}$$

Then we have indeed:

$$\sum_{i=1}^{n}\alpha_i\overrightarrow{MA_i}=\left(\sum_{i=1}^{n}\alpha_i\right)\overrightarrow{MG}+\sum_{i=1}^{n}\alpha_i\overrightarrow{GA_i}=\left(\sum_{i=1}^{n}\alpha_i\right)\overrightarrow{MG}\tag{8.2.138}$$

■ Q.E.D.

P2. For $\forall k\in\mathbb{R}^*$, the weighted points $(A_1,\alpha_1),(A_2,\alpha_2),\ldots,(A_n,\alpha_n)$ and $(A_1,k\alpha_1),(A_2,k\alpha_2),\ldots,(A_n,k\alpha_n)$ have same barycenter because (invariance of the barycenter):

$$\sum_{i=1}^{n}\alpha_i\overrightarrow{GA_i}=\vec{0}\Leftrightarrow\sum_{i=1}^{n}(k\alpha_i)\overrightarrow{GA_i}=\vec{0}\tag{8.2.139}$$

Proof 8.18.3. The proof is in our point of view immediate (but if you don't see it don't hesitate as always to contact us and we will write it).

■ Q.E.D.

P3. The barycenter G of n weighted points is invariant when we replace p of them, by their barycenter G', assigned to the condition that their coefficients are such that $\sum_{i=1}^{n}\alpha_i \neq 0$, then G is the barycenter of:

$$\left(G'_i, \sum_{i=1}^{p}\alpha_i\right), (A_{p+1}, \alpha_{p+1}), \ldots, (A_n, \alpha_n) \tag{8.2.140}$$

Proof 8.18.4. If G' is the barycenter of the weighted points $(A_1, \alpha_1), (A_2, \alpha_2), \ldots, (A_p, \alpha_p)$ then:

$$\sum_{i=1}^{p}\alpha_i\overrightarrow{MA_i} = \left(\sum_{i=1}^{p}\alpha_i\right)\overrightarrow{MG'} \tag{8.2.141}$$

For the particular case where $M = G$:

$$\sum_{i=1}^{p}\alpha_i\overrightarrow{GA_i} = \left(\sum_{i=1}^{p}\alpha_i\right)\overrightarrow{GG'} \tag{8.2.142}$$

But G being the barycenter of the n weighted points $(A_1, \alpha_1), (A_2, \alpha_2), \ldots, (A_n, \alpha_n)$ we have then:

$$\sum_{i=1}^{n}\alpha_i\overrightarrow{GA_i} = \vec{0} \Leftrightarrow \sum_{i=1}^{p}\alpha_i\overrightarrow{GA_i} + \sum_{i=p+1}^{n}\alpha_i\overrightarrow{GA_i} = \left(\sum_{i=1}^{p}\alpha_i\right)\overrightarrow{GG'} + \sum_{i=p+1}^{n}\alpha_i\overrightarrow{GA_i} = \vec{0} \tag{8.2.143}$$

As:

$$\sum_{i=1}^{p}\alpha_i + \sum_{i=p+1}^{n}\alpha_i \neq 0 \tag{8.2.144}$$

the previous equality proves that G is the barycenter of weighted points:

$$\left(G'_i, \sum_{i=1}^{p}\alpha_i\right), (A_{p+1}, \alpha_{p+1}), \ldots, (A_n, \alpha_n) \tag{8.2.145}$$

■ Q.E.D.

P4. If $\sum\alpha_i = 0$, for any point M, N:

$$\sum_{i=1}^{n}\alpha_i\overrightarrow{MA_i} = \sum_{i=1}^{n}\alpha_i\overrightarrow{NA_i} = c^{te} \tag{8.2.146}$$

Proof 8.18.5. For $M \neq N$ let us calculate:

$$\begin{aligned}
&\sum_{i=1}^{n}\alpha_i\overrightarrow{MA_i}-\sum_{i=1}^{n}\alpha_i\overrightarrow{NA_i}\\
&=\alpha_1\overrightarrow{MA_1}+\alpha_2\overrightarrow{MA_2}+\ldots+\alpha_n\overrightarrow{MA_n}-\alpha_1\overrightarrow{NA_1}-\alpha_2\overrightarrow{NA_2}-\alpha_2\overrightarrow{NA_2}-\ldots-\alpha_n\overrightarrow{NA_n}\\
&=\alpha_1\left(\overrightarrow{MA_1}-\overrightarrow{NA_1}\right)+\alpha_2\left(\overrightarrow{MA_2}-\overrightarrow{NA_2}\right)+\ldots+\alpha_n\left(\overrightarrow{MA_n}-\overrightarrow{NA_n}\right)\\
&=\alpha_1\overrightarrow{MN}+\alpha_2\overrightarrow{MN}+\ldots+\alpha_n\overrightarrow{MN}\\
&=(\alpha_1+\alpha_2+\ldots+\alpha)\overrightarrow{MN}=\left(\sum_{i=1}^{n}\alpha_i\right)\overrightarrow{MN}=\vec{0}
\end{aligned} \tag{8.2.147}$$

as $\sum_{i=1}^{n}\alpha_i=0$, we then have:

$$\sum_{i=1}^{n}\alpha_i\overrightarrow{MA_i}=\sum_{i=1}^{n}\alpha_i\overrightarrow{NA_i}=c^{te} \tag{8.2.148}$$

■ Q.E.D.

Remark

When a body has a certain symmetry, the calculations are simplified because the center of gravity (barycenter) should coincide with the element of symmetry. If a body such as a sphere, parallelepiped, etc., has a center of symmetry, the centroid is coincides with it. If the body only has one axis of symmetry, the centroid is then on this axis.

8.2.6 Geometric Transformations

The transformations in the plane (and spaces of more dimensions) are usually strictly defined using group theory (see section Set Algebra page 1417). But in the context of Euclidean geometry, this Set Theory approach does not interest us. So we will do in this subsection only a simple formal approach (and therefore more intuitive) of elementary transformations in the plane that are: translation, scaling, rotation and skew (shear). For the translation we will see also the equivalent in space as it is very important for our study of Physics (especially for the study of the gyroscope).

Remark

By definition an "isometry" is a transformation that preserves distances and areas (distance-preserving injective map between metric spaces). As we will see below, the translation, rotation and reflection are isometries. The scaling being obviously not an isometry in the plane or the space.

Figure 8.81: **Most common type of geometric transformations**

8.2.6.1 Translation

Given a straight line in a plane P on which two points A and B define a segment of line denoted $\overline{AB}$.

Definition (#8.2.341): A "translation T" ("displacement in a given direction" as said Euclid) of this line segment associates with each point A and B new points A' and B' such that $\overline{AB}=\overline{A'B'}$. So we can restrict the notion of translation to a point only if we want such that mathematically we can write:

$$T:P\rightarrow P\Rightarrow T(A)=A' \tag{8.2.149}$$

In other words, a transformation function (application) of the type transformation T of the of the entire plane in itself associates with each pre-image not more than a single image. Translation is therefore a bijective function. So we can define a unique reciprocal transformation application denoted as T^{-1} (recall of what was seen in the chapter Arithmetics):

$$T^{-1}(A')=A \tag{8.2.150}$$

We say by definition a point is "translationally invariant" if and only if:

$$T(A)=A'=A \tag{8.2.151}$$

In another type of formalism, the displacement of the point A to point B following the vector $\overrightarrow{AB}$ is named "translation vector $\overrightarrow{AB}$" equation (see section Vector Calculus page 1815). It is expressed mathematically by the sum of the point coordinates and the matrix of the coordinates of the vector (see just below the details).

For example in a three-dimensional space:

$$(x,y,z)+(x',y',z')=(x+x',y+y',z+z') \tag{8.2.152}$$

The translation is not a linear transformation (see section Linear Algebra page 1934), we can not allow ourselves to be represented by the multiplication of a square matrix as we will see it for following other transformations (scaling and transformation).

For this purpose (be able to express this transformation as square matrix linear application) we must use a workaround consisting in using a system named "homogeneous coordinates" (see section Projective Geometry page 2759) where the points of the plane are represented by a vector having 3 components (and respectively those of space by a vector with 4 components):

$$\begin{pmatrix}x\\y\end{pmatrix}\Rightarrow\begin{pmatrix}x_h\\y_h\\w\end{pmatrix}\qquad\text{with:}\qquad\begin{aligned}x_h&=x\cdot w\\y_h&=x\cdot w\end{aligned} \tag{8.2.153}$$

In the context of the study of translation we put $w=1$ because in this case:

$$\boxed{\begin{pmatrix}x'\\y'\\1\end{pmatrix}=\begin{bmatrix}1&0&T_x\\0&1&T_y\\0&0&1\end{bmatrix}\begin{pmatrix}x\\y\\1\end{pmatrix}=\begin{pmatrix}1\cdot x+0\cdot y+T_x\cdot 1\\0\cdot x+1\cdot y+T_y\cdot 1\\0+0+1\cdot 1\end{pmatrix}=\begin{pmatrix}x+T_x\\y+T_y\\1\end{pmatrix}} \tag{8.2.154}$$

This system of homogeneous coordinates is applicable to all other transformation we will see later by adding each time a coordinate (see section Projective Geometry page 2759).

Remark

Translation sends a line on a parallel line to the original line of course!

8.2.6.2 Homothety (scaling)

Given any shape in the plane or space (point, line, oval, polygon, etc.), a number R, and a point placed C at a predefined location.

Definition (#8.2.342): A "homothetic transformation H" (also named "scaling" or rarely "enlargement") of ratio R and center C is the application that at every point M of the shape associates to the segment $\overline{CM}$ a new point collinear to $\overline{CM}$ but arranged at a greater or smaller distance of ratio R from the center C such that $\overline{CM'} = R \cdot \overline{CM}$.

We can restrict the concept of scaling to a line segment such that we can write mathematically:

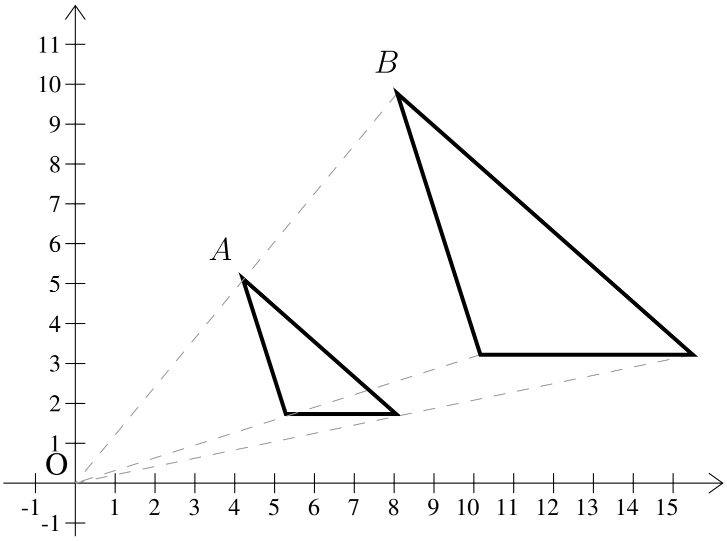
$$H : P \to P \Rightarrow H(\overline{CM}) = R \cdot \overline{CM} = \overline{CM'} \qquad (8.2.155)$$

In other words, a transformation of the type scaling in the entire plan in itself associates with each pre-image not more than a single image. Dilation is therefore as for the translation a bijective function. We can the define a reciprocal transformation application denoted H^{-1} such that as:

$$H^{-1}(R \cdot \overline{CM}) = \overline{CM} \qquad (8.2.156)$$

If $R \neq 1$, then C is the only invariant point. If $R = 1$, then all points are invariant and the scaling is say to be of the type "scaling identity". If $R = -1$, then we say that we have a "central symmetry". A central symmetry is then a rotation of $180°$ (or π [rad]).

In another type of formalism, a scaling of center O and ratio k, associate to the point A a point B such that $\overline{\text{O}B} = k\overline{\text{O}A}$. The point B being located on the straight line OA and at a distance $\overline{\text{O}B} = k\overline{\text{O}A}$. The sign of k determines the position of B with respect to O:



$$\overline{\text{O}B} = k\overline{\text{O}B} \Leftrightarrow (x', y', z') = k(x, y, z)$$

Figure 8.82: **Example of scaling of center O**

We now make a jump in the spatial geometry (the jump is not very large and require just the knowledge of elementary vector calculus and linear algebra).

We can also replace the scalar k by a square matrix such that:

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \begin{pmatrix} a & b & c \\ d & e & f \\ g & h & i \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} ax+by+cz \\ dx+ey+fz \\ gx+hy+iz \end{pmatrix} \begin{pmatrix} kx \\ ky \\ kz \end{pmatrix} \tag{8.2.157}$$

A trivial solution for a scaling is to put that $b=c=d=f=g=h=0$ from which the matrix form obvious diagonal k:

$$k = \begin{bmatrix} k & 0 & 0 \\ 0 & k & 0 \\ 0 & 0 & k \end{bmatrix} \tag{8.2.158}$$

This matrix is named "transformation matrix by scaling of center O (in this case the origin of the reference frame) and ratio k" and therefore the scaling being a diagonal matrix commutes with any linear application.

Obviously for the two dimensional case we have immediately:

$$\boxed{\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{bmatrix} k & 0 \\ 0 & k \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{bmatrix} W & 0 \\ 0 & H \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} kx \\ ky \end{pmatrix}} \tag{8.2.159}$$

where W is for "width" and H is for "height".

Remark

It should be noticed that as many planar shapes have their surface that depends on the multiplication of two of their geometrical parameters, as scaling of factor k has a squared effect of factor k on the surface. The same principle applied for a volume but it's cubic amplitude rather than a squared one.

In the case presented above, the scaling conserves the forms in all directions (its geometry is invariant under this transformation) if we use indeed the same factor k for all axes (we speak then of "uniform scaling"). But we may also use the following matrix:

$$k = \begin{bmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{bmatrix} \tag{8.2.160}$$

that would deforms the shape according to a different factor for each axis.

The inverse transformation of the scaling is obviously the scaling of center O and ratio k^{-1} thus in the form of a matrix:

$$k^{-1} = \begin{bmatrix} 1/k & 0 & 0 \\ 0 & 1/k & 0 \\ 0 & 0 & 1/k \end{bmatrix} \tag{8.2.161}$$

When the scaling center does not coincide with the origin of the selected coordinate system (which almost happens almost all the time), the procedure for calculating the coordinates of the image point is very simple. It is necessary to:

1. Carry out a translation to match the center of scaling with the origin of the frame and apply this translation to all points involved.
2. Make the scaling as described above (the center being the origin of the reference frame).
3. Make the reverse translation to take back the of center and the image in its original place.

To conclude, notice that the successive operations of translation and scaling are not commutative in the general case. In practice, we often performs first scaling and then translation as described in the three steps above.

8.2.6.3 Shear (skew) transformation

Definition (#8.2.343): In plane geometry, a "shear mapping" is a linear application that displaces each point in fixed direction, by an amount proportional to its signed distance from a line that is parallel to that direction.This type of mapping is also named "shear transformation", "transvection", or just "shearing".

Before formalize the general case of shear let us consider the following special case of a shearing factor k along the x axis:

$$\begin{pmatrix} x' \\ y' \end{pmatrix} \begin{bmatrix} 1 & k \\ 0 & 1 \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{bmatrix} 1 & 2 \\ 0 & 1 \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x+2y \\ y \end{pmatrix} \tag{8.2.162}$$

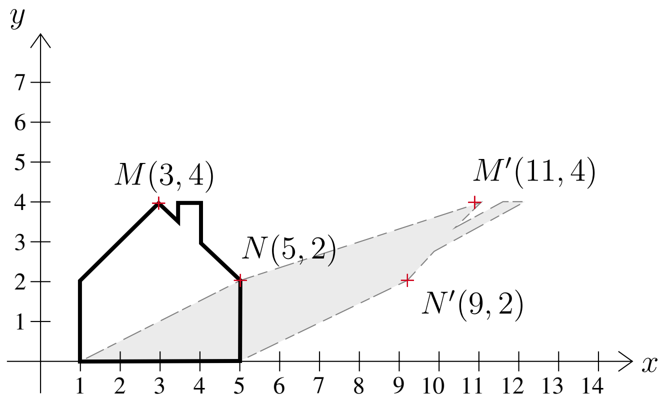


Figure 8.83: **Scaling with shear**

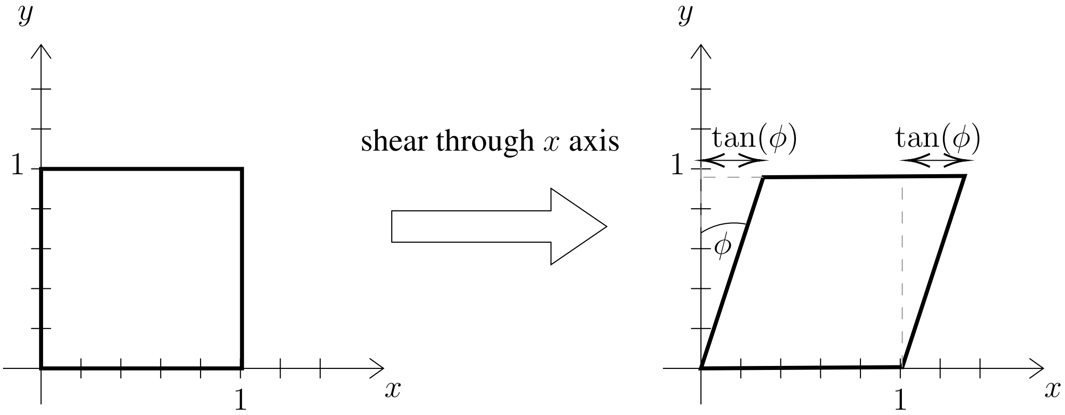
OK let us generalize that stuff! In fact for the shearing we must consider the case of shearing through the x-axis whose situation can be summarized by:



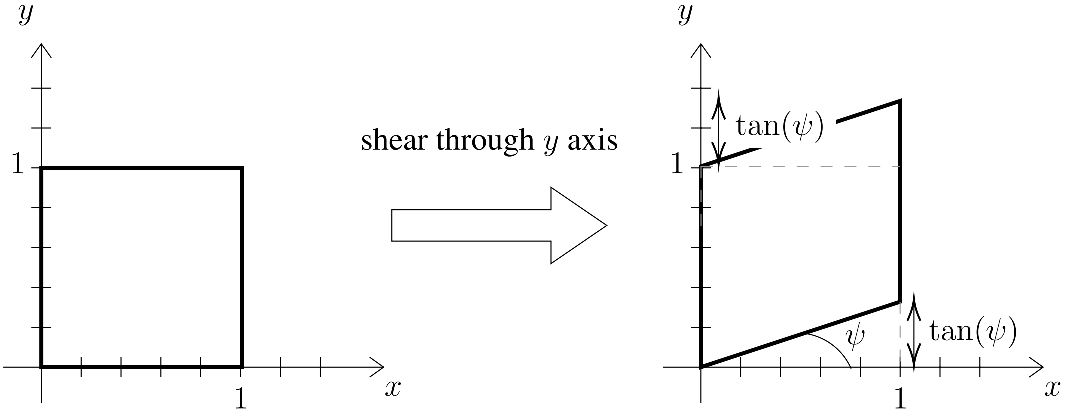
y
1
1
x
shear through x axis
y
$\tan(\phi)$
$\tan(\phi)$
1
ϕ
1
x

Figure 8.84: **Shearing trough x-axis**

So it is immediate that we have:

$$\boxed{\begin{pmatrix} x' \\ y' \end{pmatrix} \begin{bmatrix} 1 & \tan(\phi) \\ 0 & 1 \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x + y\tan(\phi) \\ y \end{pmatrix}} \tag{8.2.163}$$

and the case of shearing through the y-axis whose situation can be summarized by:



y
1
1
x
shear through y axis
y
$\tan(\psi)$
1
ψ

Figure 8.85: **Shearing trough y-axis**

So it is immediate that we have:

$$\boxed{\begin{pmatrix} x' \\ y' \end{pmatrix} \begin{bmatrix} 1 & 0 \\ \tan(\psi) & 1 \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x(\psi) \\ x\tan(\psi) + y \end{pmatrix}} \tag{8.2.164}$$

8.2.6.4 Rotation

Given any some form in the plane (point, line, oval, polygon, etc.), a real number α, and a point C located at a predefined location.

Definition (#8.2.344): A "rotation R" of angle α and of center C is the application that to every point M of the shape associates to the segment $\overline{CM}$ a new point, but having had a positive or negative angle of rotation α of center C such that $\overline{CM}$ and $\overline{CM'}$ have the same length but not same direction.

From this definition, it is apparent that the axis of rotation of an object is the locus of points of the object which remain stationary!

Remark

The rotation is also, in a more academic way, a bijective mapping in the plane, we can therefore also define a reciprocal transformation application denoted R^{-1}. But the rotation in the space is not bijective so we can not define a unique reciprocal transformation.

If $\alpha \neq 0$, then C is the only invariant point. If $\alpha = 2k\pi$ (with $k \in \mathbb{Z}$), then all points are invariant and the rotation is say to be of the type "identity rotation". If we choose an appropriate system of perpendicular axes such that their intersection coincides with C and that $\pm\pi$ then R is named a "rotation of central symmetry".

In another type of formalism, the rotation is expressed much more rigorously. We will help us with the drawing of a unit circle (in the plane) to study this type of transformation. We will consider the first case the origin of the reference and translation coincides:

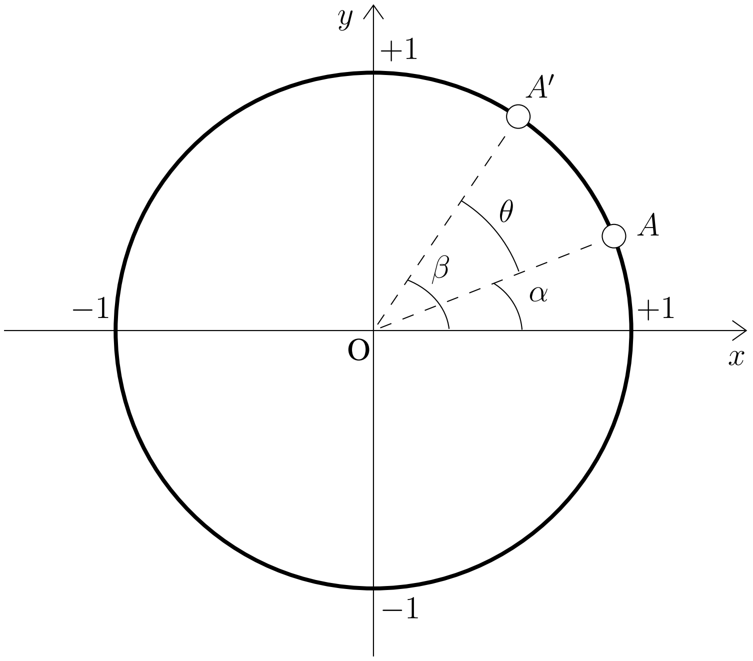

Figure 8.86: **Example of rotation in the plane**

where A' is the image of A by the rotation of center O and angle θ.

We have in the plane for the point A (see section Trigonometry page 2508):

$$x=r\cos(\alpha) \qquad y=r\sin(\alpha) \tag{8.2.165}$$

and identically for the point A':

$$x'=r\cos(\beta) \qquad y'=r\sin(\beta) \tag{8.2.166}$$

with $\beta=\alpha+\theta$.

Which brings us to write:

$$\dfrac{x}{\cos(\alpha)}=\dfrac{x'}{\cos(\alpha+\theta)}=r \tag{8.2.167}$$

Therefore using the Trigonometric identities (see section Trigonometry page 2519):

$$\begin{aligned}x'&=x\dfrac{\cos(\alpha+\theta)}{\cos(\alpha)}=x\dfrac{\cos(\alpha)\cos(\theta)-\sin(\alpha)\sin(\theta)}{\cos(\alpha)}=x\cos(\theta)-x\dfrac{\sin(\alpha)\sin(\theta)}{\cos(\alpha)}\\&=x\cos(\theta)-x\dfrac{y\sin(\theta)}{r\cos(\alpha)}=x\cos(\theta)-r\cos(\alpha)\dfrac{y\sin(\theta)}{r\cos(\alpha)}=x\cos(\theta)-y\sin(\theta)\end{aligned} \tag{8.2.168}$$

Identically (based on the fact that the basic trigonometric identities presented in the section Trigonometry of this textbook are known), we find:

$$y'=x\sin(\theta)+y\cos(\theta) \tag{8.2.169}$$

This allows us to write the rotation matrix in the plane (imagining that the z-axis out of the sheet/screen):

$$\begin{pmatrix}x'\\y'\end{pmatrix}=\begin{bmatrix}\cos(\theta) & -\sin(\theta)\\ \sin(\theta) & \cos(\theta)\end{bmatrix}\begin{pmatrix}x\\y\end{pmatrix}=\begin{bmatrix}x\cos(\theta) & -y\sin(\theta)\\ x\sin(\theta) & y\cos(\theta)\end{bmatrix} \tag{8.2.170}$$

Therefore the rotation matrix in the plane is given by:

$$\boxed{R=\begin{bmatrix}\cos(\theta) & -\sin(\theta)\\ \sin(\theta) & \cos(\theta)\end{bmatrix}} \tag{8.2.171}$$

The inverse transformation is simply the rotation of center O (same as before) but of angle $-\theta$ that is (we use obviously again the trigonometric relations of opposite angles):

$$R^{-1}=\begin{bmatrix}\cos(\theta) & \sin(\theta)\\ -\sin(\theta) & \cos(\theta)\end{bmatrix} \tag{8.2.172}$$

An easy way to see this is to notice that it is immediate that:

$$RR^{-1}=\begin{bmatrix}\cos(\theta) & -\sin(\theta)\\ \sin(\theta) & \cos(\theta)\end{bmatrix}\begin{bmatrix}\cos(\theta) & \sin(\theta)\\ -\sin(\theta) & \cos(\theta)\end{bmatrix}=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix} \tag{8.2.173}$$

When we want to make a rotation of an object around its barycenter (centroid) we should proceed as for the scaling, that is to say: bring the barycenter of the shape back to origin O of the reference frame with a translation, apply the rotation on the shape and only after take back the shape to its original position with a translation.

During the rotation of an object in space (we take the opportunity to introduce this now... because we need it in several on physics concepts that will follow in this textbook), the transformation is quite similar to the previous one except that the product of two rotations does not give a rotation and that it is not commutative when the number of dimensions is strictly greater than 2 (we can make the detailed calculation on request).

Indeed, during a rotation of angle ϕ around the z-axis coordinate, the coordinate z does not change. Which brings us to write the rotation matrix in three-dimensional space relatively to the plane $x-y$ as:

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \begin{bmatrix} \cos(\phi) & \sin(\phi) & 0 \\ -\sin(\phi) & \cos(\phi) & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = R_Z(\phi) \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} x\cos(\phi)+y\sin(\phi) \\ -x\sin(\phi)+y\cos(\phi)z \end{pmatrix} \tag{8.2.174}$$

For people reading this textbook on a computer with Adobe Flash player installed and activated, here is an animated version (otherwise see here: https://vimeo.com/575753732):

So therefore the rotation matrix application around the z axis of angle ϕ is:

$$\boxed{R_Z(\phi) = \begin{bmatrix} \cos(\phi) & \sin(\phi) & 0 \\ -\sin(\phi) & \cos(\phi) & 0 \\ 0 & 0 & 1 \end{bmatrix}} \tag{8.2.175}$$

So we can see that $R_Z(\phi)$ contains the rotation matrix in the plane $x-y$ that we have proved earlier above but with one more component according to the idea of homogeneous coordinates!!!

The philosophy is then always the same relative to other axes:

The three-dimensional rotation around the x-axis (relatively to the plane $z-y$) of angle θ:

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(\theta) & \sin(\theta) \\ 0 & -\sin(\theta) & \cos(\theta) \end{bmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = R_X(\theta) \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} x \\ y\cos(\theta)+z\sin(\theta) \\ -y\sin(\theta)+z\cos(\theta) \end{pmatrix} \tag{8.2.176}$$

For people reading this textbook on a computer with Adobe Flash player installed and activated, here is an animated version (otherwise see here: https://vimeo.com/575753223):

So therefore the rotation matrix application around the x axis of angle θ is :

$$\boxed{R_X(\theta)=\begin{bmatrix}1 & 0 & 0\\ 0 & \cos(\theta) & \sin(\theta)\\ 0 & -\sin(\theta) & \cos(\theta)\end{bmatrix}} \tag{8.2.177}$$

And finally the three-dimensional rotation around the y-axis (relatively to the plane $z-x$) of angle γ:

$$\begin{pmatrix}x'\\ y'\\ z'\end{pmatrix}=\begin{bmatrix}\cos(\gamma) & 0 & -\sin(\gamma)\\ 0 & 1 & 0\\ \sin(\gamma) & 0 & \cos(\gamma)\end{bmatrix}\begin{pmatrix}x\\ y\\ z\end{pmatrix}=R_Y(\gamma)\begin{pmatrix}x\\ y\\ z\end{pmatrix}=\begin{pmatrix}x\cos(\gamma)-z\sin(\gamma)\\ y\\ x\sin(\gamma)+z\cos(\gamma)\end{pmatrix} \tag{8.2.178}$$

OK for people reading this textbook on a computer with Adobe Flash player installed and activated, here is an animated version (otherwise see here: `https://vimeo.com/575753505`):

So therefore the rotation matrix application around the y axis of angle γ is:

$$\boxed{R_Y(\gamma)=\begin{bmatrix}\cos(\gamma) & 0 & -\sin(\gamma)\\ 0 & 1 & 0\\ \sin(\gamma) & 0 & \cos(\gamma)\end{bmatrix}} \tag{8.2.179}$$

We finally have three rotation matrices $R_X(\theta)$, $R_Y(\gamma)$, $R_Z(\phi)$ each corresponding to one of the planes (xy, yz, xz) of three-dimensional space. The three angles referred above are named "Euler angles" and sadly there is no convention in the notation of the angles, they depends on the authors and teachers.

These three matrices are part of the group of matrices of order three, denoted "SO (3)" and named by physicists and mathematicians "group of spatial rotations SO(3)" as seen in the section of Set Algebra at page 1425. Any rotation can be represented by the product matrix resulting from the product of these three (orthogonal) matrices (whose determinant is equal to 1 as proved in the section of Linear Algebra).

Remark

There is not only one eigenvector for one rotation matrix. There can be one but also a maximum of three. Indeed, consider a rotation of an object around the z-axis of π [rad] then obviously the z eigenvector $(0,0,1)$ with eigenvalues $-1,+1$ is obviously an eigenvector but also in this special case $(1,0,0)$ is an eigenvector but with an eigenvalue of -1.

Any rotation is a composition of these three rotations but it is important that the reader remembers the in the section of Linear Algebra where we saw that matrix multiplication is not commutative. Thus, rotation about the x-axis of $90°$ ($\pi/2$ [rad]) and the about the z-axis of $90°$ ($\pi/2$ [rad]) is not equivalent to rotate first around the z-axis and then around the x-axis by the same angle as shown in the figure below:

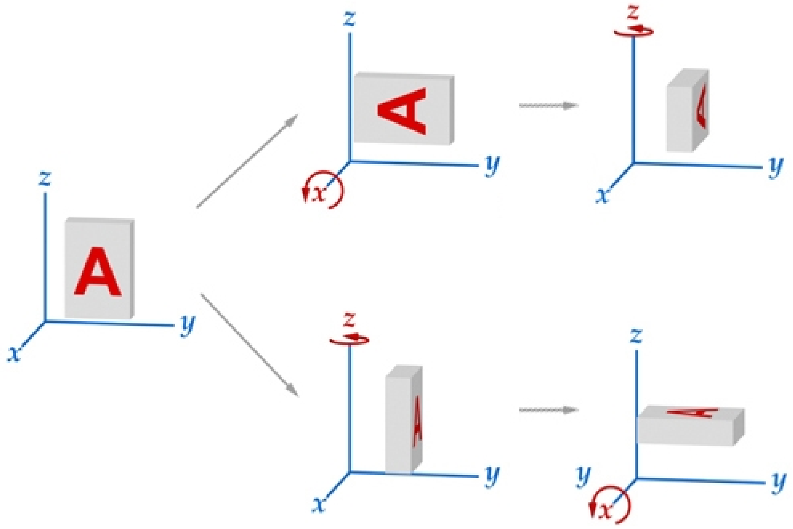

Figure 8.87: **Example of non-commutativity of the rotation matrix**

Finally, to get the matrix that makes up a particular case of the three rotations here for example are the commands to provide in Maple™ 4.00b:

```
>X:=array([[1,0,0],[0,cos(theta),sin(theta)],[0,-sin(theta),cos(theta)]]);
>Y:=array([[cos(lambda),0,-sin(lambda)],[0,1,0],[sin(lambda),0,cos(lambda)]]);
>Z:=array([[cos(phi),sin(phi),0],[-sin(phi),cos(phi),0],[0,0,1]]);
>evalm(X&*Y&*Z);
```

It is not very interesting to provide to our reader the expression of $R_{XYZ}=R_X R_Y R_Z$ as the rotations are not commutative and that therefore (excepted for some special cases) we have $R_{XYZ}\neq R_{XZY}\neq R_{YZX}\neq R_{YXZ}\neq R_{ZXY}\neq R_{ZYX}$. This is why most book don't give them (excepted some PDFs on Internet).

But as a reader requested it for R_{ZYX} let us give it:

$$\begin{aligned}R_{ZYX}&=\begin{bmatrix}\cos(\phi) & \sin(\phi) & 0\\ -\sin(\phi) & \cos(\phi) & 0\\ 0 & 0 & 1\end{bmatrix}\begin{bmatrix}\cos(\gamma) & 0 & -\sin(\gamma)\\ 0 & 1 & 0\\ \sin(\gamma) & 0 & \cos(\gamma)\end{bmatrix}\begin{bmatrix}1 & 0 & 0\\ 0 & \cos(\theta) & \sin(\theta)\\ 0 & -\sin(\theta) & \cos(\theta)\end{bmatrix}\\ &=\begin{bmatrix}\cos(\phi) & \sin(\phi) & 0\\ -\sin(\phi) & \cos(\phi) & 0\\ 0 & 0 & 1\end{bmatrix}\begin{bmatrix}\cos(\gamma) & \sin(\gamma)\sin(\theta) & -\sin(\gamma)\sin(\theta)\\ 0 & \cos(\theta) & \sin(\theta)\\ \sin(\gamma) & -\cos(\gamma)\sin(\gamma) & \cos(\gamma)\cos(\theta)\end{bmatrix}\\ &=\begin{bmatrix}\cos(\phi)\cos(\gamma) & \cos(\phi)\sin(\gamma)\sin(\theta)+\cos(\phi)\cos(\theta) & -\cos(\phi)\sin(\gamma)\sin(\theta)+\sin(\phi)\sin(\theta)\\ -\sin(\phi)\cos(\gamma) & -\sin(\phi)\sin(\gamma)\sin(\theta)+\cos(\phi)\cos(\theta) & \sin(\phi)\sin(\gamma)\sin(\theta)+\cos(\phi)\sin(\theta)\\ \sin(\gamma) & -\cos(\gamma)\sin(\gamma) & \cos(\gamma)\cos(\theta)\end{bmatrix}\end{aligned} \tag{8.2.180}$$

If we are looking to achieve the composition of a translation T and a rotation R and a scale scaling H the transformation matrix will be typically:

$$[R][H][T] \tag{8.2.181}$$

Remarks

R1. Let us recall (see section Linear Algebra page 1947) that the multiplication of two matrices is generally not commutative.

R2. The direct similarity of center C, of ratio R and angle α is the composite of the scaling of center C with ratio R and a rotation of center C and angle α. We refer the reader to the section Numbers to review that complex numbers (see page 243) allow to operate formally to similarities with the operations of addition and multiplication (direct or retrograde).

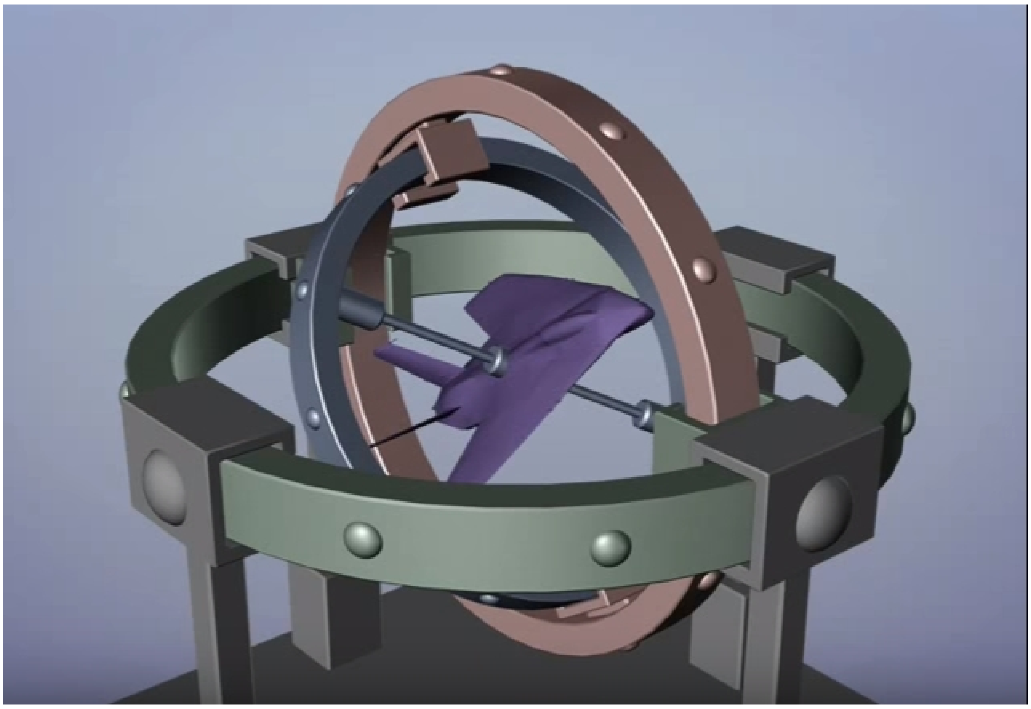
R3. We can make much more powerful and variable rotations using quaternions numbers (or "hypercomplex numbers"). For more information about this type of numbers the reader should refer to the section Numbers where the quaternions (see page 261) are introduced with a lot of details that makes more clear why they are preferred sometimes in 3D computing for rotations instead of the rotation matrices.

8.2.6.4.1 Gimbal lock

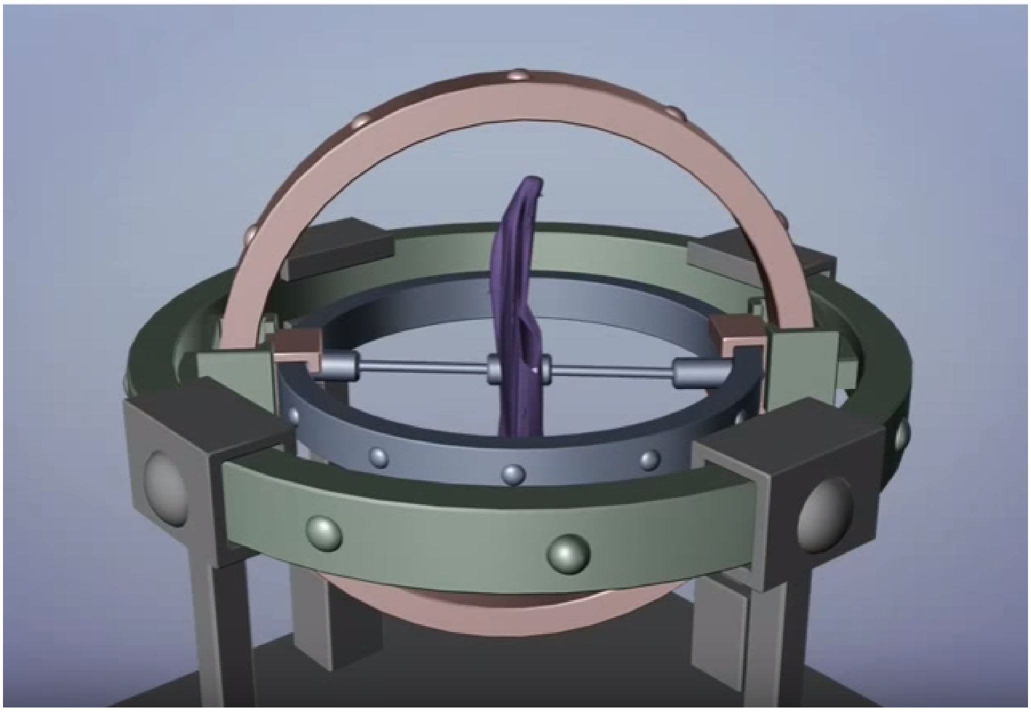
Gimbal lock is the loss of one degree of freedom in a three-dimensional, three-gimbal mechanism that occurs when the axes of two of the three gimbals are driven into a parallel configuration, "locking" the system into rotation in a degenerate two-dimensional space.

The problem of gimbal lock appears when one uses Euler angles (see further below the definition) in applied mathematics. Developers of 3D computer programs, such as 3D modelling, embedded navigation systems, robotics and video games must take care to avoid it.

Before going in the math stuff let us show an example of gimbal lock. Consider the following gyroscope like structure:



In the above configuration we can rotate the Jet in any angle (that means that a jet will know its position wherever it go) Indeed, the inner disc can rotate uniquely, same for the inner and outer disc. But now if the following configuration happens to occur:



The reader can then see that the inner disc then can only rotate around the same axis as the outer disc. So... yes!!! We lost one degree of freedom.

A lot of confusion results sometimes from the term "lock" in this issue. Indeed, we see from the above figure the gimbals don't actually "lock". They're all still free to spin about like they normally would, no ring is being held up or forcibly locked into position. It's only that if two of the three axis are aligned we can't say anymore the difference between rotating about one axis or another one. We can't because they're effectively the same axis in this special position. Both gimbals would rotate in the same direction at the same time.

So in certain orientations a way, pitch or roll axis aligns with one of the others. A that point, a change in the first can't be distinguished from a change in the other. That's a big problem if we need to keep track of our orientation accurately.

Remark

It is said that well-known gimbal lock incident happened in the Apollo 11 Moon mission.

In formal language, gimbal lock occurs because the map from Euler angles to rotations. Indeed, Euler angles provide a means for giving a numerical description of any rotation in three-dimensional space using three numbers, but not only is this description not unique, but there are some points where not every change in the target space (rotations) can be realized by a change in the source space (Euler angles). This is a topological constraint - there is no covering map from the 3-torus to the 3-dimensional real projective space; the only (non-trivial) covering map is from the 3-sphere, as in the use of quaternions.

A rotation in 3D space can be represented numerically with matrices in several ways. One of these representations is as we have just seen it:

$$R=R_ZR_XR_Y=\begin{bmatrix}\cos(\phi) & \sin(\phi) & 0\\ -\sin(\phi) & \cos(\phi) & 0\\ 0 & 0 & 1\end{bmatrix}\begin{bmatrix}1 & 0 & 0\\ 0 & \cos(\theta) & \sin(\theta)\\ 0 & -\sin(\theta) & \cos(\theta)\end{bmatrix}\begin{bmatrix}\cos(\gamma) & 0 & -\sin(\gamma)\\ 0 & 1 & 0\\ \sin(\gamma) & 0 & \cos(\gamma)\end{bmatrix}\tag{8.2.182}$$

Let us observe what happens if $\theta=0$ (that is to say we block the rotation around the x-axis):

$$R=R_ZR_XR_Y=\begin{bmatrix}\cos(\phi) & \sin(\phi) & 0\\ -\sin(\phi) & \cos(\phi) & 0\\ 0 & 0 & 1\end{bmatrix}\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}\begin{bmatrix}\cos(\gamma) & 0 & -\sin(\gamma)\\ 0 & 1 & 0\\ \sin(\gamma) & 0 & \cos(\gamma)\end{bmatrix}\tag{8.2.183}$$

Carrying out matrix multiplication:

$$\begin{aligned}R=R_ZR_XR_Y&=\begin{bmatrix}0 & 0 & -1\\ \sin(\phi) & \cos(\phi) & 0\\ \cos(\phi) & -\sin(\phi) & 0\end{bmatrix}\begin{bmatrix}\cos(\gamma) & \sin(\gamma) & 0\\ -\sin(\gamma) & \cos(\gamma) & 0\\ 0 & 0 & 1\end{bmatrix}\\ &=\begin{bmatrix}0 & 0 & 1\\ \sin(\phi)\cos(\gamma)-\cos(\phi)\sin(\gamma) & \sin(\phi)\sin(\gamma)+\cos(\phi)\cos(\gamma) & 0\\ \cos(\phi)\cos(\gamma)+\sin(\phi)\sin(\gamma) & \cos(\phi)\sin(\gamma)-\sin(\phi)\cos(\gamma) & 0\end{bmatrix}\end{aligned}\tag{8.2.184}$$

And finally using some of our trigonometry identities (see section Trigonometry page 2519):

$$R=\begin{bmatrix}0 & 0 & 1\\ \sin(\phi-\gamma) & \cos(\phi-\gamma) & 0\\ \cos(\phi-\gamma) & \sin(\gamma-\phi) & 0\end{bmatrix}=\begin{bmatrix}0 & 0 & 1\\ \sin(\phi-\gamma) & \cos(\phi-\gamma) & 0\\ \cos(\phi-\gamma) & -\sin(\phi-\gamma) & 0\end{bmatrix}\tag{8.2.185}$$

Changing the values of ϕ and γ in the above matrix has the same effects: the rotation angle $\phi-\gamma$ changes, but the rotation axis remains in the z direction! Indeed, we know that in a rotation matrix that when the first row and first column are fixed then we have a rotation around the x-axis, when the second row and second column are fixed then we have a rotation around the y-axis, when we the third a row and third column are fixed then we have a rotation around the z axis. So when the third column is fixed but instead of the third row it is the first row that is fixed than the rotation the last column and the first row in the matrix won't change. The only solution for ϕ and γ to recover different roles is to change θ.

In this specific situation, the gimbal lock behaviour can NOT be avoided. Quaternions (see page 261) can uniquely identify a rotation, but when they are converted into Euler rotations, they lose also one degree of freedom.

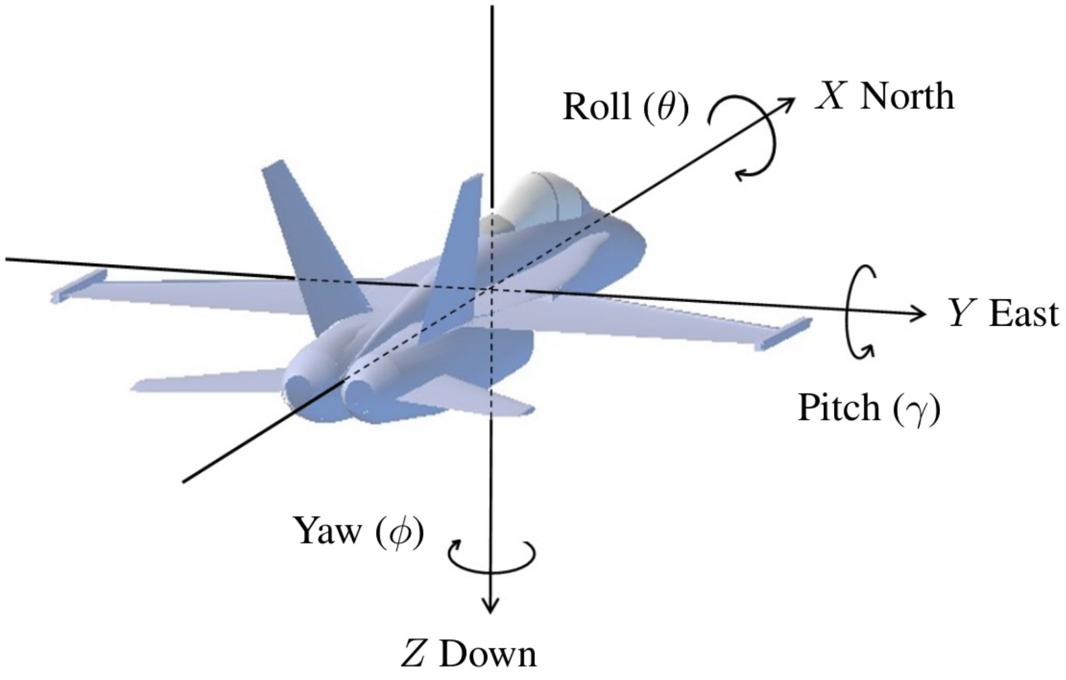


Figure 8.88: Vocabulary of rotation in aeronautical science

8.2.6.4.2 Euler angles

Let us come back on the Euler angles for an important result for our study late of the gyroscope effect in Classical Mechanics (especially the "nutation" effect)!

So we characterize a general orientation of a body with respect to the inertial system xyz (see figure below) in term of the following 3 rotations respectively by tradition the following order:

1. Rotation by angle ϕ around the z-axis
2. Rotation by angle θ around the new x_1' axis, which we name the "line of nodes".
3. Rotation by angle γ about the new x_3-axis

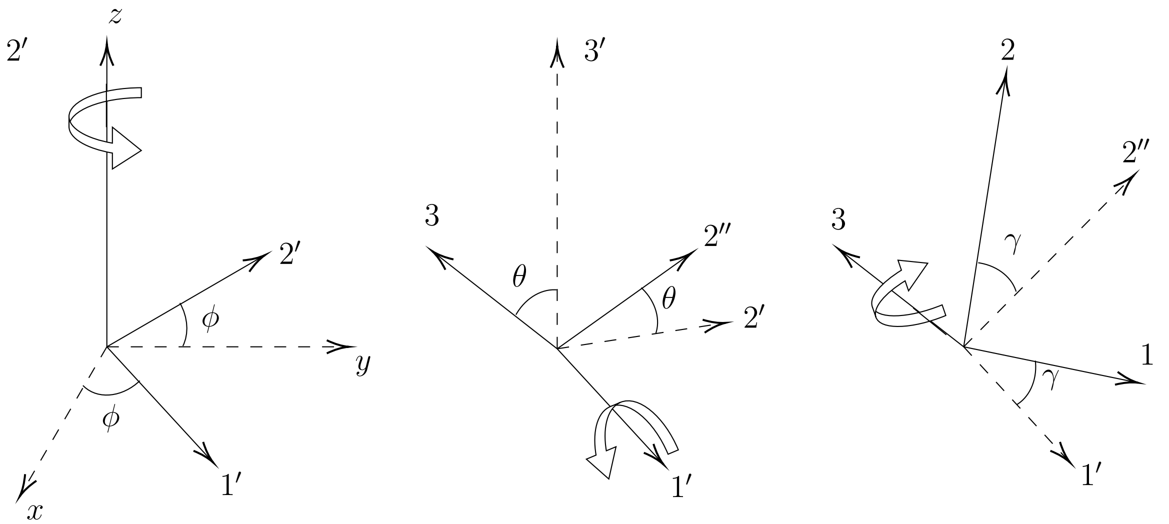

Figure 8.89: **Euler angles rotation convention**

Formally as we know this is given by:

$$R_{YXZ}=\begin{bmatrix}\cos(\gamma) & 0 & -\sin(\gamma)\\ 0 & 1 & 0\\ \sin(\gamma) & 0 & \cos(\gamma)\end{bmatrix}\begin{bmatrix}1 & 0 & 0\\ 0 & \cos(\theta) & \sin(\theta)\\ 0 & -\sin(\theta) & \cos(\theta)\end{bmatrix}\begin{bmatrix}\cos(\phi) & \sin(\phi) & 0\\ -\sin(\phi) & \cos(\phi) & 0\\ 0 & 0 & 1\end{bmatrix} \tag{8.2.186}$$

Fortunately, we most of time not have to use the resulting matrix of the three matrix multiplication above. In most kinematic problems what we really need is to be able to write the components of the angular velocity $\vec{\Omega}$ in both systems of coordinates. Since $\vec{\Omega}$ describes precisely how fast the angles vary in time, we have:

$$\boxed{\vec{\Omega}=\dot{\vec{\phi}}+\dot{\vec{\theta}}+\dot{\vec{\gamma}}=\frac{\mathrm{d}\vec{\phi}}{\mathrm{d}t}+\frac{\mathrm{d}\vec{\theta}}{\mathrm{d}t}+\frac{\mathrm{d}\vec{\gamma}}{\mathrm{d}t}=\dot{\phi}\vec{e}_z+\dot{\theta}\vec{e}_{1'}+\dot{\gamma}\vec{e}_3} \tag{8.2.187}$$

since the three rotations are about these particular axes.

Let us analyze each contribution to $\vec{\Omega}$:

1. $\dot{\vec{\phi}}=\vec{e}_z\dot{\phi}$ (with respect to xyz system). Following the rotations, we find that with respect to 123 system we have first (the reader can take the extreme situations where $\theta=0$ and $\theta=\pi/2$ to see that this is accurate):

   $$\vec{e}_z=\cos(\theta)\vec{e}_3+\sin(\theta)\vec{e}_{2''} \tag{8.2.188}$$

   but we notice that we also have with the same idea:

   $$\vec{e}_{2''}=\sin(\gamma)\vec{e}_1+\cos(\gamma)\vec{e}_2 \tag{8.2.189}$$

   Therefore we have:

   $$\vec{e}_z=\cos(\theta)\vec{e}_3+\sin(\theta)\vec{e}_{2''}=\cos(\theta)\vec{e}_3+\sin(\theta)\left(\sin(\gamma)\vec{e}_1+\cos(\gamma)\vec{e}_2\right) \tag{8.2.190}$$

   Hence:

   $$\dot{\vec{\phi}}=\dot{\phi}\vec{e}_z=\sin(\theta)\sin(\gamma)\dot{\phi}\vec{e}_1+\sin(\theta)\cos(\gamma)\dot{\phi}\vec{e}_2+\cos(\theta)\dot{\phi}\vec{e}_3 \tag{8.2.191}$$

   with respect to the 123 system.

2. $\dot{\vec{\theta}}=\vec{e}_{1'}\dot{\theta}$ (with respect to $1'2'3'$ system). Following the rotations, we find that with respect to 123 system we have obviously (the reader can take the extreme situations where $\gamma=0$ and $\gamma=\pi/2$ to see that this is accurate):

   $$\vec{e}_{1'}=\cos(\gamma)\vec{e}_1-\sin(\gamma)\vec{e}_2 \tag{8.2.192}$$

   Therefore:

   $$\dot{\vec{\theta}}=\vec{e}_{1'}\dot{\theta}=\left(\cos(\gamma)\vec{e}_1-\sin(\gamma)\vec{e}_2\right)\dot{\theta}=\cos(\gamma)\dot{\theta}\vec{e}_1-\sin(\gamma)\dot{\theta}\vec{e}_2 \tag{8.2.193}$$

   with respect to 123 system.

3. $\dot{\vec{\gamma}}=\vec{e}_3\dot{\gamma}$. Following the rotations, we have then immediately with respect to 123:

   $$\dot{\vec{\gamma}}=\vec{e}_3\dot{\gamma} \tag{8.2.194}$$

Therefore summing the relations:

$$\begin{aligned}\dot{\vec{\phi}}&=\sin(\theta)\sin(\gamma)\dot{\phi}\vec{e}_1+\sin(\theta)\cos(\gamma)\dot{\phi}\vec{e}_2+\cos(\theta)\dot{\phi}\vec{e}_3\\ \dot{\vec{\theta}}&=\cos(\gamma)\dot{\theta}\vec{e}_1-\sin(\gamma)\dot{\theta}\vec{e}_2\\ \dot{\vec{\gamma}}&=\vec{e}_3\dot{\gamma}\end{aligned} \tag{8.2.195}$$

Therefore the sum finely regrouped gives:

$$\vec{\Omega}=\left(\sin(\theta)\sin(\gamma)\dot{\phi}+\cos(\gamma)\dot{\theta}\right)\vec{e}_1+\left(\sin(\theta)\cos(\gamma)\dot{\phi}-\sin(\gamma)\dot{\theta}\right)\vec{e}_2+\left(\cos(\theta)\dot{\phi}+\dot{\gamma}\right)\vec{e}_3 \tag{8.2.196}$$

with respect to 123 system. Many times denoted:

The system:

$$\boxed{\begin{aligned}\Omega_1 &= \sin(\theta)\sin(\gamma)\dot{\phi}+\cos(\gamma)\dot{\theta}\\ \Omega_2 &= \sin(\theta)\cos(\gamma)\dot{\phi}-\sin(\gamma)\dot{\theta}\\ \Omega_3 &= \cos(\theta)\dot{\phi}+\dot{\gamma}\end{aligned}} \tag{8.2.197}$$

is named "kinematic Euler equations" and is very useful to express the rotation speed of a body in its own reference frame (most of time its center of mass).

Figure 8.90: Another common representation of Euler angles (author: Dorian Depriester)

8.2.6.5 Reflection

Definition (#8.2.345): The "reflection", also named "axial symmetry", denoted S_Δ (in geometry) relatively to the straight line Δ (in space the reflection is done relatively to a plane) is the application that associates to each point M outside Δ the point M' such that Δ is the mediator of $\overline{MM'}$. If M belongs to Δ, then $M = M'$.

Mathematically it is written:

$$S_\Delta : P \rightarrow P \Rightarrow S_\Delta(M) = M' \tag{8.2.198}$$

In other words, a transformation function of the type reflection of the entire plan in itself associates with each pre-image not more than a single image. Reflection is then a bijective function. So we can define a reciprocal transformation denoted S_Δ^{-1} such that:

$$S_\Delta^{-1}(M') = M \tag{8.2.199}$$

Remark

All points of Δ are trivially invariant under reflection in the plane.

The most obvious and well known reflection axes are those included into the shape itself as depicted with the examples visible in the figure below:

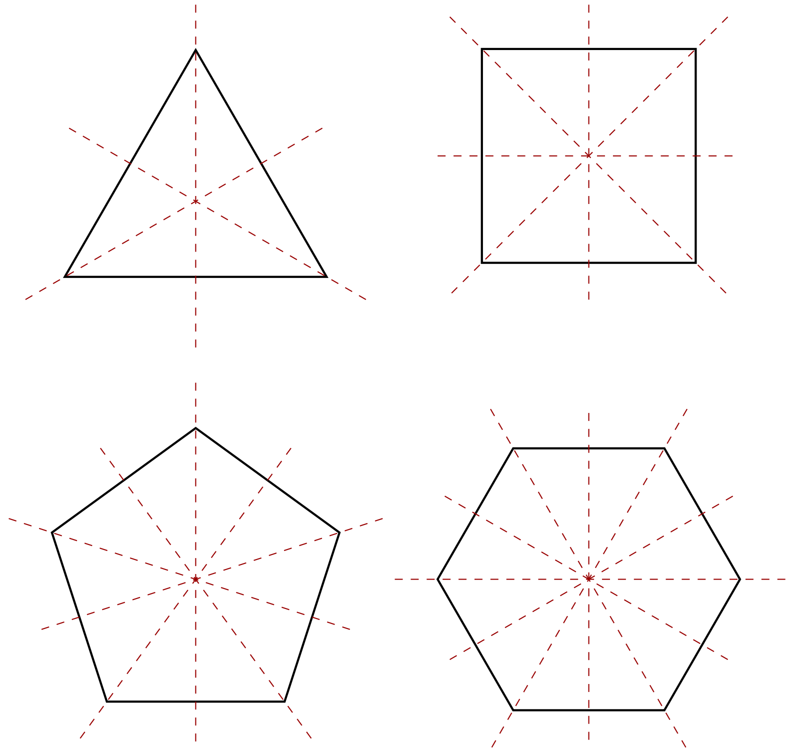

Figure 8.91: **Reflection axes (author: Lauren K. Williams)**

In matrix form the reflections in the plane are extremely simple to formalize using linear algebra (see section of the same name page 1924) as shown in the situations below:

- Reflection relatively to the y-axis:

$$S_{\Delta_y}=\begin{pmatrix}x'\\y'\end{pmatrix}=\begin{bmatrix}-1&0\\0&1\end{bmatrix}\begin{pmatrix}x\\y\end{pmatrix}=\begin{pmatrix}-x\\y\end{pmatrix}\tag{8.2.200}$$

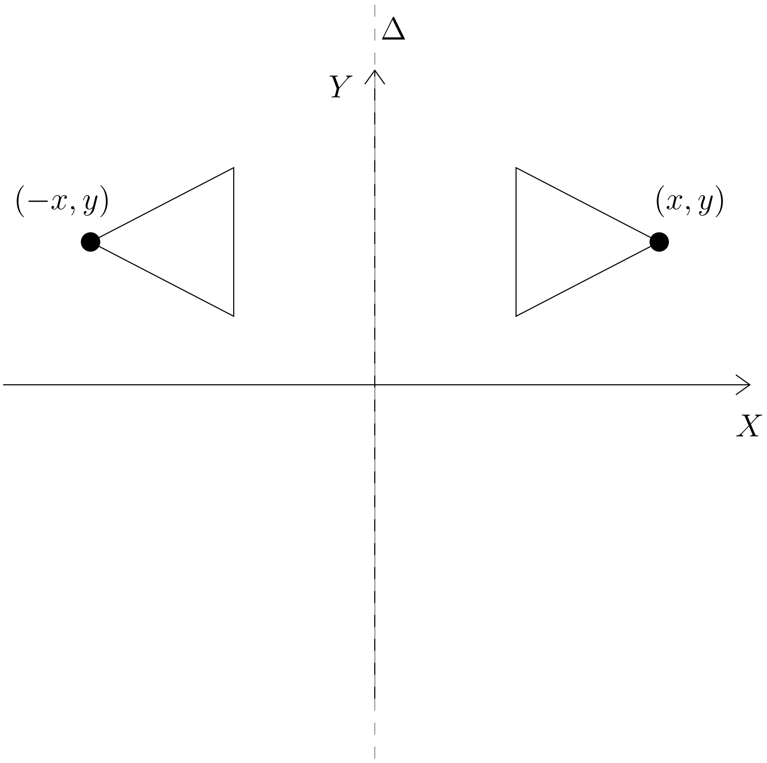

Figure 8.92: **Reflection around y-axis**

- Reflection relatively to the x-axis:

$$S_{\Delta_x}=\begin{pmatrix}x'\\y'\end{pmatrix}=\begin{bmatrix}1&0\\0&-1\end{bmatrix}\begin{pmatrix}x\\y\end{pmatrix}=\begin{pmatrix}x\\-y\end{pmatrix}\tag{8.2.201}$$

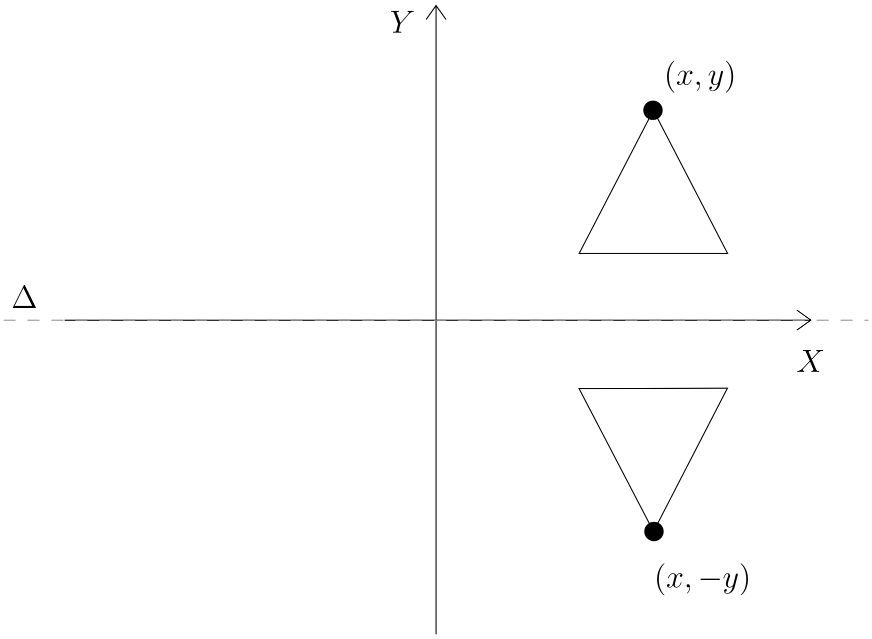

Figure 8.93: **Reflection around x-axis**

- Reflection relatively to the origin O:

$$S_{\Delta}=\begin{pmatrix}x'\\y'\end{pmatrix}=\begin{bmatrix}-1&0\\0&-1\end{bmatrix}\begin{pmatrix}x\\y\end{pmatrix}=\begin{pmatrix}-x\\-y\end{pmatrix}\tag{8.2.202}$$

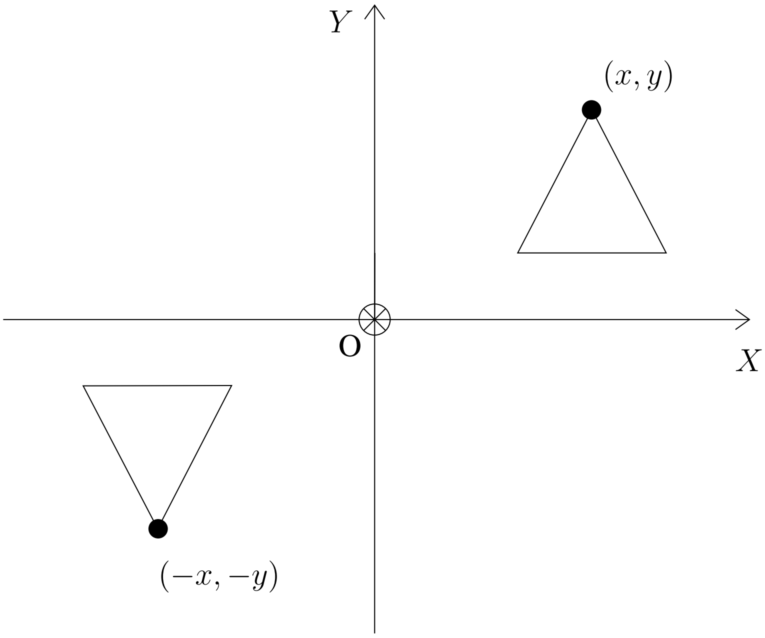

Figure 8.94: **Reflection around origin O**

The reader has very likely noticed that every reflection matrix is in fact only the special case of the plane rotation matrix and this was not difficulty to guess as we can see on every figure that a reflection is only a rotation around a special center of rotation.

Here is a quite good summary of what we have seen so far:

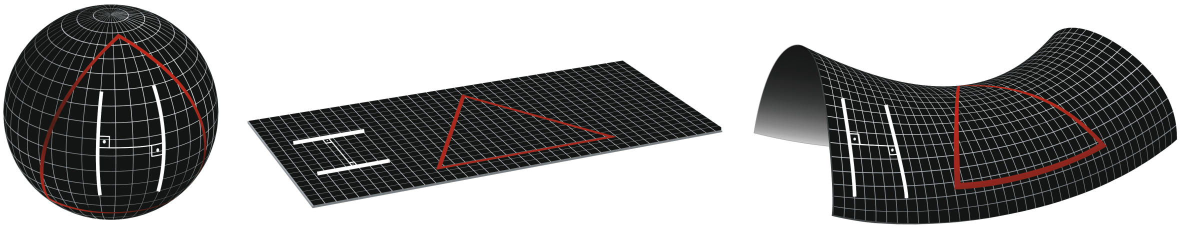
8.3. Non-Euclidean Geometry

ONE may recall from their lecture the section of Euclidean Geometry (see page 2563) that the sum of the angles in a triangle is 180 degrees. This comes from the Euclidean or "flat" geometry, which includes something named the "parallel postulate" (i.e. the 5th postulate) which states that if you were to draw two points next to one another, then extend from those points two lines that are parallel to one another, those lines could be extended to infinity without ever becoming closer together or further apart! This makes perfect intuitive sense; Euclidean geometry seems to be the structure of our world. However, our senses often deceive us. It turns out that gravity literally warps the geometry of space-time (for a naive and technical definition of "space-time" see the section of Special Relativity at page 5708) itself as we will see it in the section of General Relativity (see page 5720). That's right, because of the gravitational field, space-time is non-Euclidean (and there is some amount of gravity everywhere, since it is an interaction with infinite range). If not Euclidean, what can this geometry even be? As illustrated below, geometry on curved surfaces is a little different from geometry on flat (Euclidean) surfaces:



Positive curvature
(spherical like/elliptic)

Flat (zero) curvature
(plane like/euclidian)

Negative curvature
(horse's saddle like/hyperbolic)

Figure 8.96: **Positive (elliptic), negative (hyperbolic) and flat (euclidean) curves (source: NASA / WMAP Science Team)**

In a negatively curved ("hyperbolic") geometry, the sum of the angles in a triangle add up to less than 180 degrees (π radian), and parallel lines diverge from one another. In a positively curved geometry (also known as an "elliptic" geometry), the sum of the angles in a triangle add up to greater than 180 degrees (π radian) as proved in the section of Trigonometry, and parallel lines converge towards one another. A "flat" geometry, the Euclidean case, has zero curvature. It is a special case that is the exact point in between hyperbolic and elliptic geometries and in such an euclidean geometry the sum of the angles of a triangle is always equal to 180 degrees (π radian) as proven at page 2593. Another illustration below shows the failure of the parallel postulate in non-Euclidean spaces.

Therefore we guess obviously that non-Euclidean geometries are all geometries that not necessarily satisfy all the Hilbert's axioms (see section Euclidean Geometry page 2631) but without any contradiction between them (unlike the old axioms of Euclid, particularly that on parallels).

A particular representation of this type of geometry consists to define the points as being distributed over the surface of a sphere (that are the intersection of the diameters of the sphere with the surface), and the lines, to generalize the concept of straight line (now we say "geodesic"), as the intersections of the surface of the sphere with the planes containing the center of the sphere.

Two points then define uniquely a line and a point is always given by the intersection of two lines. However, in this geometry, if we give ourselves a line AB and a external point P to the line, there is no line passing through P and not intersecting AB. So Euclid's fifth postulate is not satisfied because in P we can not draw any parallel to AB.

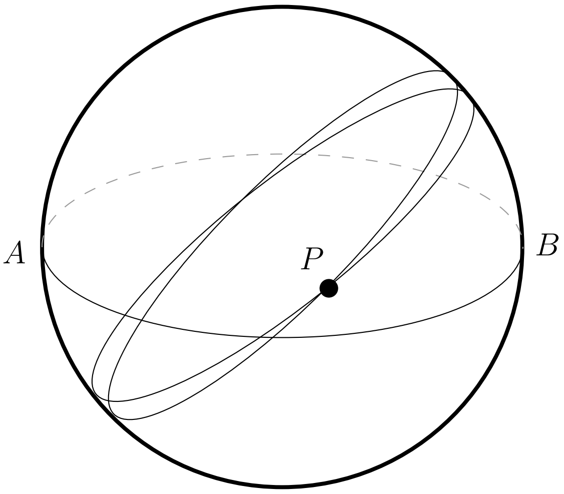


Figure 8.97: **Illustrated example of the violation of the fifth Euclide postulate**

Remark

Before starting this section, we strongly recommend the reader to consult and if possible to understand the content of the section on Trigonometry, Euclidean Geometry and Tensor Calculus as we will use many results, not necessarily trivial, we have proved in them.

In section on Euclidean Geometry, we studied a number of theorems related to plans. Let us insist on the fact that the "plane" is a two-dimensional figure whose curvature is null and immersed in a 3-dimensional space (therefore the plane can be moved in it). This said, it should perhaps now necessary to define a little bit more rigorously the intuitive concept of "curvature(s)".

8.3.1 Curvature(s)

Definition (#8.3.346): A figure is said to be "curved" if there is at least one point lying on the straight or straights defining the bounds of the figure (surfaces, volumes, etc.) defining a tangent on the bound and not crossing the bound elsewhere.

This is Friedrich Gauss who in 11824 (holocene calendar) had formulated the possibility that there are alternatives to Euclidean geometries. We distinguish between geometries with "negative curvature", like the one of the Russian Nikolai Lobachevsky (11829 according to holocene calendar) and Bolyai (11832 according to holocene calendar) (sum of angles of a triangle below π, infinite number of possible parallel to a line through a point), from geometries with "positive curvature" as the Riemann (11867 according to holocene calendar) one (sum of the angles of a triangle greater than π, parallel joining to the poles).

We will see in this section various non-Euclidean geometries, the best known are the "Riemannian geometries" (constant curvature) and "Lobachevsky geometries" (hyperbolic type with non-constant curvature).

Remark

The geometry commonly named "Riemann geometry" is a three-dimensional spherical space, finite space but boundless, with regular curvature, alternative to the Euclidean postulate on parallels.

The interest in the study of these geometries is that we can't determine whether the Universe we live in is made of a type of geometry rather than another because given our (physical) size, immersed we are in any geometry whatsoever with low curvature, any surface space seems locally Euclidean to us (two parallel lines do not intersect). However, in General Relativity, which makes an excessive us of tensor calculus (generalization of any geometry as seen in the section on Tensor Calculus at page 2038) shows that there are region of the space where the geometry is strongly curved and therefore locally non-Euclidean and only the study of this kind of geometries allows us to draw theories explaining observations that are not exploitable only with human intuition.

A distinction has also to be made between "intrinsic curvature" and "extrinsic curvature[4]". The easy to visualize curvature is extrinsic. The physically meaningful curvature is intrinsic! Intrinsic curvature is what General Relativity deals with! Imagine a sheet of paper laid flat on a table. On this paper is a bug. The bug walks along the shortest path on the paper from point A to point B. We can all agree that the paper is flat and that the line is straight. Now roll up the paper into a tube. Again the bug walks along the shortest path from point A to point B. The bug will have walked across the exact same path on the paper (assuming that the shortest path does not cross the seam). From the point of view of the paper, the path is straight. From our external point of view, the paper is curved and the path follows the paper. The above is an example of extrinsic curvature. We have a two dimensional space (the paper) and a larger three dimensional space (our ordinary three dimensional geometry) in which it is embedded. The curvature of the path depends on how we roll up the paper, i.e. how we choose to do the embedding. For an inhabitant living on the surface of the paper using measurements made only on that surface, extrinsic curvature is not detectable.

---

[4] As a common question on Internet is that a space can only be curved in relation to an absolute "straight space"? Otherwise we would never know that it is curved. There must be an absolute straight space geometry underlying the curved space?

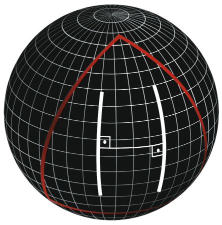
Extrinsic curvature is a property of the embedding. The bug traces out the same path on the paper, whether it is rolled or unrolled. It is only from our external viewpoint that we can see any "curvature". In the case of a sphere, things are not so simple. We cannot roll up a flat sheet of paper into a sphere without stretching or wrinkling it. If the bug on a sphere follows shortest paths and keeps careful track of distances, he can notice that the surface he lives on is not Euclidean. The interior angles of a triangle will sum to more than 180 degrees as we have already proved in the section of Trigonometry. The above is an example of intrinsic curvature. For an inhabitant living on the surface of the paper using measurements made only on that surface, intrinsic curvature is detectable. Here comes the hard part... In the examples above, we talked about a two dimensional surface embedded within a three dimensional Euclidean space. That was just an aid to visualization. We can talk about the geometry of a two (or three or four or more) dimensional space without requiring that it be embedded in a higher dimensional space at all. A common way to do that is to imagine that the inhabitants of the space are able to measure distances. From any point in the space to any other point in the space, they can measure the distance between them. The distance measurement is the mathematical notion of a "metric". A space for which a metric exists is named a "metric space" as we know it. Given a metric space, one can define intrinsic curvature in terms of the metric. A standard way of handling a metric space in physics is to divide it up (if needed) into pieces and equip each piece with a Cartesian coordinate system. There are some rules about the boundaries and how to handle the seams between the pieces that we need not concern ourselves with. The result is a "manifold". A surface of a sphere can be modelled as a two dimensional manifold. There is no embedding in three dimensional space and no meaningful notion of extrinsic curvature. There is still non-zero intrinsic curvature for this space.

Definition (#8.3.347): "Intrinsic curvature" comes from the parallel translation of a vector tangent to the path of translation. If a vector is translated around a loop and it fails to come back onto itself that is intrinsic curvature (see an example in the section of Tensor Calculus page 2114). "Extrinsic curvature" is computed by the parallel translation of a vector normal to a surface or space. If the translated normal deviates from the normal vector at a point the difference in the two normal vectors defines the extrinsic curvature for a unit of translation along the space.

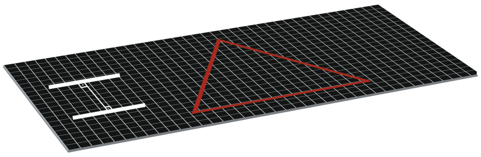
Before we tackle formally and with an abstract manner to certain non-Euclidean geometries we will first make a pragmatic and specific introduction of certain concepts that we are not totally foreign for because already covered in other section theoretically. Once made this introduction, which will be very useful pedagogically, we will address these concepts more rigorously.

8.3.2 Axioms of non-euclidean geometry

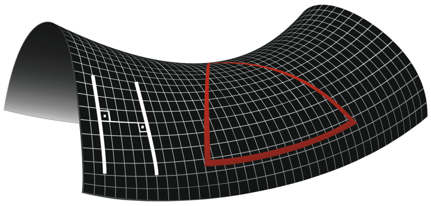
To obtain a non-Euclidean geometry, the parallel postulate A.P1 (or its equivalent) that we have seen during our study of Euclidean Geometry must be replaced by its negation (A.NP1). Everything that follows is related to that figure again:



Positive curvature
(spherical like/elliptic)



Flat (zero) curvature
(plane like/euclidian)



Negative curvature
(horse's saddle like/hyperbolic)

Then the axiom of parallels becomes:

A.NP1. The also named "Lobachevsky axiom" or "Hyperbolic Parallel Postulate (HPP)" assume that there exist at least two lines passing through the given point P not located on a given line and parallel to this line (we speak then of "two diverging ultra-parallel lines").

An alternative and more easy formulation is:

A.NP1'. There exist a line L and a point P not on L such that at least two distinct lines parallel to l pass through P. In other words: Through a point not on a line there is more than one line parallel to the given line!!!

The above form of the axiom of parallelism ensures the existence of an infinite number of parallel lines satisfying the given conditions. Geometric space defined by the axiomatic system including Lobachevsky axiom is named "hyperbolic non-Euclidean geometry". Geometry of the curved surface hyperboloid can be described as a hyperbolic geometry. In the hyperbolic space, the interior angles in an arbitrary triangle is less than π.

A second possible form of the negation of axiom of parallelism is as follows:

A.NP1. There exist no line passing through the given point not located on a given line and parallel to this line.

The geometric space defined by this last axiomatic system is named "elliptic non-Euclidean geometry". Geometry of the sphere (spherical geometry) can be regarded as elliptic geometry. In the elliptic space, the interior angles in an arbitrary triangle is greater than π (see the proof just below).

8.3.3 Generalized angle sum theorems

We have already proven the angle sum theorem for the euclidean geometry earlier in the section Trigonometry at page 2593. Let us see now a very important practical case for non-euclidean geometries: the case of the sphere!

To prove that for the spherical case the sum of the angles of a triangle is greater than 180 degrees (π radian), we first need to introduce the concept of Lune on a sphere.

Definition (#8.3.348): In spherical geometry, a "spherical lune" (or "biangle") is an area on a sphere bounded by two half great circles which meet at antipodal points.

Given the figure below that will be of main interest for us later:

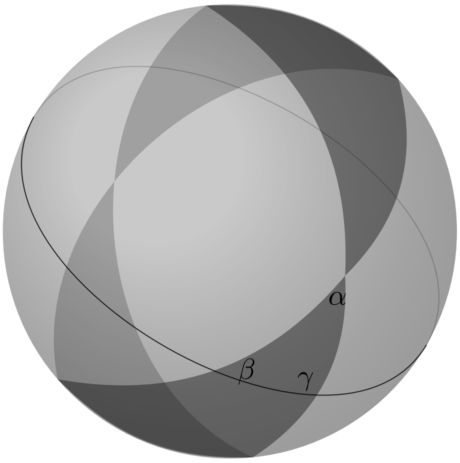


Figure 8.98: **Lunes in a sphere**

where we have 6 lunes denoted $L(\alpha)$, $L(\bar{\alpha}$, $L(\beta)$, $L(\bar{\beta})$, $L(\gamma)$ and $L(\bar{\gamma})$.

We know that the surface of a sphere is $4\pi R^2$ (see page 2964), the surface of a Lune of angle θ is therefore straightforward:

$$S_{\text{Lune}}(\theta)=4\pi R^2\frac{\theta}{2\pi}=2\theta R^2 \tag{8.3.1}$$

Now that we have introduce what a Lune is and how to compute its surface we can prove the angle sum theorem for a spherical non-euclidean space!

Consider the three angles α, β, and γ of the triangle visible on the sphere in the figure above.

The six lunes defined by the angles of the triangle encompass the entire sphere as well as overlapping the triangle area in the front and rear of the sphere 4 extra times. Thus, we begin with the radius of a sphere plus 4 times the area of the triangle is equal to the 6 lunes.

Therefore:

$$4\pi R^2+4S_{\alpha\beta\gamma}=2L(\alpha)+2L(\beta)+2L(\gamma) \tag{8.3.2}$$

Simplifying we get:

$$2\pi R^2 + 2S_{\alpha\beta\gamma} = L(\alpha) + L(\beta) + L(\gamma) \tag{8.3.3}$$

At this point we need to use a the previous result that states that a lune whose corner angle is θ radians has area $2\theta R^2$:

$$2\pi R^2 + 2S_{\alpha\beta\gamma} = 2\alpha R^2 + 2\beta R^2 + 2\gamma R^2 \tag{8.3.4}$$

Hence:

$$2\pi R^2 + 2S_{\alpha\beta\gamma} = 2R^2(\alpha + \beta + \gamma) \tag{8.3.5}$$

Therefore:

$$\pi + \frac{S_{\alpha\beta\gamma}}{R^2} = \alpha + \beta + \gamma \tag{8.3.6}$$

So as ${}^{S_{\alpha\beta\gamma}}/_{R^2} > 0$, we have finally:

$$\alpha + \beta + \gamma > \pi \tag{8.3.7}$$

This result is sometimes named the "spherical triangle theorem".

As we have proved for the flat euclidean geometry that $\alpha + \beta + \gamma = \pi$ and just now for the spherical non-euclidean geometry that $\alpha + \beta + \gamma > \pi$, therefore by deduction for the hypergeometric non-euclidean geometry we have $\alpha + \beta + \gamma < \pi$.

8.3.4 Geodesic and Metric Equation

Let us come back on the concepts of geodesic and curvature which we have often mentioned in the section of Tensor Calculus (the fact of not having read the section of Tensor Calculus is normally not a problem in understanding what follows).

Consider, as an introduction example, the two-dimensional surface of a sphere of radius R. Given two points B and C diametrically opposed, we seek the shortest distance s measured on the sphere between B and C. The curve we get is as we know a "geodesic", a concept that generalizes therefore, for an arbitrary surface, the notion of the straight lines for planes:

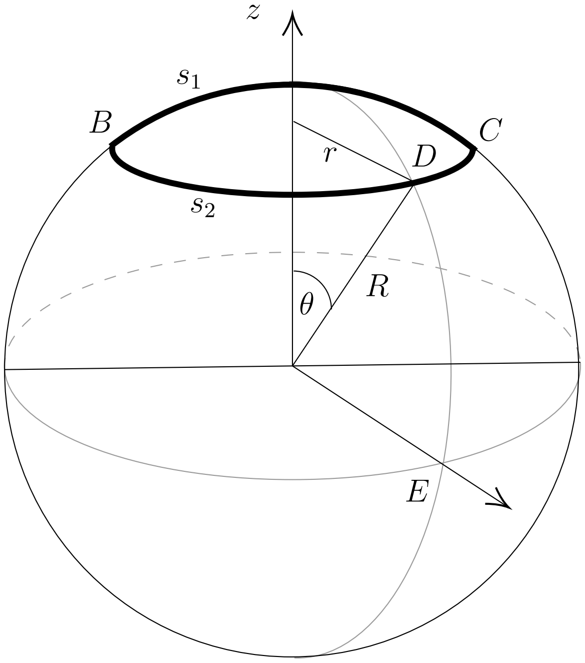

Figure 8.99: **Illustration of the problem to research the geodesic on a sphere**

Remark

We assume as intuitive that the length of a curve in the three-dimensional Euclidean space is always greater than or equal to the length of any planar projection of this curve. The geodesic curve is therefore necessarily a plane curve.

The radius between the axis Oz and one of the points B and C is trivially given by some elementary trigonometry (see section Trigonometry page 2519):

$$r = R\sin(\theta) \tag{8.3.8}$$

And therefore the half circumference of the circle at the height of B and C is given by:

$$s_2 = \frac{P_2}{2} = \frac{2\pi R\sin(\theta)}{2} = \pi R\sin(\theta) \tag{8.3.9}$$

And we have proved it in the section of Trigonometry that the perimeter of a circle depending on the opening angle of the latter was given by (α must be in radians!):

$$L = R\alpha \tag{8.3.10}$$

It therefore comes automatically:

$$s_1 = R2\theta \tag{8.3.11}$$

Finally:

$$\begin{aligned} s_1 &= R2\theta \\ s_2 &= R\pi\sin(\theta) \end{aligned} \tag{8.3.12}$$

A plot or Taylor approximation shows easily that $\pi\sin(\theta) \geq 2\theta$ on the interval $[0,\pi/2]$ then on the same interval $s_2 \geq s_1$ (there is equality in $\theta = 0$ and $\theta = \pi/2$).

The geodesics of the sphere are therefore the big circles arcs s_1, paths taken by aircraft for inter-continental flight (in empty space, without wind and perfect spherical planet), and correspond to the lines obtained between the surface of the sphere and a plane passing through the center thereof!

The geometrical properties of figures drawn on the surface of a sphere are obviously no longer those of Euclidean Geometry. Thus, the shortest path from point B to point C on the spherical surface, consists of a great circle passing through the points B and C plotted on a plane passing through the center of the sphere. Great circle arcs play the same role for the sphere that lines in the plane. These are the "geodesic" of the sphere.

Now consider two dimensional surfaces: the surface of the sphere and that of the cylinder. Given two points B and C, we trace the geodesic curve between these points:

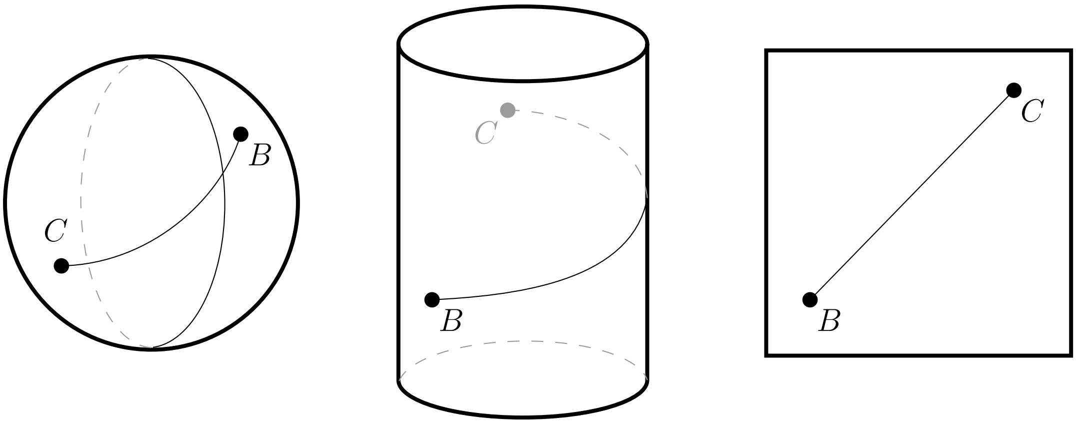

Figure 8.100: **Some geodesics of trivial surface on trivial volumes**

The cylinder may be cut parallel to its axis and unfolded flat. The geodesic thus appears as a straight line of the plane! We say then that the cylinder is "inherently flat" (even if its topology is different from the plane, we must especially avoid that the cut crosses the geodesic). This is intuitively obviously not the case of the surface of the sphere.

In the case of the cylindrical surface, we can define the Cartesian coordinates of the plane $B(y_1,z_1)$ and $C(y_2,z_2)$ that permits to write the length s of the curve (straight line) BC with the Pythagorean theorem:

$$s^2=(y_2-y_1)^2+(z_2-z_1)^2 \tag{8.3.13}$$

The metric of the plane is Euclidean and under infinitesimal form we get the "Euclidean metric equation":

$$\mathrm{d}s^2=\mathrm{d}y^2+\mathrm{d}z^2 \tag{8.3.14}$$

On the cylinder, the change of variable gives $y=r\theta$ (with the angle in radians!):

$$\mathrm{d}s^2=(r\theta_2-r\theta_1)^2+(z_2-z_1)^2=r^2(\theta_2-\theta_1)^2+(z_2-z_1)^2 \tag{8.3.15}$$

Or under local form:

$$\mathrm{d}s^2=r^2\mathrm{d}\theta^2+\mathrm{d}z^2 \tag{8.3.16}$$

The surface of the cylinder can thus be represented by Cartesian coordinates similar to those of the plane, the metric of the cylinder surface being Euclidean under infinitesimal form and under global form.

Remark

The previous relation is what we got in the section of Tensor Calculus for the metric equation in polar coordinates.

We can interest us now to the problem to write the analogue of Pythagorean theorem to a spherical surface. The impossibility to cut the ball and flatten it to marry a plane suggests some difficulties...

That is why the equation of the metric can't be written in general form as the Pythagorean theorem. Indeed, we proved in the section of Tensor Calculus (page 2099) that this latter was given for a spherical surface by:

$$\mathrm{d}s^2=\mathrm{d}r^2+r^2\mathrm{d}\theta^2+r^2\sin^2(\theta)\mathrm{d}\phi^2 \tag{8.3.17}$$

However, locally (that is to say in a small region of small dimension relatively to the radius of the sphere), the properties of the sphere can be described by Cartesian coordinates of a plane tangent to the surface (the essential property of Riemann spaces) as the metric equation is locally Euclidean!:

$$\mathrm{d}s^2\cong r^2\mathrm{d}\theta^2+r^2\sin^2(\theta)\phi z^2 \tag{8.3.18}$$

By writing:

$$\mathrm{d}\xi=\sqrt{g_{\theta\theta}}\mathrm{d}\theta \qquad \mathrm{d}\eta=\sqrt{g_{\phi\phi}}\mathrm{d}\phi \tag{8.3.19}$$

We therefore have:

$$\mathrm{d}s^2\cong g_{\theta\theta}\mathrm{d}\theta^2+g_{\phi\phi}\mathrm{d}\phi^2=\mathrm{d}\xi^2+\mathrm{d}\eta^2 \tag{8.3.20}$$

with:

$$g_{\theta\theta}=r^2 \qquad g_{\phi\phi}=r^2\sin^2(\theta) \tag{8.3.21}$$

While (θ,ϕ) are the "Gauss coordinates", (ξ,η) are the "Riemann coordinates" of the locally tangent plane. Thus, we notice that Euclidean space is a special case of Gauss coordinates for which we have (see section Special Relativity page 5704):

$$\begin{aligned}\mathrm{d}s^2&=g_{ij}\mathrm{d}x^i\mathrm{d}x^j=g_{11}\mathrm{d}u\mathrm{d}u+g_{12}\mathrm{d}u\mathrm{d}v+g_{21}\mathrm{d}v\mathrm{d}u+g_{22}\mathrm{d}v\mathrm{d}v\\&=1\mathrm{d}u\mathrm{d}u+0\mathrm{d}u\mathrm{d}v+0\mathrm{d}v\mathrm{d}u+1\mathrm{d}v\mathrm{d}v=\mathrm{d}u^2+\mathrm{d}v^2\end{aligned} \tag{8.3.22}$$

and thus the metric tensor is a identity matrix (the diagonal elements are equal to 1 the rest being zero):

$$g_{ij}=\begin{bmatrix}1&0\\0&1\end{bmatrix} \tag{8.3.23}$$

The reader will have perhaps noticed that if we take the vector basis of the polar coordinates as seen in the section of Vector Calculus but without normalizing them to then unit (that is to say without dividing the first vector by r and the second by $\sin(\theta)$) we have:

$$g_{ij}=\vec{e}_i\circ\vec{e}_j \tag{8.3.24}$$

with $i,j=\{\theta,\phi\}$ and so on for every other coordinate system.

8.3.5 Riemann Spaces

To better understand what is a Riemann space, we will now go through a small example of a two-dimensional surface (classic example):

Consider a sphere of radius r, of surface S, located in the ordinary three-dimensional space. The Cartesian coordinates x,y,z of a point M on the surface S can be expressed, for example, depending on the spherical coordinate (r,θ,ϕ) (see section Vector Calculus page 1849). The sphere is fully described for a given radius r and $0 \leq \phi < 2\phi$ and $0 \leq \theta < \pi$.

Three such parameters, giving the possibility to determine a point on the surface of a sphere, are as we know (see section Tensor Calculus page 2092) curvilinear coordinates of the surface or also named "Gaussian coordinates" (Gauss being one of the first mathematicians interested in the study of bodies immersed in non-Euclidean spaces). Other arbitrary parameters u,v,w may of course be chosen as curvilinear coordinates on the surface.

The linear element $\mathrm{d}s^2$ of the surface, square distance between two infinitely close points M,M', is written based on spherical coordinates, as we have seen in the section of Tensor Calculus and just above:

$$\mathrm{d}s^2 \cong r^2\mathrm{d}\theta^2 + r^2\sin^2(\theta)\mathrm{d}\phi^2 \tag{8.3.25}$$

We thus obtain an expression of the linear element based on only the three Gauss coordinates (r,θ,ϕ). We could of course impose a local study (tangent plane) so that the linear element is only function of (θ,ϕ) as we have seen above:

$$\mathrm{d}s^2 \cong r^2\sin^2(\theta)\mathrm{d}\phi^2 \tag{8.3.26}$$

Written using the three parameters, the surface of the sphere (considered as a two-dimensional space) is an example of two-dimensional Riemann space whose linear element is in the general form well known (see the chapter of tensor calculus):

$$\mathrm{d}s^2 = g_{ij}\mathrm{d}u^i\mathrm{d}u^j \tag{8.3.27}$$

where the $\mathrm{d}u^i, \mathrm{d}u^j$ are the contravariant components of the vector $\mathrm{d}\vec{M} = \overrightarrow{MM'}$ relatively to the referential denoted by $(M,\vec{e}_j)$.

Remark

The study of figures on Riemannian surfaces is part of differential geometry to which we devote a whole section in this chapter.

Now consider any surface of coordinates u^1,u^2. The Cartesian coordinates x,y,z of ordinary space where this surface is dived are written in general terms with the Gauss coordinates:

$$x = x(u^1,u^2) \qquad y = y(u^1,u^2) \qquad z = z(u^1,u^2) \tag{8.3.28}$$

Remember also that the metric equation can be written in tensorial notation:

$$\mathrm{d}s^2 = g_{ij}\mathrm{d}u^i\mathrm{d}u^j \tag{8.3.29}$$

can be written in an expanded form as follows (this is proved in details with a geometric approach in the section of Differential Geometry at page 2880):

$$\boxed{\mathrm{d}s^2=E\mathrm{d}u^2+2F\mathrm{d}u\mathrm{d}v+G\mathrm{d}v^2} \tag{8.3.30}$$

with:

$$\begin{aligned}
E&=\left(\frac{\partial}{\partial u}x\right)^2+\left(\frac{\partial}{\partial u}y\right)^2+\left(\frac{\partial}{\partial u}z\right)^2=(\partial_1 x)^2+(\partial_1 y)^2+(\partial_1 z)^2\\
G&=\left(\frac{\partial}{\partial v}x\right)^2+\left(\frac{\partial}{\partial v}y\right)^2+\left(\frac{\partial}{\partial v}z\right)^2=(\partial_2 x)^2+(\partial_2 y)^2+(\partial_2 z)^2\\
F&=\frac{\partial}{\partial u}x\frac{\partial}{\partial v}x+\frac{\partial}{\partial u}y\frac{\partial}{\partial v}y+\frac{\partial}{\partial u}z\frac{\partial}{\partial v}z=\partial_1 x\partial_2 x+\partial_1 y\partial_2 y+\partial_1 z\partial_2 z
\end{aligned} \tag{8.3.31}$$

Remarks

R1. The expression given above for the linear elements $\mathrm{d}s$ is named "quadratic fundamental form" of the surface considered. The coefficients E,F,G are functions of curvilinear coordinates. Generally this surface, considered a two-dimensional space, will be an example of Riemann space, for arbitrary curvilinear coordinates.

R2. The different Riemann spaces are what we name in general form (because there is not only Riemannian spaces of constant curvature) a "variety" equipped with a Riemannian metric. A variety may be defined (not formally), for example, by a set of points into an existing space. Generally a surface gives the idea of a two-dimensional variety. The sphere and the torus are two-dimensional varieties without borders. A cylinder of revolution, a hyperbolic paraboloid are two-dimensional open varieties with borders to infinity. But we can also consider abstract varieties. This is the case for example of a configuration space. This is then an n-dimensional space represented by a set q^i (or denoted by u^i) of generalized coordinates (see the introduction to the Lagrangian formalism in the section of Analytical Mechanics page 3155), the latter can have values in a finite domain or not.

We can now define in a little better way what is a Riemann space.

Definition (#8.3.349): A "Riemann space" is a variety to which we attached a metric. This means that in every part of the variety analytically represented by a coordinate system u^i, we gave ourselves a quadratic differential form:

$$\mathrm{d}s^2=g_{ij}\mathrm{d}u^i\mathrm{d}u^j \tag{8.3.32}$$

which is the metric of space.

The coefficients g_{ij} are not entirely arbitrary and should verify, as we have shown in the section of Tensor Calculus, the following conditions:

C1. The components are symmetric as $g_{ij}=g_{ji}$

C2. The determinant of the matrix of g_{ij} is not zero

C3. The differential form of the linear element $\mathrm{d}s^2$, and therefore the concept of distance defined by the g_{ij}, is invariant vis-a-vis any change of coordinates.

C4. All partial differential of second order of the g_{ij} exist and are continuous and therefore of class $\mathcal{C}^2$.

A Riemann space is a space of points, each being identified by a system of n coordinates u^i, with a metric such as the differential form of the linear element that satisfies the above conditions. This metric is therefore named "Riemannian metric".

Remarks

R1. If the metric is positive definite, that is to say, if $g_{ij}u^iu^j$ for any non-zero vector $\vec{v}$, we say that the space is "strictly Riemannian". In this case, the determinant of the matrix g_{ij} is strictly positive and all the eigenvalues of the matrix are strictly positive (see section Analytical Geometry page 2794).

R2. By definition, we say that a metric space is Euclidean when any fundamental tensor of this space may be reduced, by an appropriate change of coordinates, to a form such as (see section Vector Calculus page 1810) the canonical orthonormal basis. That is to say $g_{ij}=\delta_{ij}$.

R3. The definition of Riemannian spaces shows that Euclidean space is a very special case of these spaces. So there exists only one Euclidean space but we can create an infinite number of Riemannian spaces.

It is important to see that:

$$\mathrm{d}s^2=E\mathrm{d}u^2+2F\mathrm{d}u\mathrm{d}v+G\mathrm{d}v^2 \tag{8.3.33}$$

Can be rewritten as:

$$\frac{\mathrm{d}s^2}{\mathrm{d}t^2}=E\frac{\mathrm{d}u^2}{\mathrm{d}t^2}+2F\frac{\mathrm{d}u\mathrm{d}v}{\mathrm{d}t^2}+G\frac{\mathrm{d}v^2}{\mathrm{d}t^2}=E\left(\frac{\mathrm{d}u}{\mathrm{d}t}\right)^2+2F\frac{\mathrm{d}u}{\mathrm{d}t}\frac{\mathrm{d}v}{\mathrm{d}t}+G\left(\frac{\mathrm{d}v}{\mathrm{d}t}\right)^2 \tag{8.3.34}$$

that we denote by tradition:

$$\frac{\mathrm{d}s^2}{\mathrm{d}t^2}=E\dot{\mathrm{u}}^2+2F\dot{\mathrm{u}}\dot{\mathrm{v}}+G\dot{\mathrm{v}}^2 \tag{8.3.35}$$

Therefore:

$$\mathrm{d}s=\sqrt{E\dot{\mathrm{u}}^2+2F\dot{\mathrm{u}}\dot{\mathrm{v}}+G\dot{\mathrm{v}}^2}\mathrm{d}t \tag{8.3.36}$$

Hence the length of a curve on any differential surface:

$$\boxed{s(t_0,t_1)=\int\limits_{t_0}^{t_1}\sqrt{E\dot{\mathrm{u}}^2+2F\dot{\mathrm{u}}\dot{\mathrm{v}}+G\dot{\mathrm{v}}^2}\mathrm{d}t} \tag{8.3.37}$$

✍**Example:**

Let us consider the parametric equation of a special hyperbolic surface:

$$\Sigma(u,v)=\begin{pmatrix}u\\v\\uv\end{pmatrix},\ u,v\in\mathbb{R}^2 \tag{8.3.38}$$

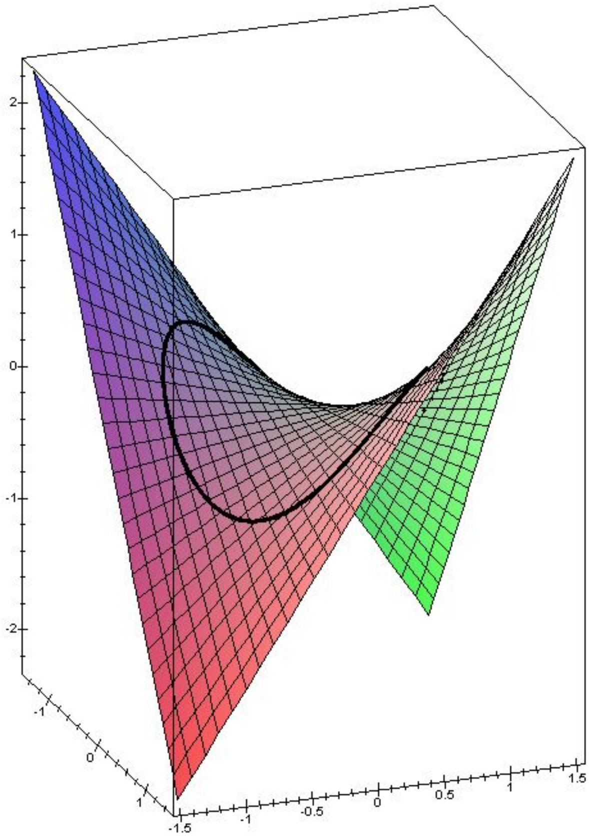
We take now the parametric equation of a circle of radius 1 on the plane:

$$\Gamma(u(t),v(t))=\begin{pmatrix}\cos(t)\\\sin(t)\end{pmatrix} \tag{8.3.39}$$

That is to say visually with Maple™ 4.00b:

```
>x:=u;y:=v;z:=u*v;
>with(plots):
>surface:=plot3d([x,y,z],u=-1.5..1.5,v=-1.5..1.5,grid=[30,30],
scaling=constrained,axes=boxed,style=PATCH):
>curve:=spacecurve([cos(t),sin(t),cos(t)*sin(t)],t=-4*Pi..4*Pi,
numpoints=1000,scaling=CONSTRAINED,orientation=[50,60],style=PATCH,
axes=NORMAL,color=black,thickness=3):
>display(surface,curve,orientation=[-20,70]);
```

Which gives:



Therefore:

$$\begin{aligned}
E&=(\partial_1 x)^2+(\partial_1 y)^2+(\partial_1 z)^2=1^2+0^2+v^2=1+v^2\\
G&=(\partial_2 x)^2+(\partial_2 y)^2+(\partial_2 z)^2=0^2+1^2+u^2=1+u^2\\
F&=\partial_1 x\partial_2 x+\partial_1 y\partial_2 y+\partial_1 z\partial_2 z=0^2+0^2+uv=uv
\end{aligned}\tag{8.3.40}$$

Then we have:

$$s(t_0,t_1)=\int\limits_{t_0}^{t^1}\sqrt{(1+v^2)\dot{\mathrm{u}}^2+2uv\dot{\mathrm{u}}\dot{\mathrm{v}}+(1+u^2)\dot{\mathrm{v}}^2}\mathrm{d}t\tag{8.3.41}$$

And we want to calculate the perimeter of the circle on the surface. Therefore:

$$\begin{aligned}
&s(0,2\pi)=\int\limits_0^{2\pi}\sqrt{(1+v^2)\dot{\mathrm{u}}^2+2uv\dot{\mathrm{u}}\dot{\mathrm{v}}+(1+u^2)\dot{\mathrm{v}}^2}\mathrm{d}t\\
&=\int\limits_0^{2\pi}\sqrt{(1+\cos^2(t))\dot{\mathrm{u}}^2+2\cos(t)\sin(t)\dot{\mathrm{u}}\dot{\mathrm{v}}+(1+\sin^2(t))\dot{\mathrm{v}}^2}\mathrm{d}t\\
&=\int\limits_0^{2\pi}\sqrt{(1+\sin^2(t))(-\sin(t))^2+2\cos(t)\sin(t)(-\sin(t))(\cos(t))+(1+\cos^2(t))(\cos(t))^2}\mathrm{d}t\\
&=\int\limits_0^{2\pi}\sqrt{(1+\sin^2(t))(-\sin(t))^2-2\cos^2(t)\sin^2(t)+(1+\cos^2(t))(\cos(t))^2}\mathrm{d}t\\
&=\int\limits_0^{2\pi}\sqrt{1+2\cos^2(t)\sin^2(t)+\sin^4(t)+\cos^4(t)}\mathrm{d}t\\
&=\int\limits_0^{2\pi}\sqrt{1+(\cos^2(t)-\sin^2(t))^2}\mathrm{d}t\\
&=\int\limits_0^{2\pi}\sqrt{1+\cos^2(2t)}\mathrm{d}t
\end{aligned}\tag{8.3.42}$$

We make a change of variable $\tau=2t$, and therefore:

$$\mathrm{d}\tau=2\mathrm{d}t\qquad 2\pi\rightarrow 2\pi\qquad 0\rightarrow 0\tag{8.3.43}$$

and therefore:

$$s(0,2\pi)=\frac{1}{2}\int\limits_0^{4\pi}\sqrt{1+\cos^2(\tau)}\mathrm{d}\tau\tag{8.3.44}$$

As the integrand is even:

$$s(0,2\pi)=\int\limits_0^{2\pi}\sqrt{1+\cos^2(\tau)}\mathrm{d}\tau \tag{8.3.45}$$

We have then:

$$\int\limits_0^{2\pi}\sqrt{1+\cos^2(\tau)}\mathrm{d}\tau=4\int_0^{\pi/2}\sqrt{1+\cos^2(\tau)}\mathrm{d}\tau=4\int\limits_0^{\pi/2}\sqrt{2-\sin^2(\tau)}\mathrm{d}x \tag{8.3.46}$$

$$=4\sqrt{2}\int\limits_0^{\pi/2}\sqrt{1-\frac{\sin^2(\tau)}{2}}\mathrm{d}\tau=4\sqrt{2}E\left(\frac{1}{\sqrt{2}}\right) \tag{8.3.47}$$

With:

$$\boxed{E(k)=\int\limits_0^{\pi/2}\sqrt{1-k^2\sin^2(\tau)}\mathrm{d}x} \tag{8.3.48}$$

and is referred to as the "complete elliptic integral of second kind" (see section Differential and Integral Calculus page 1599). This integral cannot be formally calculated. But a numerical integration gives:

$$s(0,2\pi)=\int\limits_0^{2\pi}\sqrt{1+\cos^2(\tau)}\mathrm{d}\tau\cong 7.6404 \tag{8.3.49}$$

8.4. Projective Geometry

SINCE Chasles and this until the years 1930s (holocene calendar), Projective Geometry was often synonymous of "higher geometry." It was opposed to Euclidean Geometry: that was said to be elementary and analytical. At the time of Monge, Carnot and von Staudt, we also spoke of "geometry of position" or "geometry of situation". These geometries study figures at the point of view of their respective positions and of their invariant properties which bind them in a geometric transformation (rotation, symmetry, scaling, etc.), homographic in particular. Besides the harmonic division, basic concept, it uses the famous anharmonic ratio (cross ratio), the inverse, the involution the transformation by reciprocal polar, stereographic projection[5], the correlation, the homology, the duality, the conical, etc. (see later in this text for the definitions).

Definition (#8.4.350): "Projective geometry" is a topic of mathematics. It is the study of geometric properties that are invariant with respect to projective transformations. This means that, compared to elementary geometry, projective geometry has a different setting, "projective space", and a selective set of basic geometric concepts.

Project Geometry is quite abstract apart from some general and basic principles outlined below (undergraduate level). It is therefore relatively difficult to understand and requires before study it: a good knowledge of elementary geometry even in space, a perfect mastery of three-dimensional space in the observation-representation-interpretation cycle, to master also complex analysis for advanced topics. This will led us to introduce some concepts that do not normally have their place in this section, but that we think, can greatly help the reader to understand this branch of mathematics.

In a first place, we will discuss the basic concepts of perspective with a particular focus on the concept of "projective" representation (there are other empirical perspective methods: cavalier, cabinet, isometric, military, ... but these latter don't have mathematical or real meaning even if they represent quite properly volumetric objects). Then we will study the mathematical representations of some three-dimensional objects with some computer application to finally go study "hard" and "pure" projective geometry.

Definition (#8.4.351): "perspective" refers to a way of seeing, analyzing, or interpreting something, often influenced by cultural, historical, or personal contexts. In visual arts, it is a technique for representing depth and three-dimensionality on a flat surface. In social science or philosophy, it can refer to a point of view or conceptual position on a particular subject.

Remark

The "descriptive geometry" is a rigorous artistic form of projective geometry but not a formal on (in the sense that it is not mathematically formalized... at least as far as we know...).

---

[5] ie: projection on a plane

8.4.1 Conical Perspective (Central Perspective)

One problem with the study of three-dimensional volumes and their representation is the concept of "perspective". Indeed, human beings can not see the 3 dimensions of an object, it is the brain that interprets the shadows and reflections of an object so that we can interpret it as having a volume (there are optical illusions that go in this direction ...: the "trompe l'oeil").

Here is an animated example of one of the most famous optical illusion, named the Shepard tabletop illusion, that shows that we should, statistically speaking, not trust our intuitions too much...:

The animation above will run for people having a PDF reader with Adobe Flash player installed and activated (otherwise see here: `https://vimeo.com/575741013`).

We will focus in the following paragraphs on the "conical perspective", also named "central perspective" or "linear perspective". Linear perspective is thought to have been devised about 11415 (holocene calendar) by Italian Renaissance architect Filippo Brunelleschi and later documented by architect and writer Leon Battista Alberti in 11435 (holocene calendar).

Remark

In the field of projective geometry we are not talking about "conical perspective" but "conical projection".

Definition (#8.4.352): The "conical perspective" or "perspective projection" (to not be confused with the "conical projection"!!!!!) is by construction the closest representation of our human visual perceptions, it allows especially to see a sphere as a circle as the human vision is based on a visual cone that when looking to a sphere is equivalent to see a circle as illustrated below:

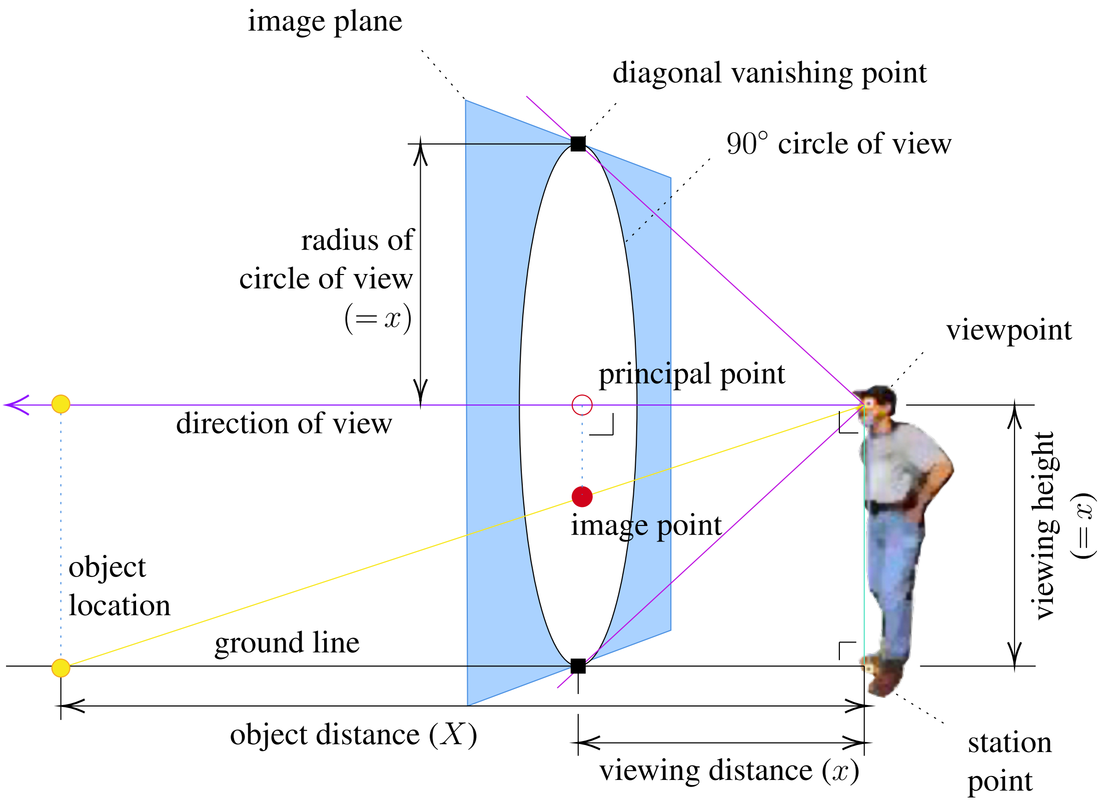

image plane
diagonal vanishing point
90° circle of view
radius of circle of view $(= x)$
viewpoint
principal point
direction of view
image point
object location
ground line
viewing height $(= x)$
object distance (X)
viewing distance (x)
station point

Figure 8.101: **Visual cone and corresponding projection circle**

Remark

The conical perspective is that of Renaissance painters. It is also the one that appears on photos.

The difficulty of the representation in perspective is to translate it in a plane (for example that of the paper or the computer screen as our eyes makes a projection of a 3D world in a 2D image in our brain) a construction (object) that is defined - fairly simply, by the way - in space using mathematical tools.

A conical perspective of the conventional 3-dimensional space is a projective transformation that sends all the points of space on the same plane of this space. It requires the information of a point O (equivalent to the position of the observer's eye) and a projection plane named the "table" or "Dürer glass" (the equivalent of our retina) as referring to a quite old copy painting method:

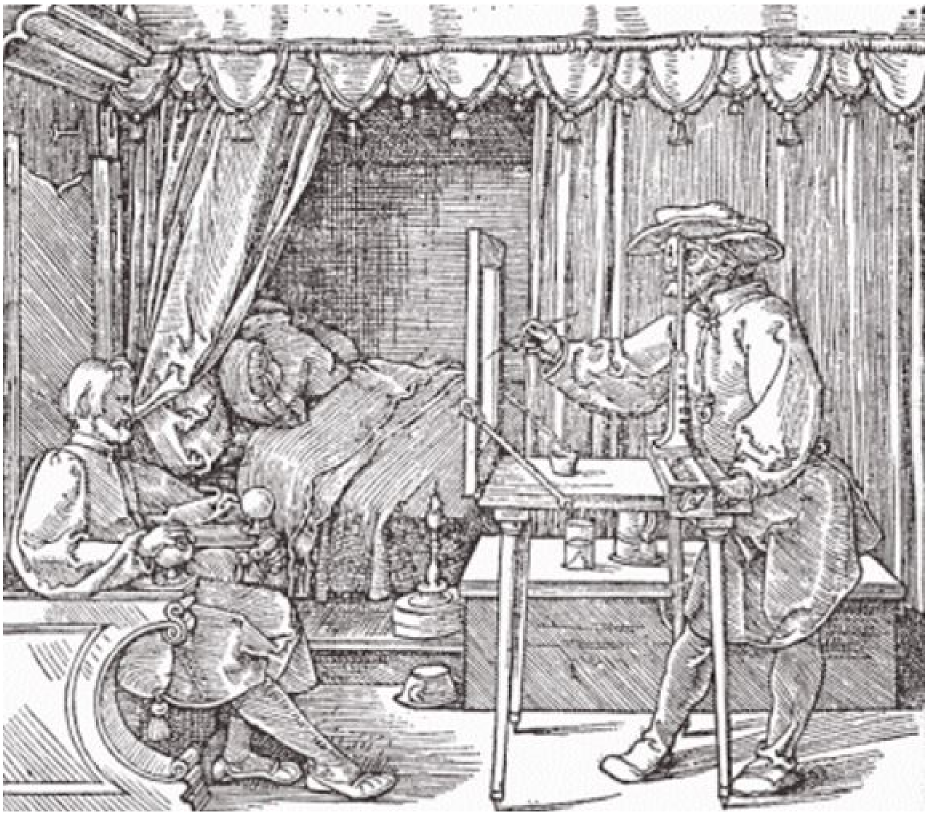

Figure 8.102: **Origin of Durer glass method illustration**

We will see during the theoretical mathematical developments that unlike affine projections (see the following subsection), the conical projection does not retain the barycenter (therefore the ratios of lengths on a given straight line) but it conserve the alignment and cross ratio.

When we speak of conical perspective, we use a few special planes and straight lines in three-dimensional space (see figure below).

Definitions (#8.4.353):

D1. The "picture plane" or "Dürer glass", denoted T, is the plane on which we are drawing (projection plane).

D2. The "ground plane", denoted S, is a fixed plane, perpendicular to the picture plane T.

D3. The "point of view" (or "center of projection"), denoted O, is a point out of T and of S: this is the point where we will have to place the eye for the drawing on the picture plane T coincides with the real image.

D4. The "horizon plane" denoted H, is the plane parallel to the ground plane S passing through the point of view point O.

D5. The "horizon line", denoted h, is the intersection of the horizon plane H and the picture plane T.

D6. The "Earth line", denoted EL, is the intersection of the ground plane S plan and of the picture plane T.

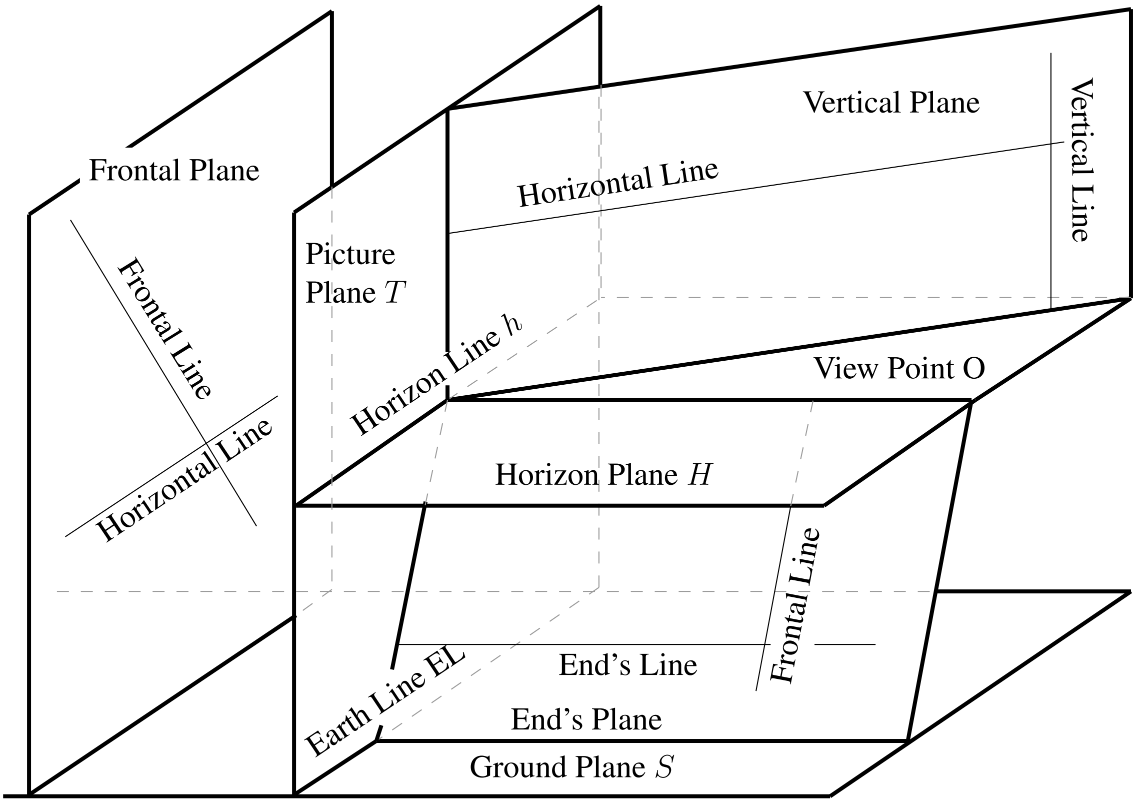
D7. A plane or a straight line parallel to the ground plane S that are named "horizontal".

D8. A plane or a straight line perpendicular to the ground plane S that are named "vertical".

D9. A plane or a straight line parallel to the picture plane T that are named "front".

D10. A plane or a straight line perpendicular to the picture plane T that are named "end".

Here is a diagram showing these different concepts:



Frontal Plane
Frontal Line
Horizontal Line

End's Plane
Ground Plane S

Figure 8.103: **Definition of the planes and lines of projective geometry**

8.4.1.1 Images of Points

Any volumetric object (which can only be determined by touching or at the level of mathematical abstraction) composed by a set of points M, is for our brain, the image of a plane projection m whose support is a surface in the space between the observed object and our eye.

In mathematics, this surface, we know, named the "table" is defined in its central view by the horizon line (where are located the vanishing points) and a physical repository so named the Earth line (see figure below where the observer is at a higher point than the observed object):

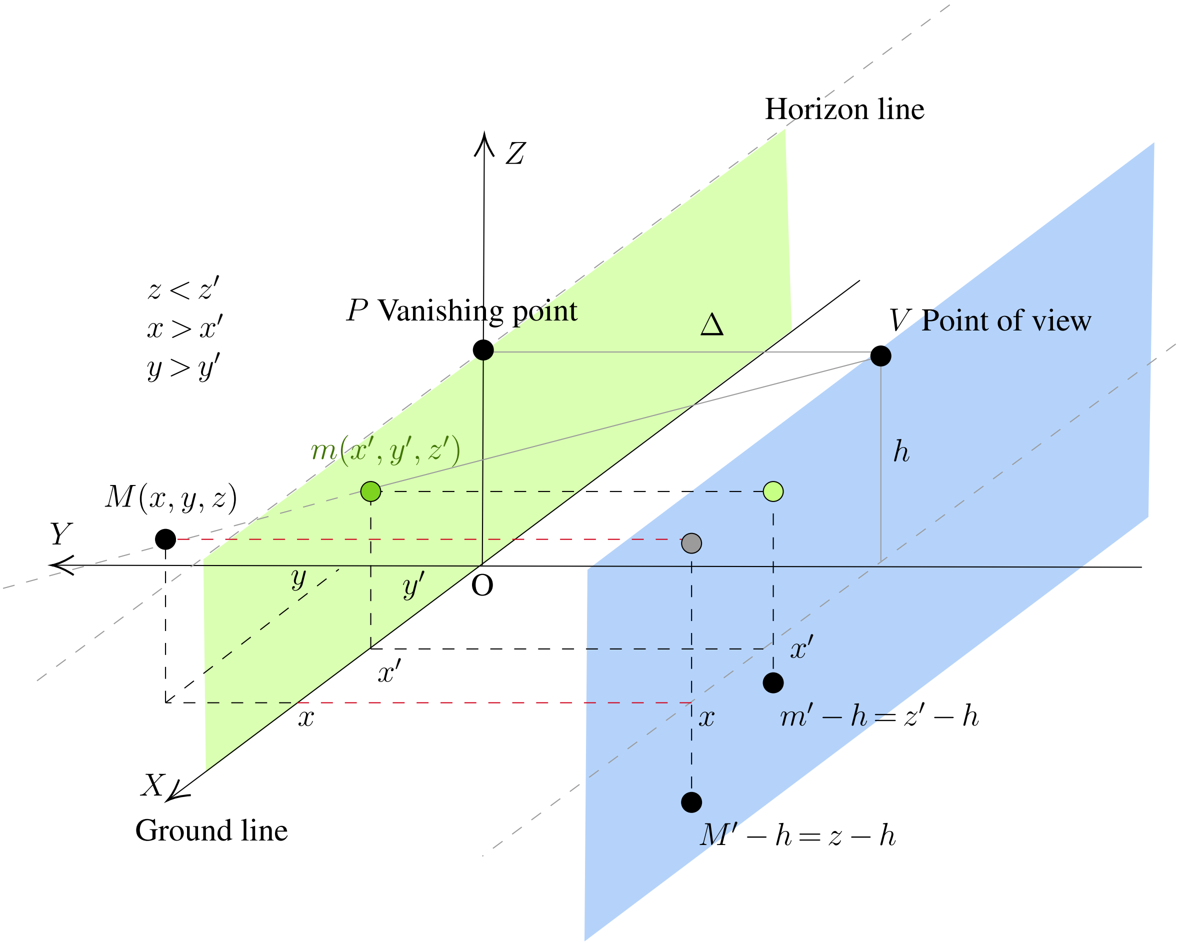

Figure 8.104: Example of what is a "table" in projective geometry

The height between the ground line and the point view is named the "horizon height" and is denoted by h.

The objective from this figure is to mathematically determine a representation of a solid object on a surface (on a plane in a simple case, otherwise any) by knowing the equation of the line between point M (point of the observed object) and the point V (point of view) in the purpose to determine the coordinates of intersection between this line and the table.

We can from the above diagram draw the following relations using the Thales theorem (see section Euclidean Geometry page 2610) in the different triangles:

$$\frac{x}{x'}=\frac{z-h}{z'-h}=\frac{y+\Delta}{y'+\Delta} \tag{8.4.1}$$

with $\Delta \geq 0$.

If we put $y'=0$, according to what shows the figure above, the coordinates of m become:

$$x'=x\frac{\Delta}{y+\Delta} \tag{8.4.2}$$

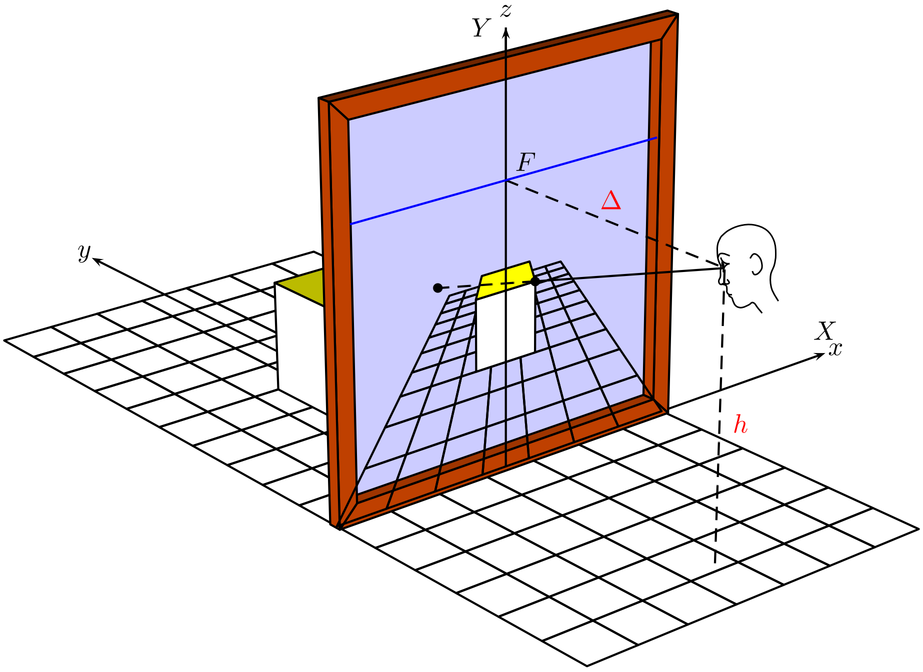
and:

$$z'=h+(z-h)\frac{\Delta}{y+\Delta}=\frac{hy+\Delta z}{y+\Delta} \tag{8.4.3}$$

Often summarized as the "homographic transformations" (we will come back on the latter further below and prove some of their properties):

$$\boxed{\begin{aligned} X&=\frac{x\Delta}{y+\Delta}\\ Y&=\frac{hy+\Delta z}{y+\Delta}\end{aligned}} \tag{8.4.4}$$

and illustrated by:



Notice that whatever the values of $h\geq 0$, $z\geq 0$ or $\Delta\geq 0$ we always have $z'\geq 0$. Hence in linear perspective an object can never disappear by the bottom!

From these relations, the problem of a plane representation of a volumetric shape completely solved, since we can always project a point (or the distance between two points) on a table from the coordinates of the original.

The term Δ is commonly named the "focal length" from the point of view to the table and optical specialists usually denote it with the letter f.

To understand this result, we can put ourselves in the context of a two-dimensional study where the observer is at the height of the ground line ($h=0$) and arranged to represent a person looking at the table (comparable to a TV screen, computer screen or other screen) in which we ask the conventional x and y axes in the screen plane and the z axes perpendicular to it (thus relative to the last figure, Y becomes Z and vice versa).

Thus, the above relation of the ratios:

$$\frac{x}{x'}=\frac{z-h}{z'-h}=\frac{y+\Delta}{y'+\Delta} \quad (8.4.5)$$

becomes with this change of axis:

$$\frac{x}{x'}=\frac{y-h}{y'-h}=\frac{z+\Delta}{z'+\Delta} \quad (8.4.6)$$

and as $h=0$ (which is often the case in front of screens):

$$y'=\frac{y(z'+\Delta)}{z+\Delta} \quad (8.4.7)$$

If the table is placed on the axis of reference (the projection table is assimilated to the screen), then we have $z'=0$ which gives us:

$$y'=\frac{y\Delta}{z+\Delta} \quad (8.4.8)$$

and by proceeding in the same way:

$$x'=\frac{x\Delta}{z+\Delta} \quad (8.4.9)$$

Remark

The last two relations are those that we use to make 3D animations programmed in the Macromedia Flash 6.0 (see example further below) or in Javascript (see example also further below) on in any other programming language.

We see with the last two relations an identical term:

$$\boxed{P=\frac{\Delta}{z+\Delta}} \quad (8.4.10)$$

This term corresponds to the "depth" of the perspective.

In some textbooks, this depth is denoted by (simply factorization):

$$P=\frac{1}{1+\dfrac{z}{\Delta}} \quad (8.4.11)$$

If we consider two points (x_1,x_2 or y_1,y_2) visible from the surface of a volume seen by an observer and their respective distance Δx or Δy, these quantities are preserved if the two points coincide in the plane of the table because we have then:

$$P=1 \tag{8.4.12}$$

as $z=0,\forall\Delta$.

It is interesting to study what should be the value of the focal length for $z\neq 0$ to have $\Delta x'=\Delta x$ or $\Delta y'=\Delta y$. Thus, if we take the limit:

$$\lim_{\Delta\rightarrow+\infty} P=\frac{\Delta}{z+\Delta} \tag{8.4.13}$$

by applying l'Hôpital's rule (derivative of the numerator and denominator as seen in the section of Differential and Integral Calculus page 1461) and remembering that z is fixed, then:

$$\lim_{\Delta\rightarrow+\infty} P=\frac{\Delta}{z+\Delta}=\frac{\dfrac{\mathrm{d}}{\mathrm{d}\Delta}\Delta}{\dfrac{\mathrm{d}}{\mathrm{d}\Delta}(1+\Delta)}=\frac{1}{0+1}=1 \tag{8.4.14}$$

From this result we can conclude the following:

For any real distance between two points that do not coincide in the table but located in a same plane have an equal projection distance, it is necessary that the equations of the two lines that determine their intersection with table are parallel. This implies, since the observer is a convergent point, that we have to take away the observer to an infinite distance from the plane to keep the quantities projected on the table: this is the "orthogonal parallel projection" also sometimes named "orthographic parallel projection".

A very good example to see these results is to program in pseudo-3D on a computer.

✍**Example:**

There are many ways to do pseudo 3D with computers. The best known are technically OpenGL or DirectX and C++ but are not very easy to introduce ... so we'll see how to turn a pseudo-sphere in the projective space with Macromedia Flash 6.0 in order to show how apply the different theoretical elements presented above, but also to show that these are not the only tools available.

For this purpose, open the Macromedia Flash 6.0 software and save the new animation with the name *Circle.fla*:

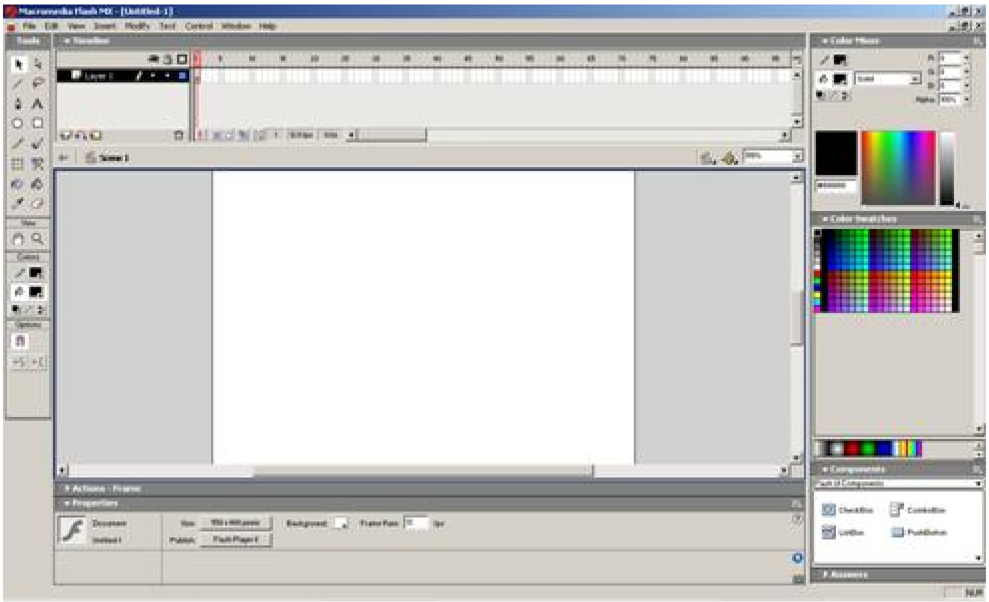


Figure 8.105: **Macromedia Flash 6.0 GUI**

With the **Circle** tool in the **Drawing** toolbar, draw a respectable size disc in the animation area:

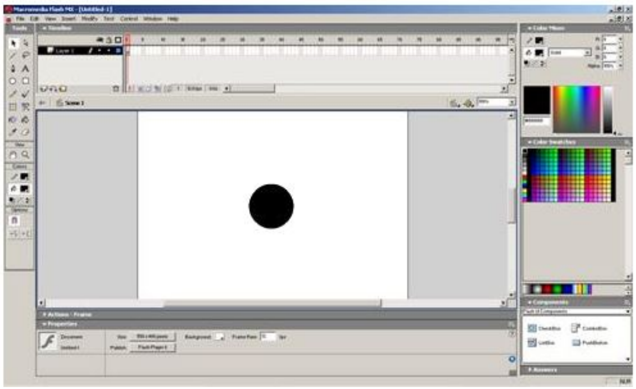

Figure 8.106: **Disc in the animation area**

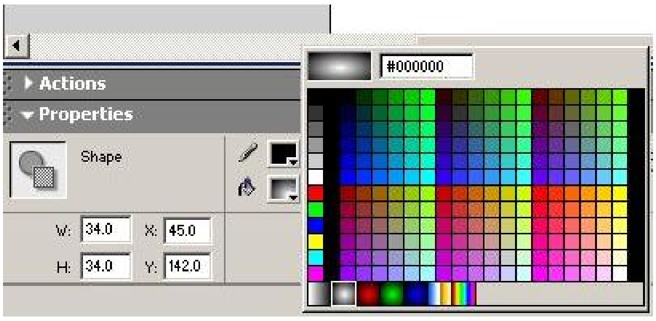
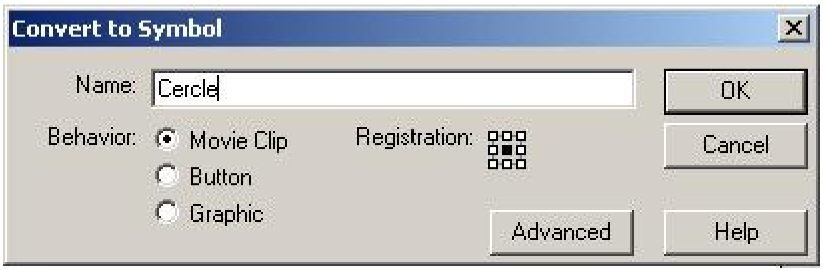
After having selected the circle with the **Fill** tool choose a *Radial Gradient*:



W: 34.0 X: 45.0
H: 34.0 Y: 142.0
#000000

Figure 8.107: **Color palette to fill-in the circle**

Right-click on the circle and choose the option **Convert to Symbol** and enter the information as presented below:



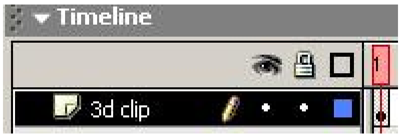
Convert to Symbol
OK
Cancel
Advanced
Help
Registration:
Button
Graphic

Name: Cercle

Behavior: ● Movie Clip

Figure 8.108: **Conversion dialogue box from of Object to Symbol**

Rename the layer where lies your animation clip with the name *3d clip*:

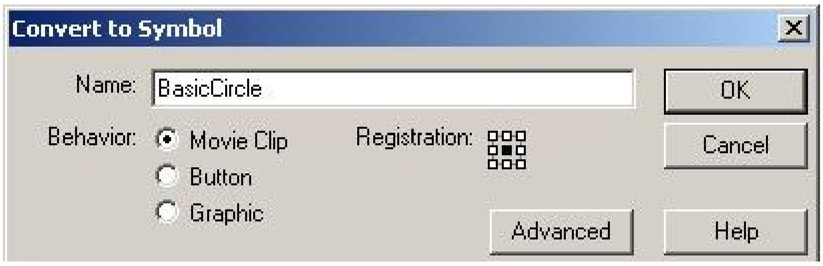


3d clip

Figure 8.109: **Renaming the animation layer**

Afterwards double-click on your circle to enter your animation Clip.

There select the circle again, right-click it and select **Convert to Symbol**:

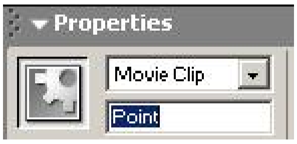


Convert to Symbol
OK
Cancel
Advanced
Help
Registration:
Button
Graphic

Name: BasicCircle

Behavior: ● Movie Clip

Then, in the properties of the circle enter the name *Point*:



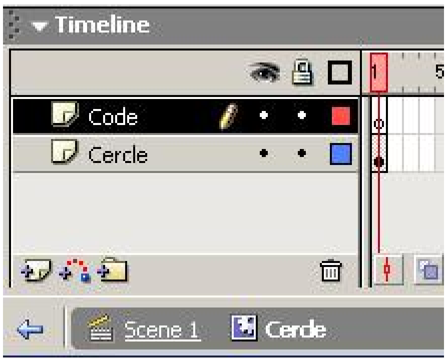
Properties

Movie Clip

Point

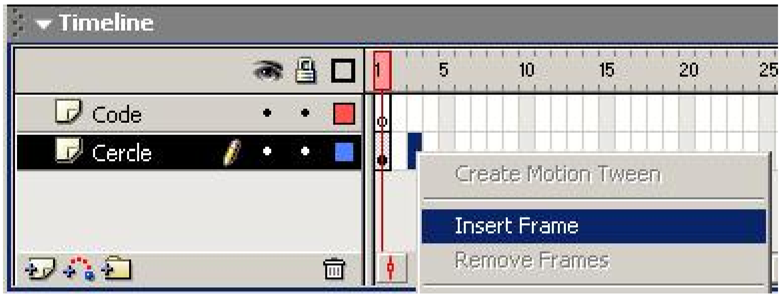
Now, in the animation Clip named *Cercle*, we will insert three frames: the first to define the mathematical functions necessary for recalculating the variables, the second calling functions, the third that allows us to loop and go the second frame indefinitely.

To make things in an almost clean way, we will create a second layer (by renaming the first one that contains our circle with the name *Cercle*) that we will rename *Code*:



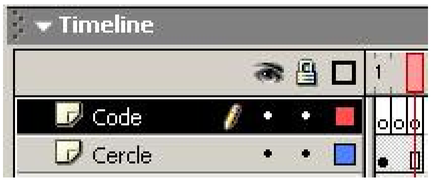
Timeline
Code
Cercle
Scene 1
Cercle

Do a right-click on the third image of the layer containing our circle:



Timeline
Code
Cercle
Create Motion Tween
Insert Frame
Remove Frames

and choose the option **Insert Frame** and for the layer *Code* made almost the same, but by choosing **Insert Key Frame**. You should then get the following display:



Timeline
Code
Cercle

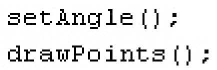
Then by selecting the first image of the layer *Code* activates the display of the Action to insert the following code:

```
Radius = 100;
degrees = 0;
Xcenter=0;
Ycenter=0;
speed=2;

function setAngle () {
     Angle = degrees * (Math.PI / 180);
     degrees = degrees + speed;
}

function drawPoints () {
     Point._x = Radius * Math.cos(Angle)+Xcenter;
     Point._y = Radius * Math.sin(Angle)+Ycenter;
}
```

Repeat the same with the second image of the layer *Code*, but putting this time inside it:



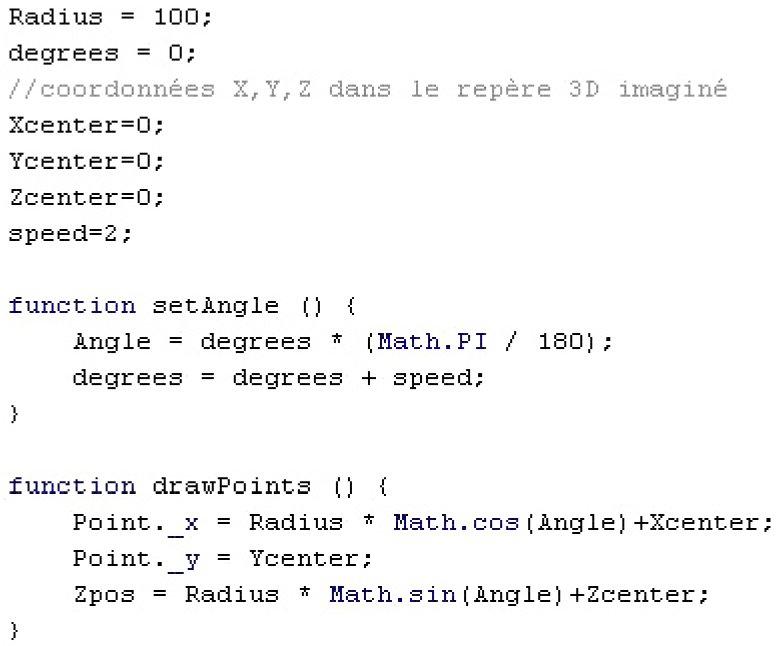
```
setAngle();
drawPoints();
```

and finally doing the same with the third image of the same layer, but by putting inside it:

```
gotoAndPlay(2);
```

We then get the following animated result (the animation is only visible on a PDF reader with Adobe Flash installed and activated otherwise go see here https://vimeo.com/578782166):

We will now make appear the z-axis by fixing y (and therefore by moving z). Obviously, we will not see anything happen with regard to z until we define the homographic projection and this because a computer is unable to show basically the concept of depth... The code is then written:



```
Radius = 100;
degrees = 0;
//coordonnées X,Y,Z dans le repère 3D imaginé
Xcenter=0;
Ycenter=0;
Zcenter=0;
speed=2;

function setAngle () {
    Angle = degrees * (Math.PI / 180);
    degrees = degrees + speed;
}

function drawPoints () {
    Point._x = Radius * Math.cos(Angle)+Xcenter;
    Point._y = Ycenter;
    Zpos = Radius * Math.sin(Angle)+Zcenter;
}
```

The calculation of `Zpos` will enable us further below to calculate the depth of the movement of the object along the z-axis and this is where the homographic projection will play a role.

We then get a pseudo-sphere which rotates around an axis in a plane perpendicular to the screen. This is why we see the pseudo-sphere make left / right trips (the concept of distance is not yet present because of a lack of presence of the depth factor):

The animation above will run for people having a PDF reader with Adobe Flash player installed and activated (otherwise see here: https://vimeo.com/578782447).

Now we will use the relations:

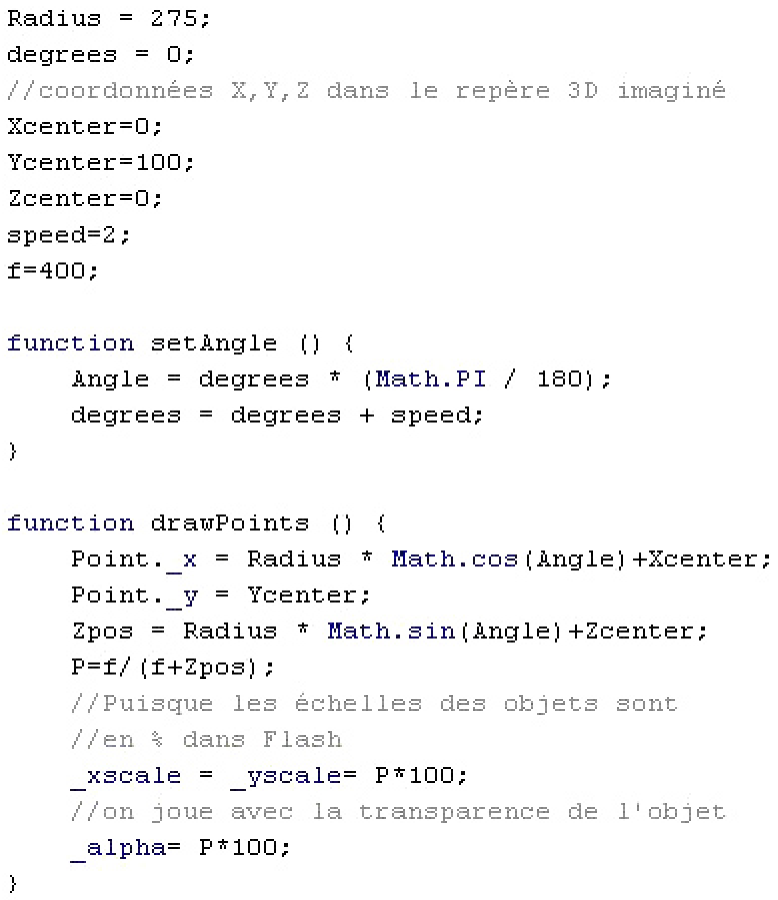
$$\begin{aligned}x'(z)&=xP=x\frac{f}{z+f}\\ y'(z)&=yP=y\frac{f}{z+f}\end{aligned}\tag{8.4.15}$$

proved earlier. If we seek to represent the depth of any point of the projection table, it is the distance ratio between two points in the table that will interest us to determine the scaling factor:

$$\begin{aligned}\frac{x'_2(z)-x'_1(z)}{x_2-x_1}\%&=\frac{f}{z+f}\cdot 100=P\cdot 100\\ \frac{y'_2(z)-y'_1(z)}{y_2-y_1}\%&=\frac{f}{z+f}\cdot 100=P\cdot 100\end{aligned}\tag{8.4.16}$$

We will have therefore to apply this result as defining the scale of the projection table.

We then have the following code where the depth P plays on the height and width of the animated surface of the instance *Point* of our pseudo-sphere:



```
Radius = 275;
degrees = 0;
//coordonnées X,Y,Z dans le repère 3D imaginé
Xcenter=0;
Ycenter=100;
Zcenter=0;
speed=2;
f=400;

function setAngle () {
    Angle = degrees * (Math.PI / 180);
    degrees = degrees + speed;
}

function drawPoints () {
    Point._x = Radius * Math.cos(Angle)+Xcenter;
    Point._y = Ycenter;
    Zpos = Radius * Math.sin(Angle)+Zcenter;
    P=f/(f+Zpos);
    //Puisque les échelles des objets sont
    //en % dans Flash
    _xscale = _yscale= P*100;
    //on joue avec la transparence de l'objet
    _alpha= P*100;
}
```

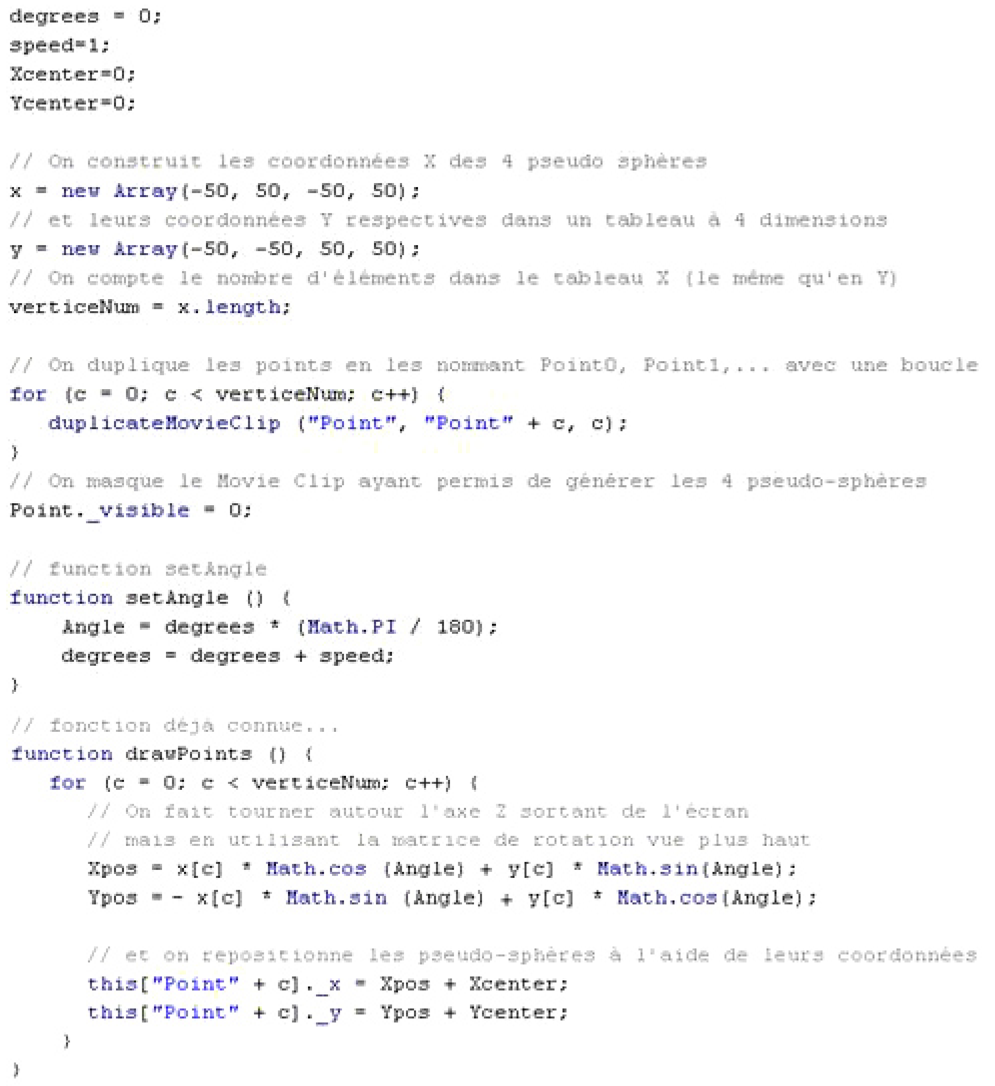
Which gives us:

and obviously it works regardless of the parametric equation of the path followed! We can then copy this instance animation, change the height, the starting angle for the get the 4 vertices of a cube rotating in space.

The animation above will run for people having a PDF reader with Adobe Flash player installed and activated (otherwise see here: `https://vimeo.com/578783079`).

This is the next step:

Indeed, let us change our code as shown below for 4 pseudo-spheres rotating around an imaginary z-axis going out of the screen (we use the rotation matrices proved in the section of Euclidean Geometry) and sorry for the comments in French as I did first the code for french readers:



```
degrees = 0;
speed=1;
Xcenter=0;
Ycenter=0;

// On construit les coordonnées X des 4 pseudo sphères
x = new Array(-50, 50, -50, 50);
// et leurs coordonnées Y respectives dans un tableau à 4 dimensions
y = new Array(-50, -50, 50, 50);
// On compte le nombre d'éléments dans le tableau X (le même qu'en Y)
verticeNum = x.length;

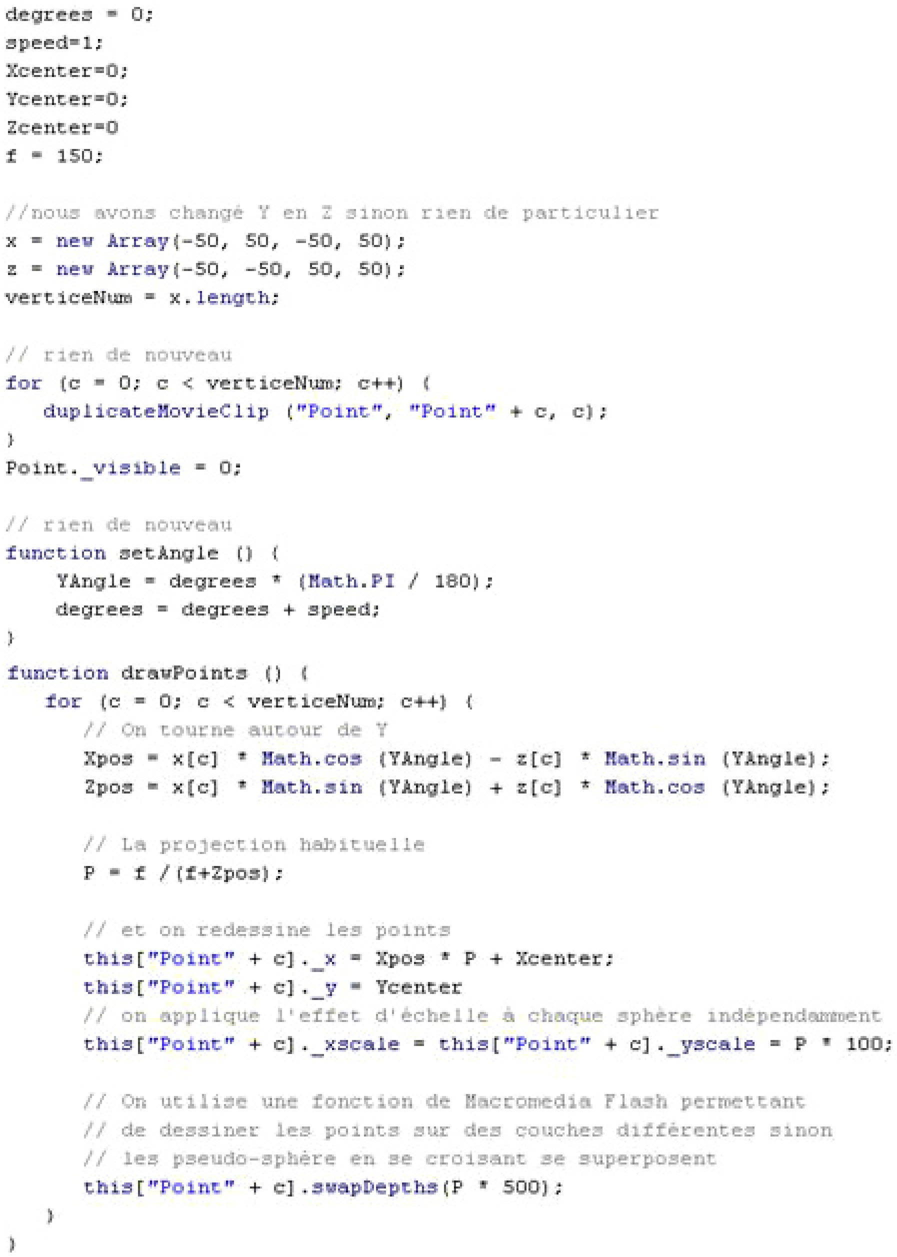
// On duplique les points en les nommant Point0, Point1,... avec une boucle
for (c = 0; c < verticeNum; c++) {
   duplicateMovieClip ("Point", "Point" + c, c);
}
// On masque le Movie Clip ayant permis de générer les 4 pseudo-sphères
Point._visible = 0;

// function setAngle
function setAngle () {
    Angle = degrees * (Math.PI / 180);
    degrees = degrees + speed;
}
// fonction déjà connue...
function drawPoints () {
   for (c = 0; c < verticeNum; c++) {
      // On fait tourner autour l'axe Z sortant de l'écran
      // mais en utilisant la matrice de rotation vue plus haut
      Xpos = x[c] * Math.cos (Angle) + y[c] * Math.sin(Angle);
      Ypos = - x[c] * Math.sin (Angle) + y[c] * Math.cos(Angle);

      // et on repositionne les pseudo-sphères à l'aide de leurs coordonnées
      this["Point" + c]._x = Xpos + Xcenter;
      this["Point" + c]._y = Ypos + Ycenter;
    }
}
```

This gives us ... four charming pseudo-spheres turning around a common center (the animation below will run for people having a PDF reader with Adobe Flash player installed and activated otherwise see here: https://vimeo.com/578783905):

Now we reverse y and z again and apply the homographic projection:



```
degrees = 0;
speed=1;
Xcenter=0;
Ycenter=0;
Zcenter=0
f = 150;

//nous avons changé Y en Z sinon rien de particulier
x = new Array(-50, 50, -50, 50);
z = new Array(-50, -50, 50, 50);
verticeNum = x.length;

// rien de nouveau
for (c = 0; c < verticeNum; c++) {
   duplicateMovieClip ("Point", "Point" + c, c);
}
Point._visible = 0;

// rien de nouveau
function setAngle () {
    YAngle = degrees * (Math.PI / 180);
    degrees = degrees + speed;
}
function drawPoints () {
   for (c = 0; c < verticeNum; c++) {
      // On tourne autour de Y
      Xpos = x[c] * Math.cos (YAngle) - z[c] * Math.sin (YAngle);
      Zpos = x[c] * Math.sin (YAngle) + z[c] * Math.cos (YAngle);

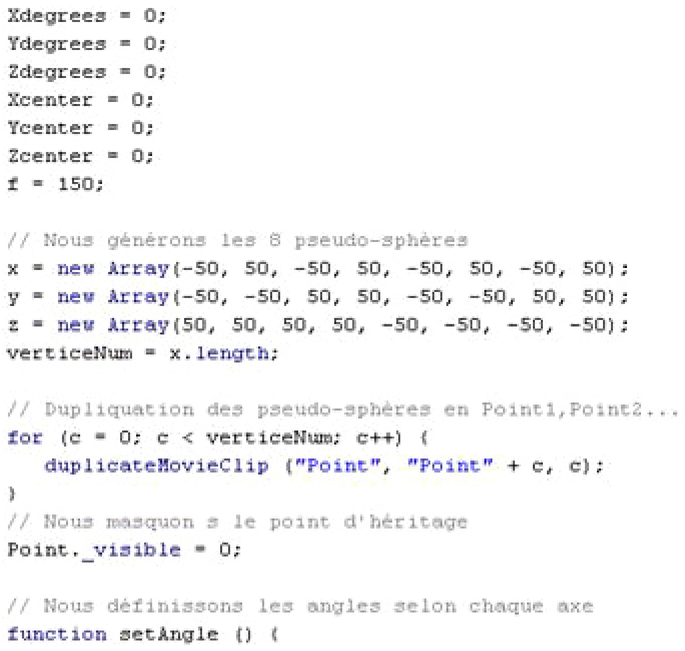
      // La projection habituelle
      P = f /(f+Zpos);

      // et on redessine les points
      this["Point" + c]._x = Xpos * P + Xcenter;
      this["Point" + c]._y = Ycenter
      // on applique l'effet d'échelle à chaque sphère indépendamment
      this["Point" + c]._xscale = this["Point" + c]._yscale = P * 100;

      // On utilise une fonction de Macromedia Flash permettant
      // de dessiner les points sur des couches différentes sinon
      // les pseudo-sphère en se croisant se superposent
      this["Point" + c].swapDepths(P * 500);
   }
}
```

and we get (the animation below will run for people having a PDF reader with Adobe Flash player installed and activated otherwise see here: https://vimeo.com/578784812):

For the remaining part, we will generate 8 pseudo-sphere and instead to turn them always about the same axis, we will rotate around three axes x, y or z using the variables `XAngle`, `YAngle` or `ZAngle` and rotation matrices about each of these respective axes:

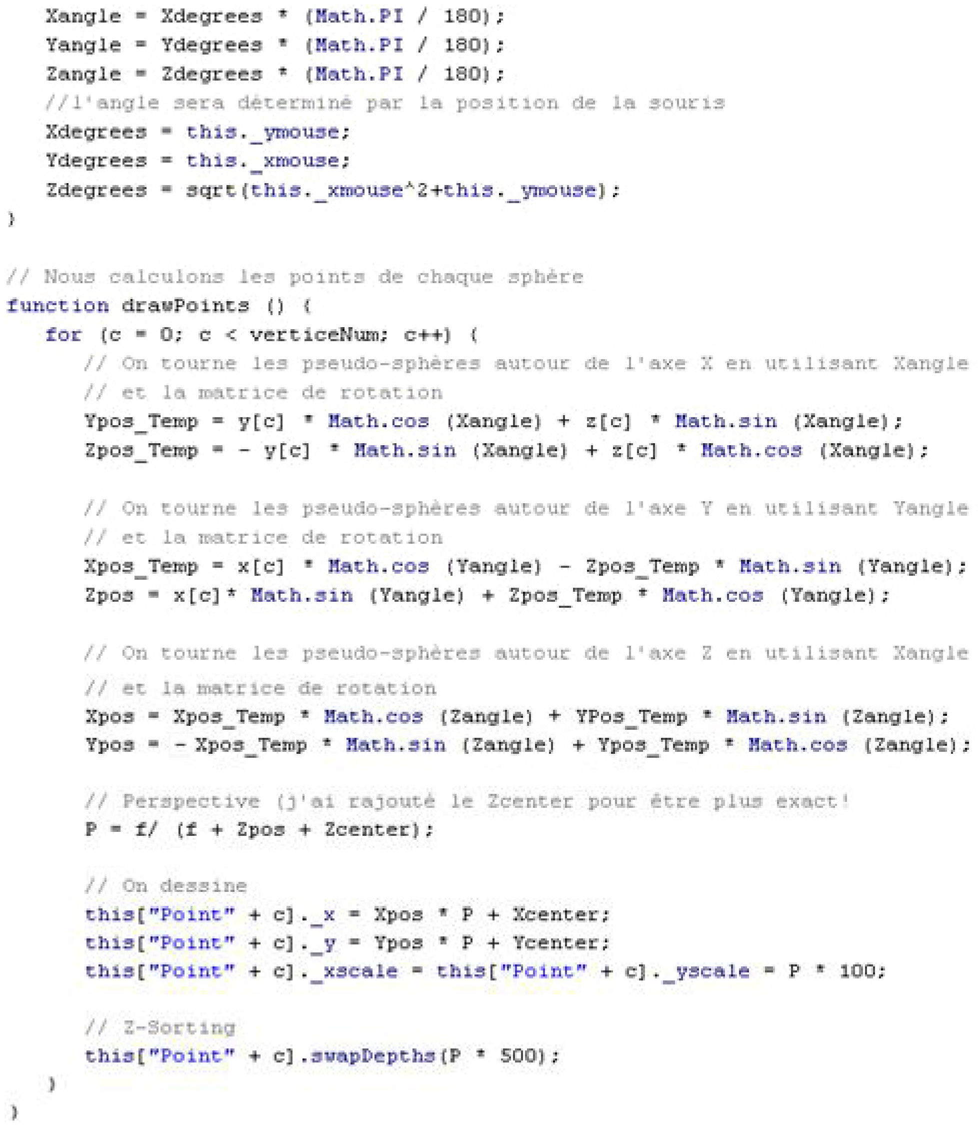


```
Xdegrees = 0;
Ydegrees = 0;
Zdegrees = 0;
Xcenter = 0;
Ycenter = 0;
Zcenter = 0;
f = 150;

// Nous générons les 8 pseudo-sphères
x = new Array(-50, 50, -50, 50, -50, 50, -50, 50);
y = new Array(-50, -50, 50, 50, -50, -50, 50, 50);
z = new Array(50, 50, 50, 50, -50, -50, -50, -50);
verticeNum = x.length;

// Dupliquation des pseudo-sphères en Point1,Point2...
for (c = 0; c < verticeNum; c++) {
   duplicateMovieClip ("Point", "Point" + c, c);
}
// Nous masquon s le point d'héritage
Point._visible = 0;

// Nous définissons les angles selon chaque axe
function setAngle () {
```



```
    Xangle = Xdegrees * (Math.PI / 180);
    Yangle = Ydegrees * (Math.PI / 180);
    Zangle = Zdegrees * (Math.PI / 180);
    //l'angle sera déterminé par la position de la souris
    Xdegrees = this._ymouse;
    Ydegrees = this._xmouse;
    Zdegrees = sqrt(this._xmouse^2+this._ymouse);
}

// Nous calculons les points de chaque sphère
function drawPoints () {
    for (c = 0; c < verticeNum; c++) {
        // On tourne les pseudo-sphères autour de l'axe X en utilisant Xangle
        // et la matrice de rotation
        Ypos_Temp = y[c] * Math.cos (Xangle) + z[c] * Math.sin (Xangle);
        Zpos_Temp = - y[c] * Math.sin (Xangle) + z[c] * Math.cos (Xangle);

        // On tourne les pseudo-sphères autour de l'axe Y en utilisant Yangle
        // et la matrice de rotation
        Xpos_Temp = x[c] * Math.cos (Yangle) - Zpos_Temp * Math.sin (Yangle);
        Zpos = x[c]* Math.sin (Yangle) + Zpos_Temp * Math.cos (Yangle);

        // On tourne les pseudo-sphères autour de l'axe Z en utilisant Xangle
        // et la matrice de rotation
        Xpos = Xpos_Temp * Math.cos (Zangle) + YPos_Temp * Math.sin (Zangle);
        Ypos = - Xpos_Temp * Math.sin (Zangle) + Ypos_Temp * Math.cos (Zangle);

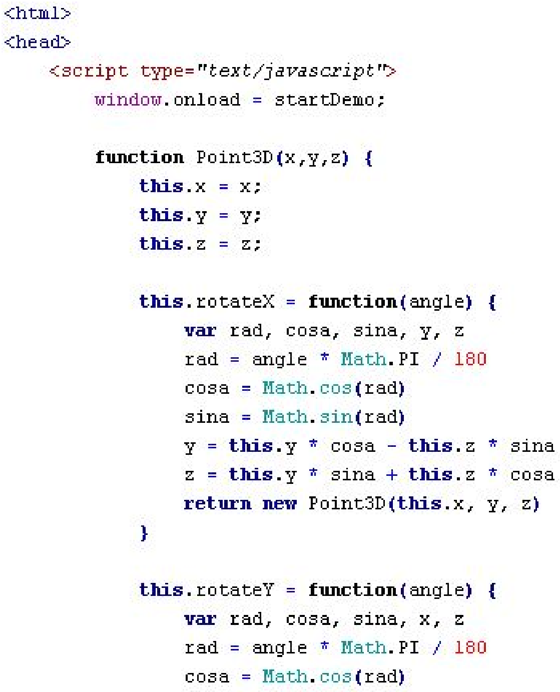
        // Perspective (j'ai rajouté le Zcenter pour être plus exact!
        P = f/ (f + Zpos + Zcenter);

        // On dessine
        this["Point" + c]._x = Xpos * P + Xcenter;
        this["Point" + c]._y = Ypos * P + Ycenter;
        this["Point" + c]._xscale = this["Point" + c]._yscale = P * 100;

        // Z-Sorting
        this["Point" + c].swapDepths(P * 500);
    }
}
```

and here is the final result (the animation below will run for people having a PDF reader with Adobe Flash player installed and activated otherwise see here: `https://vimeo.com/578785768`):

Since the Adobe Flash technology is virtually dead since the time I wrote the code above... an anonymous reader rewrote the above code again into WebGL and here is the corresponding code (if you want to give the same example in other languages don't hesitate):

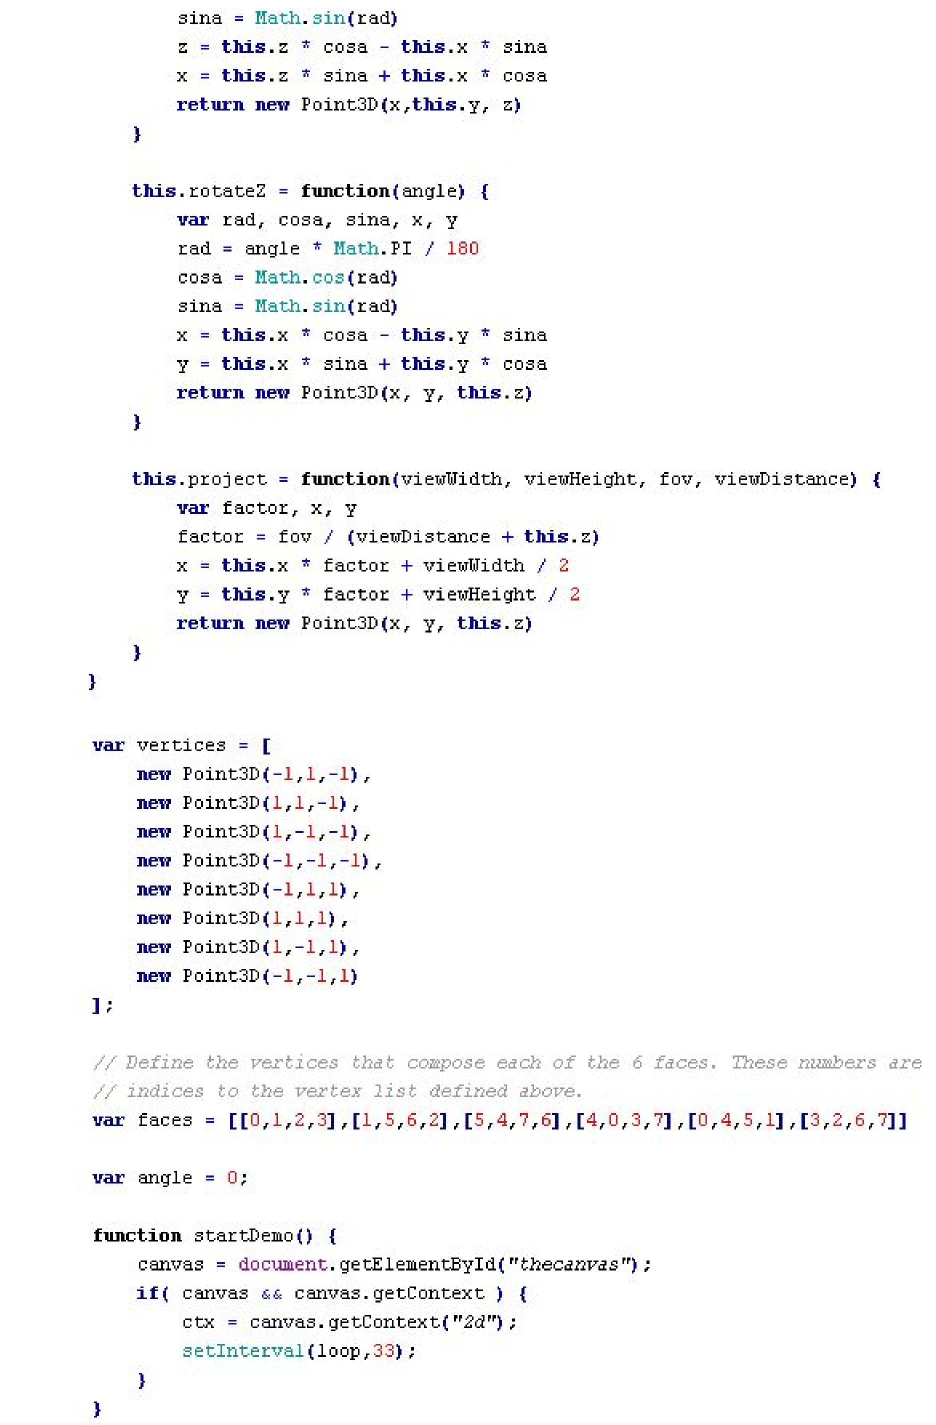


```
<html>
<head>
    <script type="text/javascript">
        window.onload = startDemo;

        function Point3D(x,y,z) {
            this.x = x;
            this.y = y;
            this.z = z;

            this.rotateX = function(angle) {
                var rad, cosa, sina, y, z
                rad = angle * Math.PI / 180
                cosa = Math.cos(rad)
                sina = Math.sin(rad)
                y = this.y * cosa - this.z * sina
                z = this.y * sina + this.z * cosa
                return new Point3D(this.x, y, z)
            }

            this.rotateY = function(angle) {
                var rad, cosa, sina, x, z
                rad = angle * Math.PI / 180
                cosa = Math.cos(rad)
```



```
        sina = Math.sin(rad)
        z = this.z * cosa - this.x * sina
        x = this.z * sina + this.x * cosa
        return new Point3D(x,this.y, z)
    }

    this.rotateZ = function(angle) {
        var rad, cosa, sina, x, y
        rad = angle * Math.PI / 180
        cosa = Math.cos(rad)
        sina = Math.sin(rad)
        x = this.x * cosa - this.y * sina
        y = this.x * sina + this.y * cosa
        return new Point3D(x, y, this.z)
    }

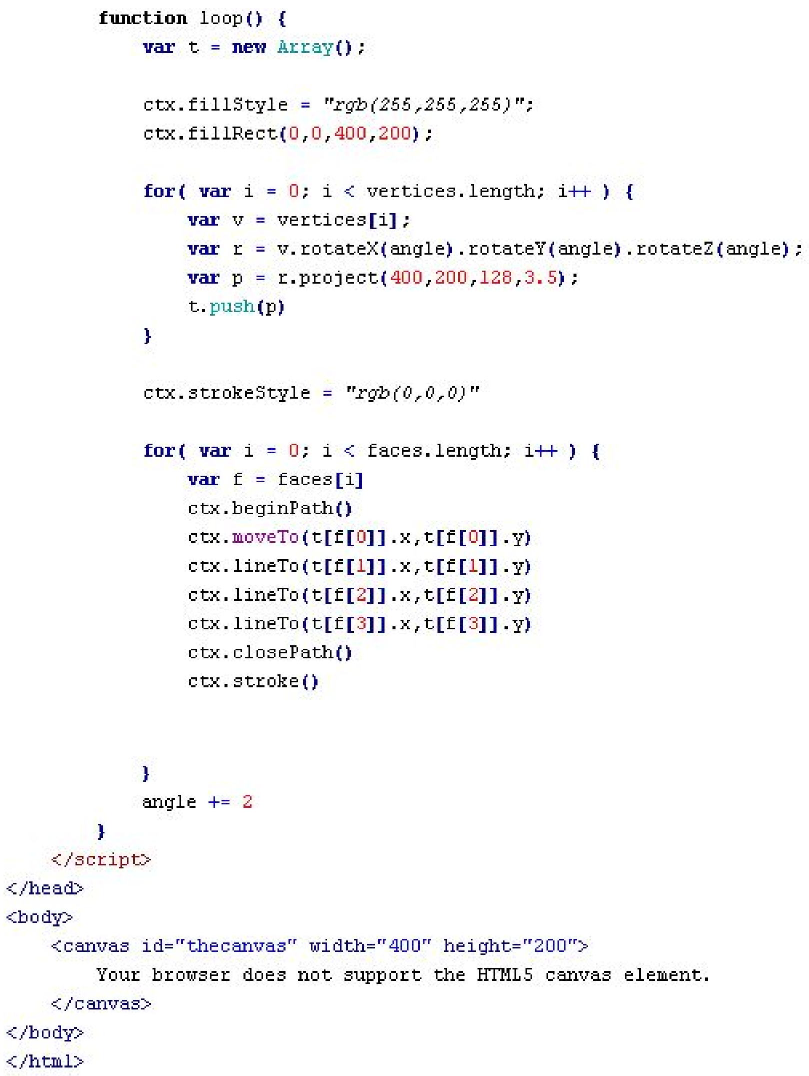
    this.project = function(viewWidth, viewHeight, fov, viewDistance) {
        var factor, x, y
        factor = fov / (viewDistance + this.z)
        x = this.x * factor + viewWidth / 2
        y = this.y * factor + viewHeight / 2
        return new Point3D(x, y, this.z)
    }
}

var vertices = [
    new Point3D(-1,1,-1),
    new Point3D(1,1,-1),
    new Point3D(1,-1,-1),
    new Point3D(-1,-1,-1),
    new Point3D(-1,1,1),
    new Point3D(1,1,1),
    new Point3D(1,-1,1),
    new Point3D(-1,-1,1)
];

// Define the vertices that compose each of the 6 faces. These numbers are
// indices to the vertex list defined above.
var faces = [[0,1,2,3],[1,5,6,2],[5,4,7,6],[4,0,3,7],[0,4,5,1],[3,2,6,7]]

var angle = 0;

function startDemo() {
    canvas = document.getElementById("thecanvas");
    if( canvas && canvas.getContext ) {
        ctx = canvas.getContext("2d");
        setInterval(loop,33);
    }
}
```



```
        function loop() {
            var t = new Array();

            ctx.fillStyle = "rgb(255,255,255)";
            ctx.fillRect(0,0,400,200);

            for( var i = 0; i < vertices.length; i++ ) {
                var v = vertices[i];
                var r = v.rotateX(angle).rotateY(angle).rotateZ(angle);
                var p = r.project(400,200,128,3.5);
                t.push(p)
            }

            ctx.strokeStyle = "rgb(0,0,0)"

            for( var i = 0; i < faces.length; i++ ) {
                var f = faces[i]
                ctx.beginPath()
                ctx.moveTo(t[f[0]].x,t[f[0]].y)
                ctx.lineTo(t[f[1]].x,t[f[1]].y)
                ctx.lineTo(t[f[2]].x,t[f[2]].y)
                ctx.lineTo(t[f[3]].x,t[f[3]].y)
                ctx.closePath()
                ctx.stroke()

            }
            angle += 2
        }
    </script>
</head>
<body>

```

8.4.1.2 Images of Straight Lines

Let us determine from the previous results, the image of a straight line parallel to the ground line (hence the x-axis) of the table XY. In this case, we have:

$$z=a \qquad y=b \tag{8.4.17}$$

where a and b are constants, and for any value of h. This gives us from the relations obtained previously:

$$\begin{aligned} x' &= \frac{\Delta}{\Delta+a}x \\ y' &= h+(b-h)\frac{\Delta}{\Delta+a}=\frac{ha+\Delta b}{\Delta a}=c^{te} \end{aligned} \tag{8.4.18}$$

So as we could expect it, a straight line parallel to the ground line becomes in perspective still a straight line but at a height y' in the XY plane parallel to our screen (it was quite intuitive to guess...).

For any line parallel to the z-axis of the screen (and therefore in its "depth"), we have:

$$x = a \qquad y = b \tag{8.4.19}$$

where a and b are constants for any value of h. Which gives us:

$$\left.\begin{aligned} x' &= \frac{\Delta}{\Delta+z}a \\ y' &= h+(b-h)\frac{\Delta}{\Delta+z} \end{aligned}\right\} : \frac{\Delta}{\Delta+z}=\frac{x'}{a} \Rightarrow y' = h+(b-h)\frac{x'}{a} \tag{8.4.20}$$

The straight lines of equation:

$$y' = h+(b-h)\frac{x'}{a} \tag{8.4.21}$$

all pass through the point $P(x'=0, y'=h)$ when $z \to +\infty$ which is the "main vanishing point" and through the point $P(x'=a, y'=b)$ when $z \to 0$ as shown below in the projection made in Adobe Photoshop (the horizontal lines corresponding to the ground live have been added to give the effect of perspective):

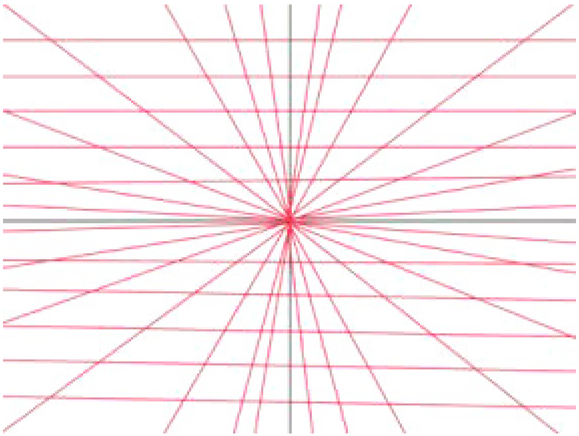

Figure 8.110: **Example of a single vanishing point**

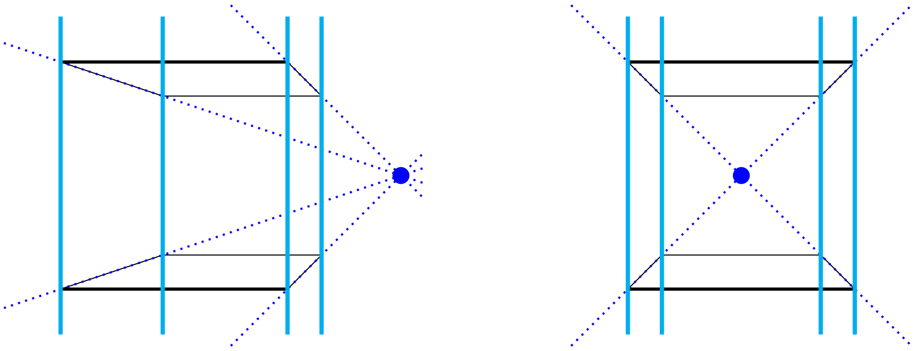
Or in a more academic way:



This is why the shadows from objects seen from the ground seem to diverge (and hence some scientifically illiterate people will claim that therefore the Sun is local...), when in reality seen from the top (in the photo below thanks to a drone) they are indeed parallel because the Sun is quite far (approximately 150 millions kilometres):

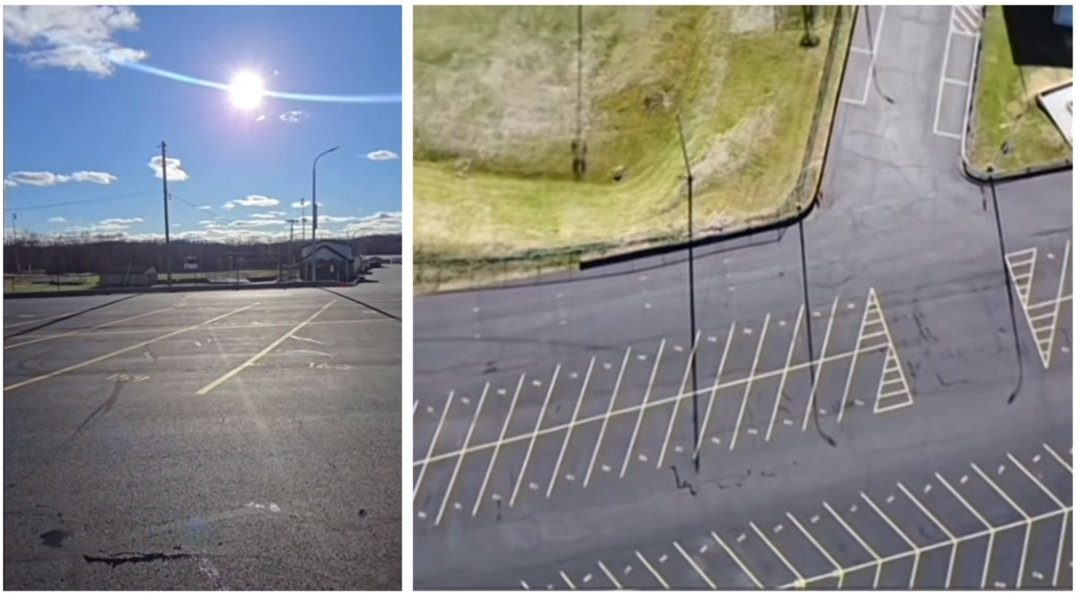


Figure 8.111: **Divergent shadows due to perspective**

From the figure above, we can define the concept of "departure angle" given by the figure below:

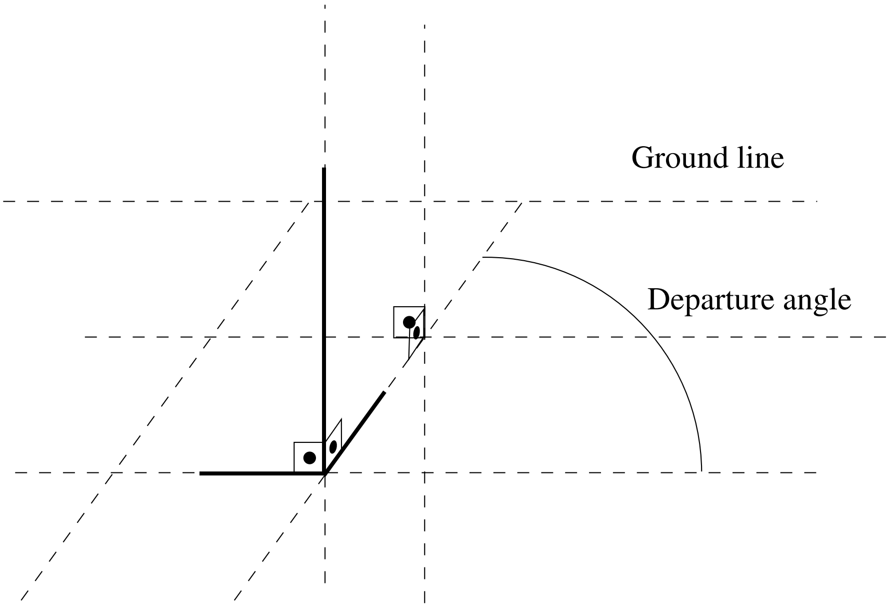

Figure 8.112: **Departure angle**

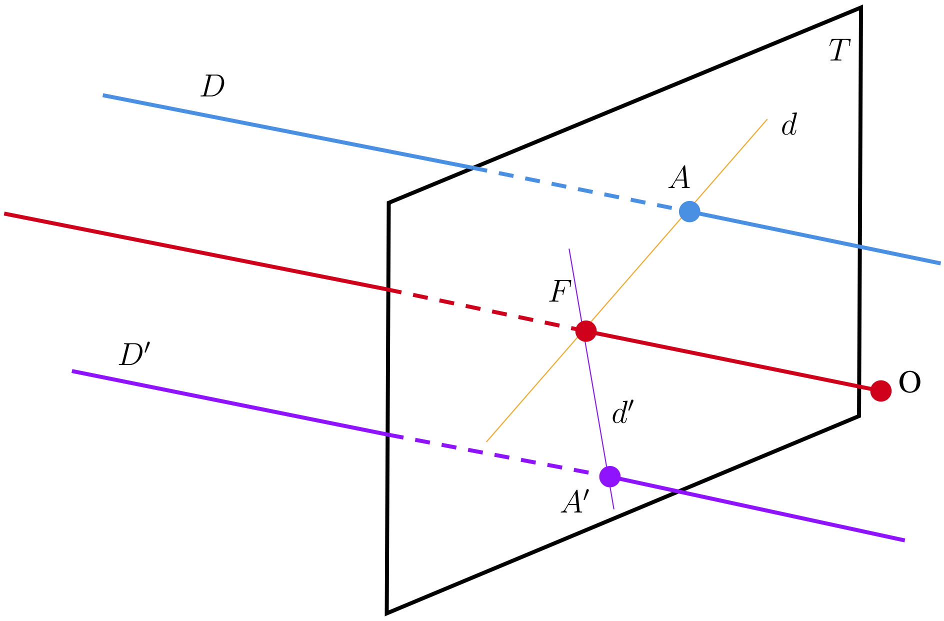
Another geometric representation can perhaps help to better understand the result. Let us recall that the vanishing point of a line (D) is the intersection point F of the table plane T with the line parallel to D passing through O. Two parallel lines (D) and (D') therefore have the same vanishing point (in the perspective point of view obviously!). As shown below:



If we denote by A the intersection point of (D) with T, the perspective drawing of D is the straight line $\overline{AF}$, intersection of T with the plane containing O and D. Since two parallel lines in a conical perspective point of view have the same vanishing point F, they are therefore represented by two intersecting straight lines on F.

For any straight line being in the XZ plane of the screen (i.e. in its "depth"), we have:

$$z=mx+p \tag{8.4.22}$$

and for $y=0$. Which gives us:

$$\begin{gathered}x'=\frac{\Delta}{\Delta+z}x\Rightarrow x=\frac{\Delta+z}{\Delta}x'\\ y'=h+(y-h)\frac{\Delta}{\Delta+z}=h-h\frac{\Delta}{\Delta+z}=\frac{hz}{\Delta+z}\end{gathered} \tag{8.4.23}$$

From the latter equation we deduce:

$$z=-\frac{\Delta}{y'-h}y' \tag{8.4.24}$$

by putting z in the expression of x:

$$x=\left(1+\frac{z}{\Delta}\right)x'=\left(1-\frac{y'}{y'-h}\right)x'=-\frac{hx'}{y'-h} \tag{8.4.25}$$

we replace x and y in the equation of the straight line $z=mx+p$, and once calculations and simplifications made, we find:

$$y'=\frac{mh}{\Delta+p}x'+\frac{ph}{\Delta+p} \tag{8.4.26}$$

Let us consider the particular case of straight lines passing through the opposite vertices of a tile, that is to say inclined at $\pm\pi/4$ therefore with a director coefficient (slope) of ± 1.

The image of these straight lines are then given by:

$$y'=\pm\frac{h}{\Delta+p}x'+\frac{ph}{\Delta+p} \tag{8.4.27}$$

If $y'=h$, then we have following the previous relation:

$$x'=\pm\Delta \tag{8.4.28}$$

this means that any projection of lines of director coefficient ±1 lying in the xy-plane for all x' constitutes secondary vanishing points situated on the same remote horizon line at an equal distance of the main vanishing point as shown below (in the context of a on Adobe Photoshop training, we added a cube is in this perspective):

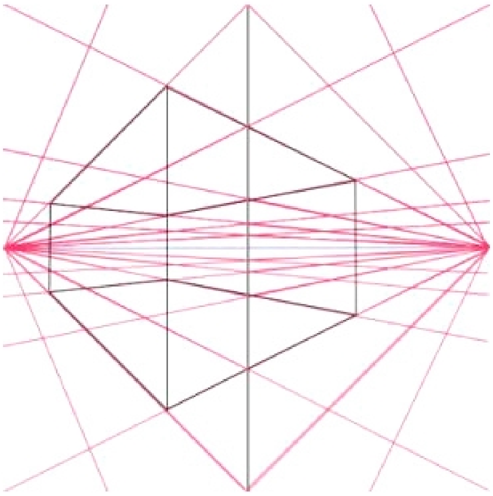


Figure 8.113: **Example of secondary vanishing point**

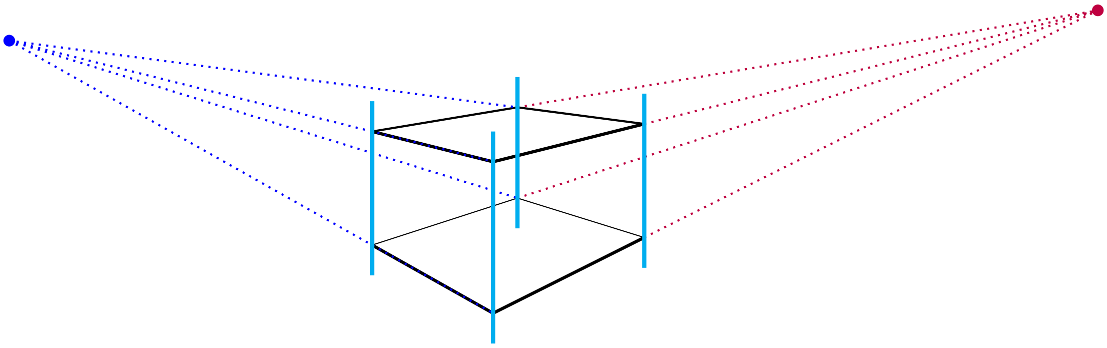
Or in a more academic way:



We see well in the figure above the symmetry about the vertical axis and the two vanishing point that are causing the tiles.

Now let us consider the straight lines parallel to the y-axis of the table (display) and their projection equation if $x=a$ and $z=b$:

$$\begin{aligned}x'&=\frac{\Delta}{\Delta+b}a=c^{te}\\ y'&=h+(y-h)\frac{\Delta}{\Delta+b}\end{aligned} \tag{8.4.29}$$

These right images thus remain straight lines parallel to the y axis. In other words, the right images remain parallel to straight "object" as shown below (for different positions of the observation point):

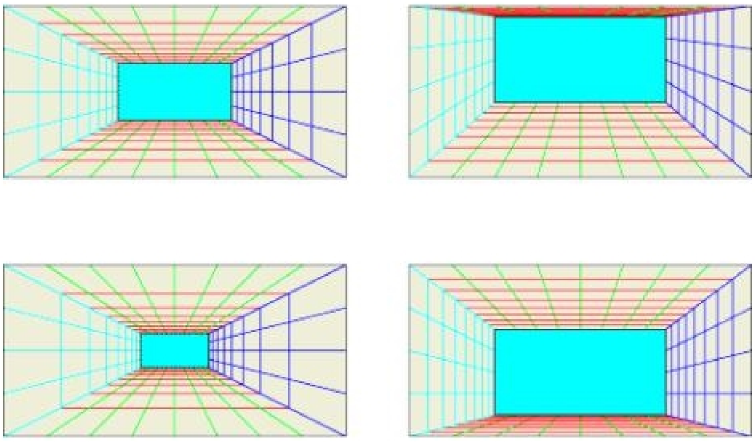


Figure 8.114: Different perspective based on the values of the constants

Let us take for example of this last result, segment of height H whose footer is on the horizontal plane (ground):

$$y = H \qquad x = a \tag{8.4.30}$$

The height of the segment is given by:

$$y' = H' = h + (H - h)\frac{\Delta}{\Delta + b} \tag{8.4.31}$$

Let us consider now $x = a$, that is to say the vertical columns of height H are aligned on the line $x = a$:

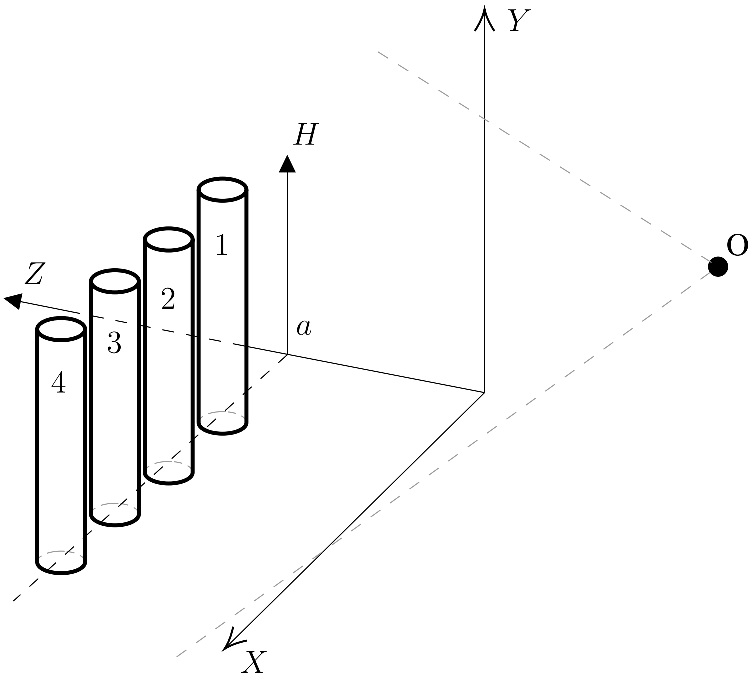

Figure 8.115: Aligned columns perspective problem

Let us calculate the coordinates of the vertices of these images:

$$\begin{aligned} x' &= \frac{\Delta}{\Delta+b}a \Rightarrow \frac{\Delta}{\Delta+b}=\frac{x'}{a} \\ y' &= H' = h+(H-h)\frac{\Delta}{\Delta+b}=h+\frac{H-h}{a}x \end{aligned} \tag{8.4.32}$$

This is obviously still the equation of a straight line and let us notice that all these line pass trough the point of coordinates $(x'=0, y'=h)$ that is just the main vanishing point!

So as we experiment in real life, if we consider the above figure corresponding to the previous developments when $H<h$ the columns seems to have their height that decrease as the are more far from the observer and if $h>H$ the columns height seems to increase.

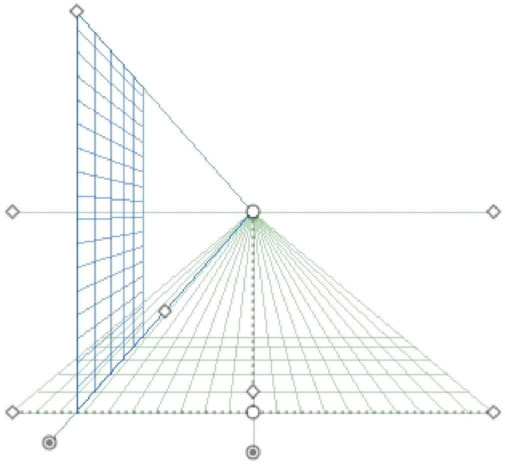
From the previous discussion, we have therefore also obviously a new method for rotating object in three dimensional space. Instead of rotating the object around different axes, we can imagine using the above equations to rotate the viewer around the object (that is a point of view...).

We have considered so far only the projective perspective on a plane. By the way, to work on any projection methods (sphere on a plane, plane on a sphere, sphere on sphere, anything about anything) it is simply enough to extend the analysis that we made above in a coordinate system suitable for the studied system (polar coordinates, cylindrical coordinates, spherical coordinates, ...). This is probably that way that some 3D simulation software use to project an image on a reflective surface such as a semi-transparent undulated glass at the difference that on computer a surface don't have an infinite number of points but a limited number of pixels and therefore the projection need some smoothing trough special interpolation techniques.

Remark

From the results we have obtained above, we can extract an interesting and intuitive conclusion For an observer of a picture or a table seethe image as it was originally, it must be placed at specific coordinates of the table (of the picture or of the table).

Software such as Adobe Illustrator offers since the early 12010s (holocene calendar) a tool to create perspectives for one vanishing point, for two vanishing points and three vanishing points:



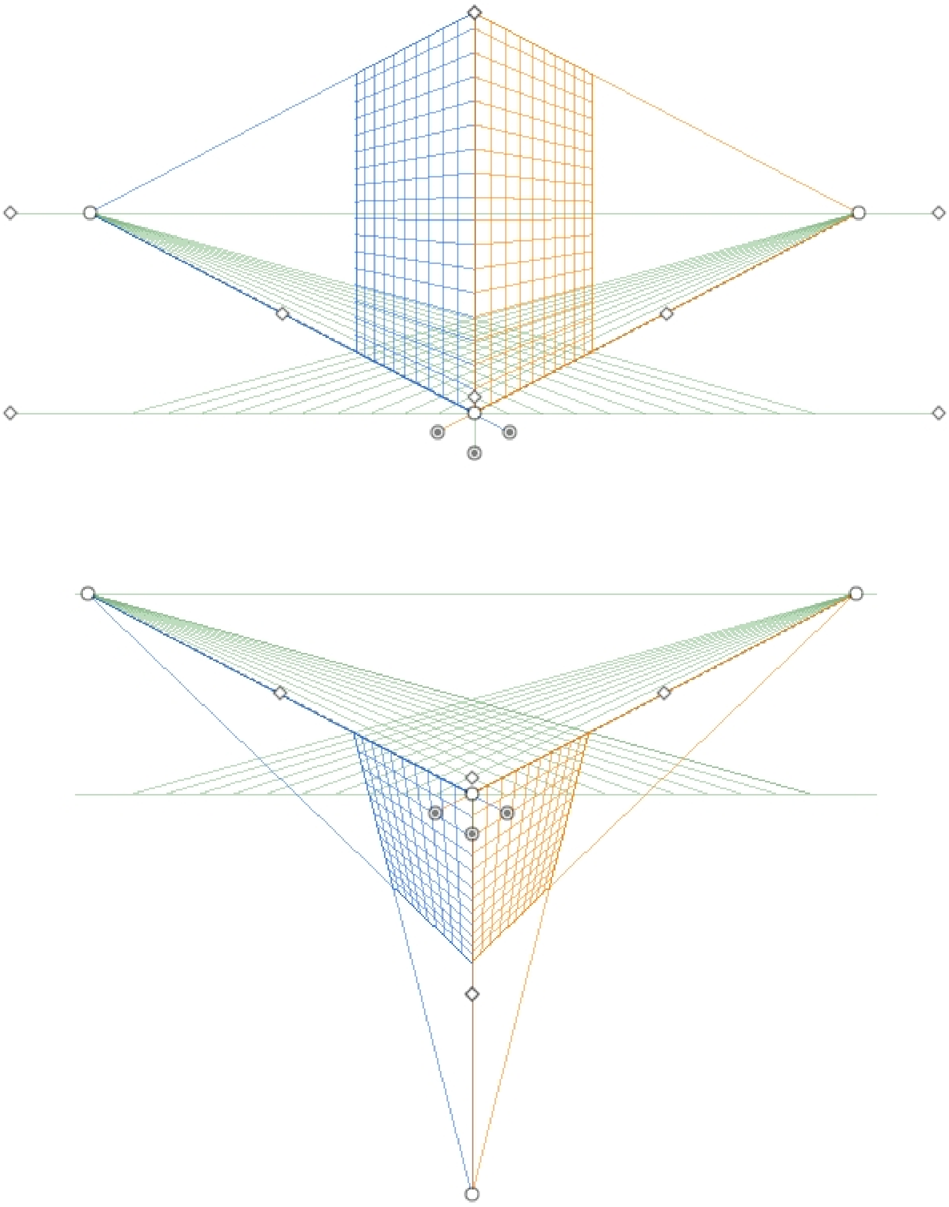


Figure 8.116: **One, two and three vanishing points in Adobe Illustrator**

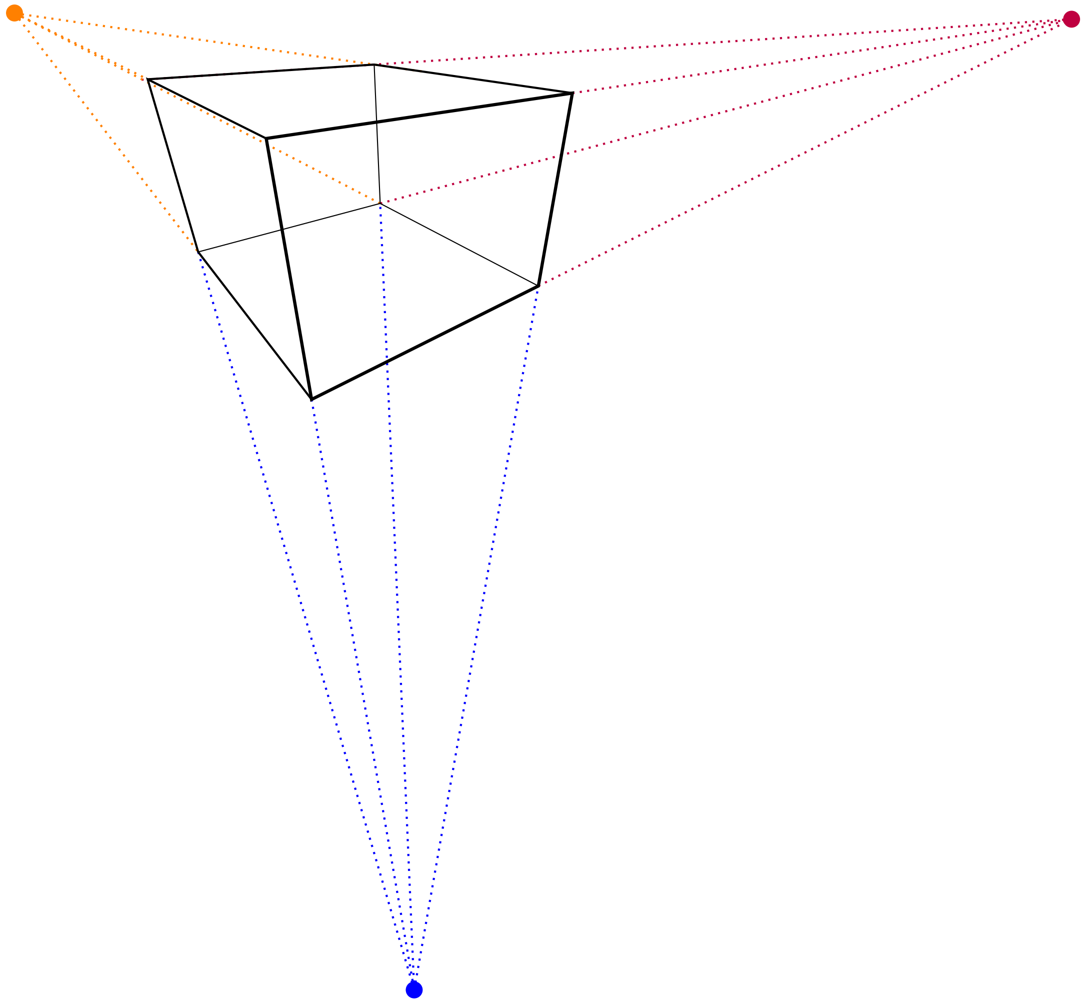
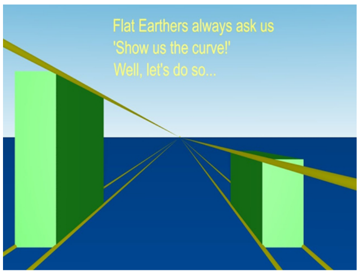
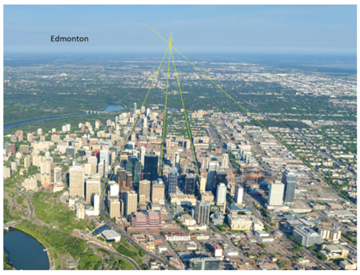
Or in a more academic way:



And to finish a wink for all our favourite flat earthers (...):



Flat Earthers always ask us
'Show us the curve!'
Well, let's do so...



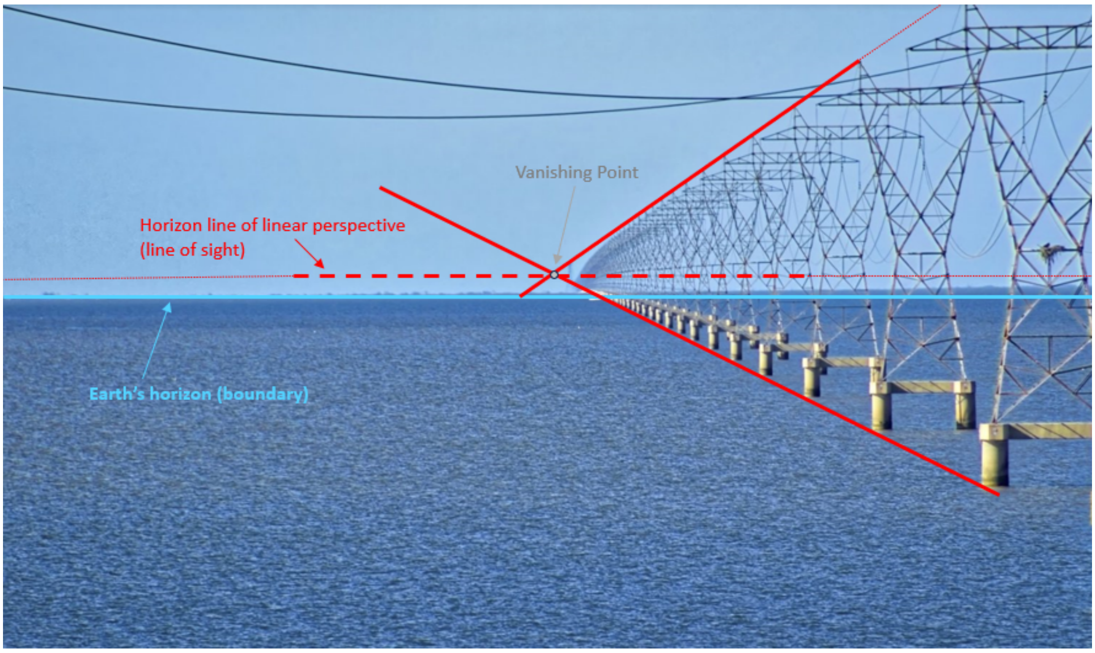
Medicine Head Alberta

Antwerp docks

Antwerp Kieldrecht lock

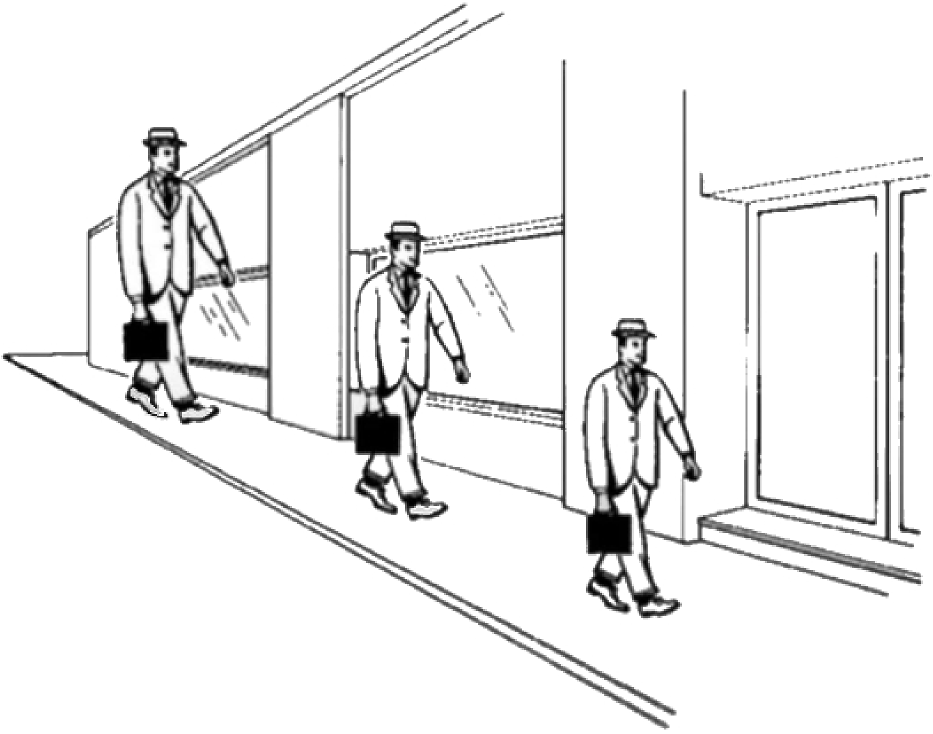
Washington D.C.

And a last good one with a reminder to not confuse the boundary of an object on a projection and the horizon line (line of sight):



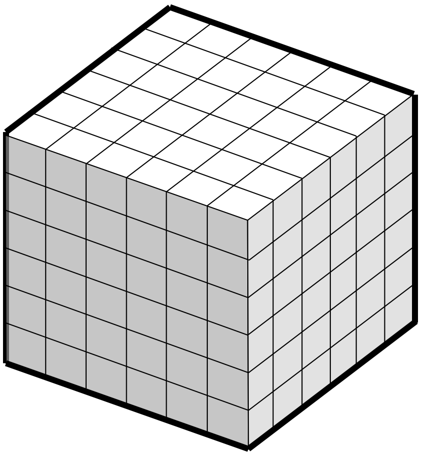
Vanishing Point
Horizon line of linear perspective
(line of sight)
Earth's horizon (boundary)

The reader must keep in mind that the human eye and brain are not very precise nor accurate and unbiased tools ton investigate Nature. A basic well known example is the illustration below involving linear perspective where the individual seems to have different heights when in reality with a ruler we can check that their height is always the same...:

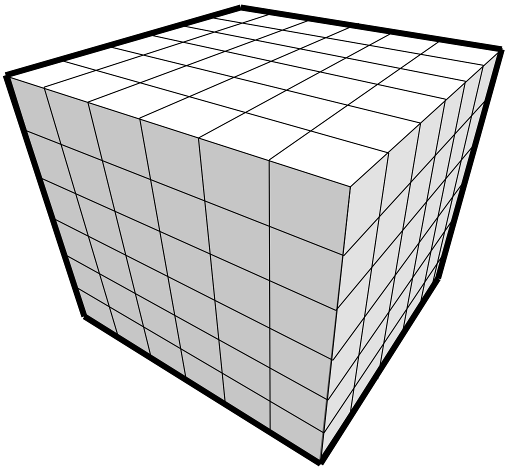


8.4.2 Affine projections

Although the best method of perspective representation is the conical perspective method, we can not always tolerate to do a large quantity of computation to represent a volume. Thus, it is possible to define projection techniques that result from an approximation of the mathematical results obtained previously to get two new techniques (there are more but these two perspectives we will see further below are by far the most used) which we see daily on many technical papers or artistic works. These two techniques are respectively the "isometric projection" and "orthogonal projection" that are part of the family of "affine projections" (in fact the use of the word "projection" must be understood as "projection on the Table of the observer" and therefore it is also a perspective).



isometric projection



perspective projection

An example of projective transformation that is not affine is photography through a Camera:

Definition (#8.4.354): An "affine projection" of the usual 3-dimensional space is an affine transformation that sends all the points of this space on a same plane of this space. If the point $M(x, y, z)$ is not on the projection plane, he and its image $m(x', y', z')$ form a line whose direction is constant: we name it the "projection direction". The corresponding perspective is named "parallel perspective" or "cylindrical perspective".

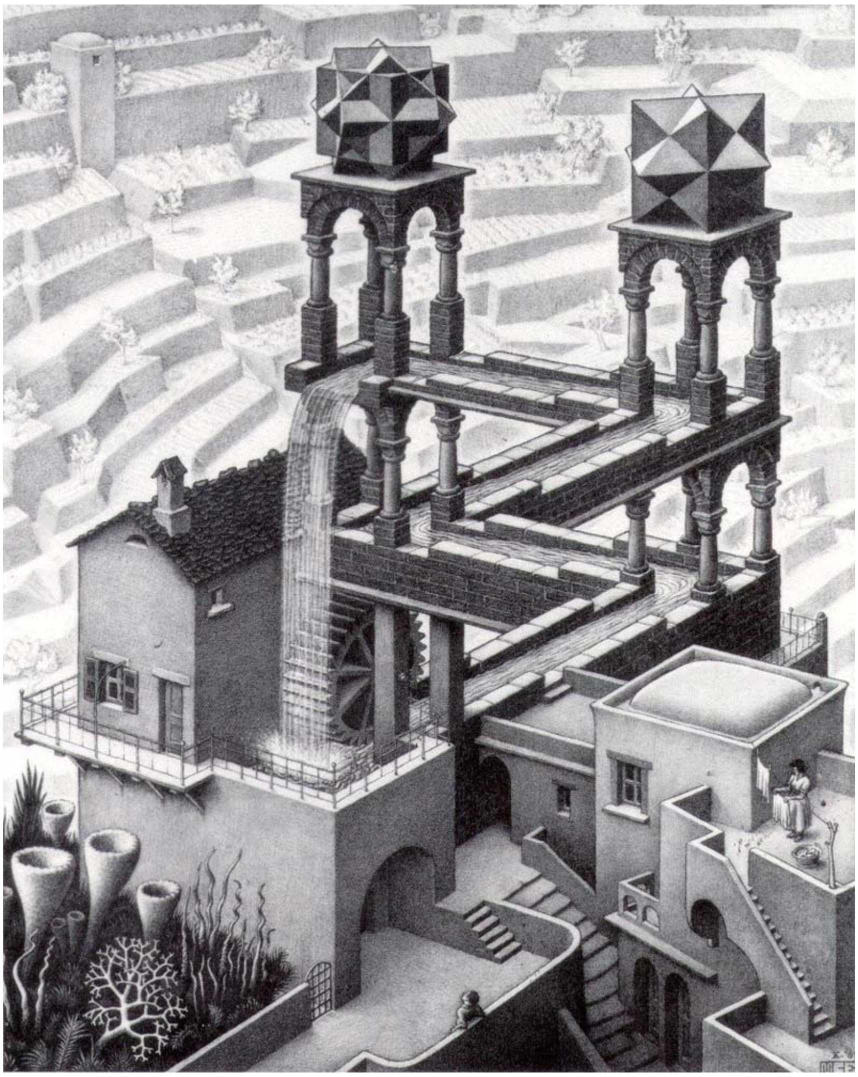
Like all affine transformations of space, an affine projection preserves:

- The parallelism between the lines
- The barycenter, that is all the proportions existing on a given line

Only the lengths and angles within a parallel plane to the projection plane are kept.

Let us present briefly these two techniques because they must be part of the general culture of the engineer.

Like all projections and all perspective, the loss of the third dimension and the non-respect of real mathematical transformation induces possible errors of interpretation. This has been extensively used by the artist M. C. Escher to create impossible situations:



8.4.2.1 Isometric perspective

Isometric projection is a method for visually representing three-dimensional objects in two dimensions in technical and engineering drawings. It is a parallel projection (object is rotated along one or more of its axes relative to the plane of projection) in which the three coordinate axes appear equally foreshortened (hence the "iso") and the angle between any two of them is approximated to 120 degrees ($2\pi/3$ [rad]):

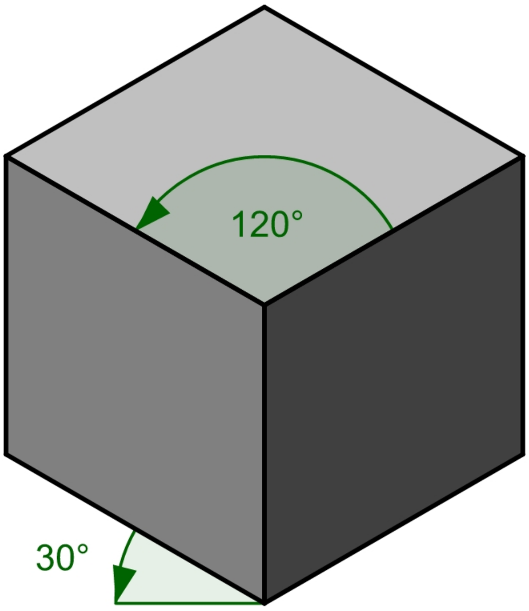


Figure 8.117: **Isometric angles (source: Wikipedia)**

Indeed, as we will see during our study of Analytical Geometry, the angle of 30° above is only an approximation of the angle between the xy-plane and the (isometric) plane vertical to the vector $\vec{n}=(1,1,1)$ passing through the corner of a cube of equal sides of length 1. In fact the choice of the angle is empirical and for example in computer games it varies between 30° and 60° depending on the game editor.

Let us consider some 3D shapes using the isometric drawing method. In the figure below coming from Wikipedia (year 12016 according to holocene calendar) the black dimensions are supposed true lengths as found in an orthographic projection (see further below). The red dimensions are used when drawing with the isometric drawing method. The same 3D shapes drawn in isometric projection would appear smaller; an isometric projection will show the object's sides foreshortened, by approximately 80%.

In fact we will see that the figure below coming from Wikipedia (year 12016 according to holocene calendar) is in fact quite wrong or at least can bring the reader to some misunderstanding!!!!

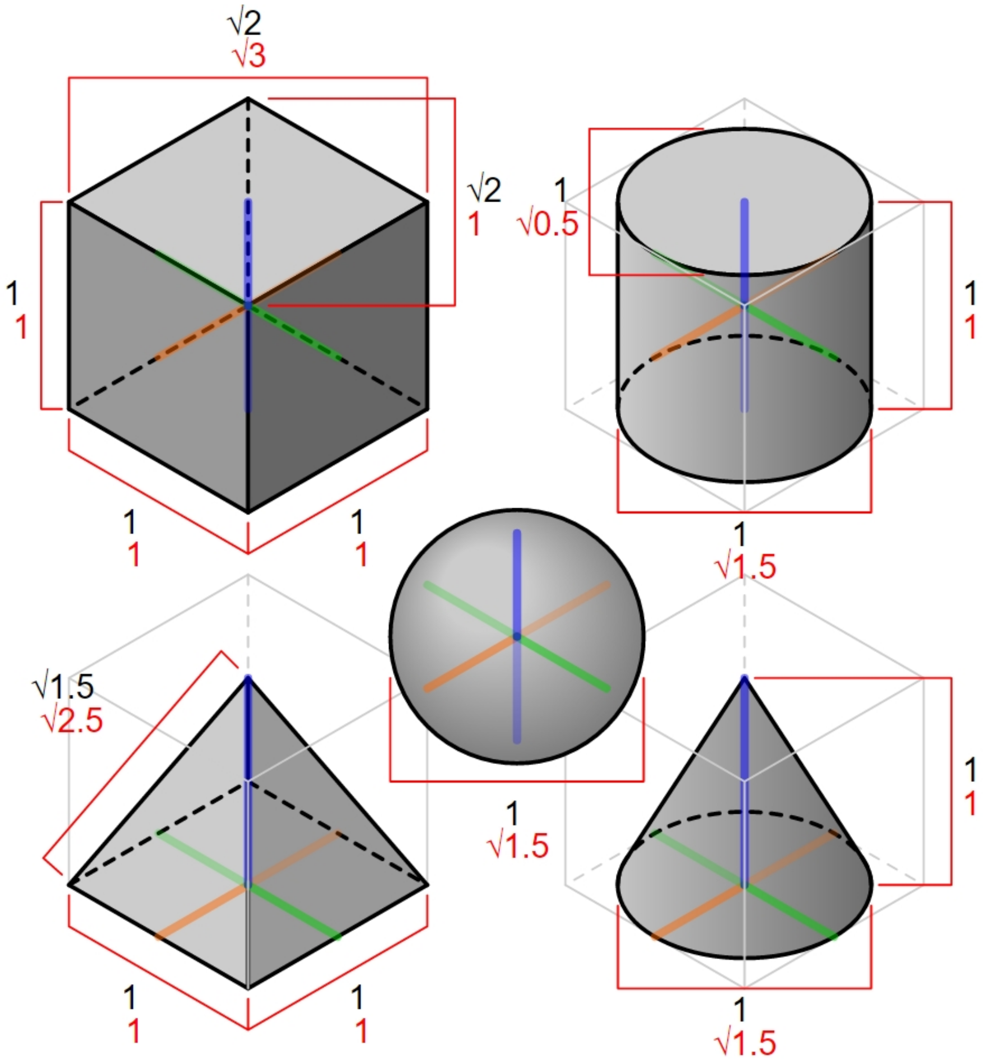

Figure 8.118: **Isometric volumes (source: Wikipedia)**

Ok let us see closer to the figure above. To prove where this values comes from we need to use the change of basis mathematics tools (see section Linear Algebra page 1992). This will be a veeery nice application of Linear Algebra and Vector Calculus!!!

So let us consider the following situation:

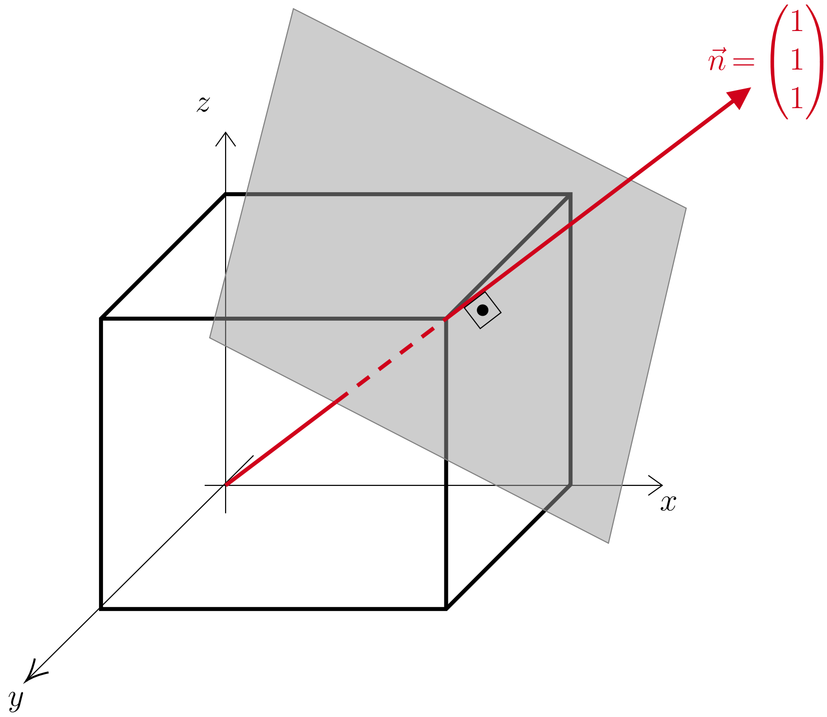

Figure 8.119: **Isometric plane to find the cube dimensions**

To simplify the determination of the new basis in the plane we well make pass our plane trough the origin (isometric affine plane) such that its equation becomes therefore:

$$x+y+z=0 \tag{8.4.33}$$

Obviously as our plane is perpendicular to $\vec{n}=(1,1,1)$ it comes immediately that a first basis vector of our orthonormal 2D basis will be the vector:

$$\vec{u}_1=\begin{pmatrix}-1\\-1\\2\end{pmatrix} \tag{8.4.34}$$

We can easily control that this point belongs well to our isometric affine plane of equation:

$$x+y+z=0 \tag{8.4.35}$$

by just replacing the values and see that the equality holds.

Now we are looking for the second orthonormal vector of our plane basis. So we first simply use the cross product:

$$\vec{u}_2=\vec{n}\times\vec{u}_1=\begin{pmatrix}1\\1\\1\end{pmatrix}\times\begin{pmatrix}-1\\-1\\2\end{pmatrix}=\begin{pmatrix}3\\-3\\0\end{pmatrix} \tag{8.4.36}$$

We can also easily control that this point belongs well to our isometric affine plane.

And we must normalize to the unit so that finally:

$$\vec{u}_1=\frac{1}{\sqrt{6}}\begin{pmatrix}-1\\-1\\2\end{pmatrix} \qquad \vec{u}_2=\frac{1}{\sqrt{18}}\begin{pmatrix}3\\-3\\0\end{pmatrix} \tag{8.4.37}$$

Now we calculate the images of the vectors of the canonical basis $(\vec{e}_1,\vec{e}_2,\vec{e}_3)$ by the orthogonal projection on our isometric affine plane P:

$$\begin{gathered}\text{proj}_P\vec{e}_1=(\vec{e}_1\circ\vec{u}_1)\vec{u}_1+(\vec{e}_1\circ\vec{u}_2)\vec{u}_2=-\frac{1}{6}\begin{pmatrix}-1\\-1\\2\end{pmatrix}+\frac{1}{6}\begin{pmatrix}3\\-3\\0\end{pmatrix}=\frac{1}{3}\begin{pmatrix}2\\-1\\-1\end{pmatrix}\\ \text{proj}_P\vec{e}_2=(\vec{e}_2\circ\vec{u}_1)\vec{u}_1+(\vec{e}_2\circ\vec{u}_2)\vec{u}_2=-\frac{1}{6}\begin{pmatrix}-1\\-1\\2\end{pmatrix}-\frac{1}{6}\begin{pmatrix}3\\-3\\0\end{pmatrix}=\frac{1}{6}\begin{pmatrix}-2\\4\\-2\end{pmatrix}=\frac{1}{3}\begin{pmatrix}-1\\2\\-1\end{pmatrix}\\ \text{proj}_P\vec{e}_3=(\vec{e}_3\circ\vec{u}_1)\vec{u}_1+(\vec{e}_3\circ\vec{u}_2)\vec{u}_2=\frac{4}{6}\begin{pmatrix}-1\\-1\\2\end{pmatrix}-0=\frac{2}{3}\begin{pmatrix}-1\\-1\\2\end{pmatrix}=\frac{1}{3}\begin{pmatrix}-2\\-2\\4\end{pmatrix}\end{gathered} \tag{8.4.38}$$

Finally the projection matrix in the canonical basis is:

$$\boxed{Z=\frac{1}{3}\begin{bmatrix}2&-1&-2\\-1&2&-2\\-1&-1&4\end{bmatrix}} \tag{8.4.39}$$

Ok now let us consider the projection of the origin $(0,0,0)$ we then have obviously:

$$\frac{1}{3}\begin{bmatrix}2&-1&-2\\-1&2&-2\\-1&-1&4\end{bmatrix}\begin{pmatrix}0\\0\\0\end{pmatrix}=\begin{pmatrix}0\\0\\0\end{pmatrix} \tag{8.4.40}$$

and now one of its X or Y unit vector :

$$\frac{1}{3}\begin{bmatrix}2&-1&-2\\-1&2&-2\\-1&-1&4\end{bmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix}=\frac{1}{3}\begin{pmatrix}2\\-1\\-1\end{pmatrix} \tag{8.4.41}$$

So we get for the norm of the distance of a unit vector of the original base of the XY-plane:

$$\sqrt{\frac{2^2}{3^2}+\frac{(-1)^2}{3^2}+\frac{(-1)^2}{3^2}}=\sqrt{\frac{6}{9}}=\sqrt{\frac{2}{3}} \tag{8.4.42}$$

And finally the unit vector along the z-axis:

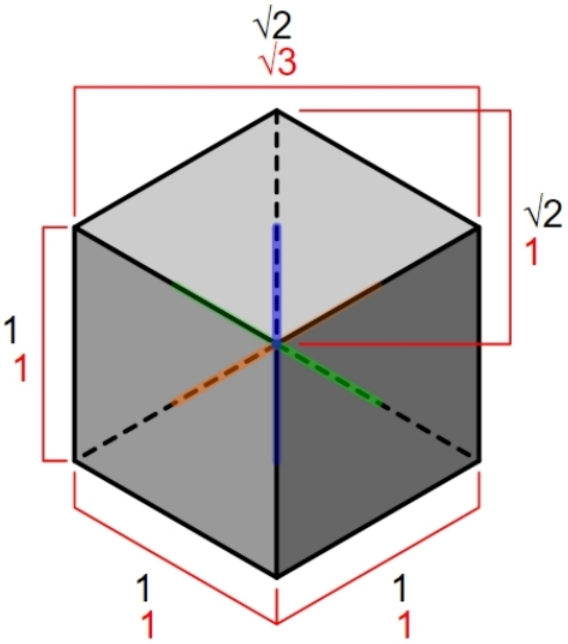
$$\frac{1}{3}\begin{bmatrix}2&-1&-2\\-1&2&-2\\-1&-1&4\end{bmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}=\frac{1}{3}\begin{pmatrix}-2\\-2\\4\end{pmatrix} \tag{8.4.43}$$

So we get for the norm of the distance of a unit vector of the original base along the Z-axis:

$$\sqrt{\frac{2^2}{3^2}+\frac{(-2)^2}{3^2}+\frac{(4)^2}{3^2}}=\sqrt{\frac{24}{9}}=\sqrt{\frac{8}{3}}\cong 2.828 \tag{8.4.44}$$

So now let us come back on Wikipedia's figure:

- First the cube...



So the real sides of a cube of side length equal to 1 transform same as the basis vector as seen just before. That is to say an isometric transformation through Z gives for the sides in or parallel to the XY plane:

$$Z:1\rightarrow\sqrt{\frac{2}{3}} \tag{8.4.45}$$

and along the Z-axis:

$$Z:1\rightarrow\sqrt{\frac{8}{3}} \tag{8.4.46}$$

So when Wikipedia says that the distances are shortened this is true... but they omit to say that this is only in two space directions. Also when on the figure they show that 1 in real dimensions is equal to 1 for the sides in isometric perspective is completely false.

The distance between the two horizontal top vertices is given by the calculation of the norm of the projection:

$$\begin{pmatrix}1\\0\\1\end{pmatrix}-\begin{pmatrix}0\\1\\1\end{pmatrix}=\begin{pmatrix}1\\-1\\0\end{pmatrix} \tag{8.4.47}$$

So:

$$\frac{1}{3}\begin{bmatrix}2&-1&-2\\-1&2&-2\\-1&-1&4\end{bmatrix}\begin{pmatrix}1\\-1\\0\end{pmatrix}=\frac{1}{3}\begin{pmatrix}3\\-3\\0\end{pmatrix} \tag{8.4.48}$$

So the norm is:

$$\sqrt{\frac{3^2}{3^2}+\frac{(-3)^2}{3^2}+\frac{0^2}{3^2}}=\sqrt{2} \tag{8.4.49}$$

And therefore the original diagonal transforms to:

$$Z:\sqrt{2}\rightarrow\sqrt{2} \tag{8.4.50}$$

So once again Wikipedia is wrong. In fact on Wikipedia they take for original sides size the inverse of $\sqrt{2/3}$, that is to say $\sqrt{3/2}$. Indeed we have in this case:

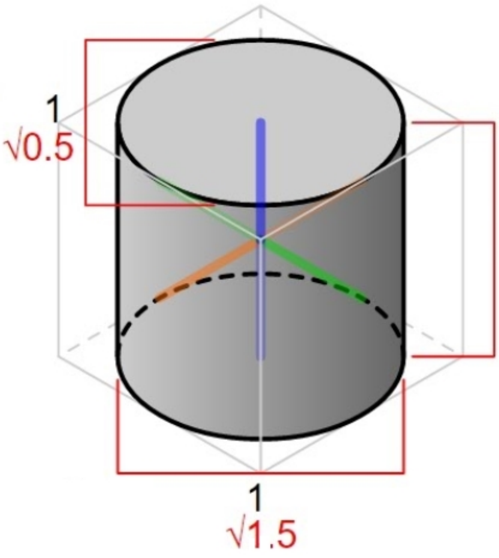
$$\frac{1}{3}\begin{bmatrix}2 & -1 & -2\\ -1 & 2 & -2\\ -1 & -1 & 4\end{bmatrix}\sqrt{\frac{3}{2}}\begin{pmatrix}1\\ -1\\ 0\end{pmatrix}=\frac{1}{\sqrt{3}\sqrt{2}}\begin{pmatrix}1\\ -5\\ 4\end{pmatrix} \tag{8.4.51}$$

So the norm is:

$$\sqrt{\frac{3^2}{(\sqrt{3}\sqrt{2})^2}+\frac{(-3)^2}{(\sqrt{3}\sqrt{2})^2}+\frac{0^2}{(\sqrt{3}\sqrt{2})^2}}=\frac{1}{\sqrt{3}\sqrt{2}}\sqrt{2\cdot 3^2}=\frac{3}{\sqrt{3}}=\sqrt{3} \tag{8.4.52}$$

So we fall back on the value given by Wikipedia...

- Second the cylinder...



The height of the cylinder follows exactly the same procedure as for the cube and the remark relatively to Wikipedia's figure remains the same!

So what will interest us here is especially the "isometric ellipse" (also named "isocircle") visible in the figure above and we will focus on the minor and major axes of that latter.

First, to find these values we need to project the circle on the isometric plane. The figure (where we added a circle on the cube) is given now by:

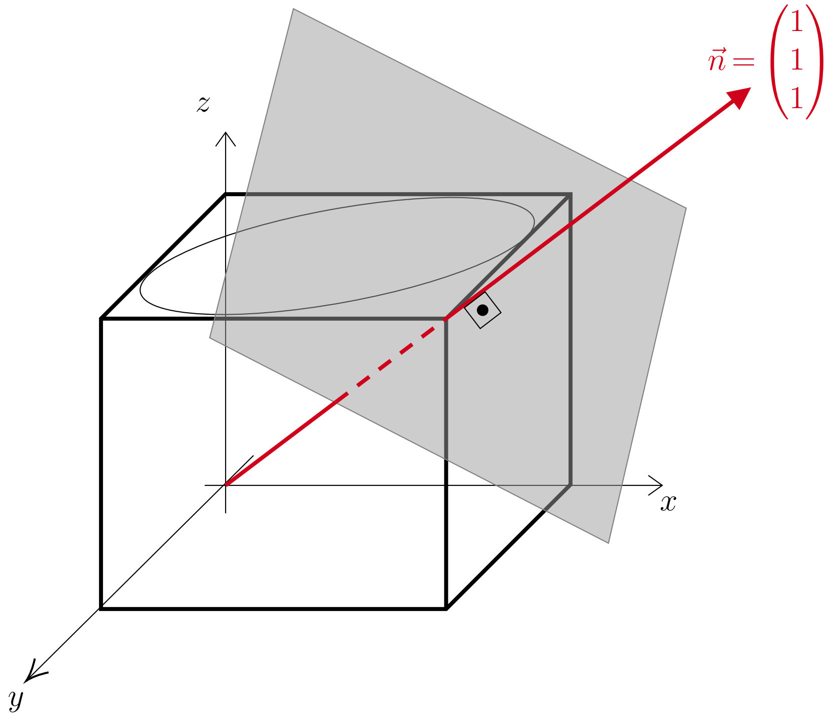


Figure 8.120: Isometric plane to find the isocircle dimensions

To finish depending on donations

8.4.2.2 Oblique perspective

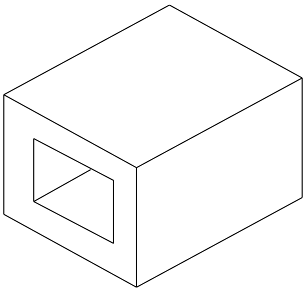
Let us take a view (eg the front view), and let us name the axes "x" (horizontal) and y (vertical) as usual. The z-axis being the axis perpendicular to the view (also as usual).

In isometric projection, we plot the z-axis with an angle relative to the x axis (for example $\pi/6$ ($30°$) or sometimes $\pi/4$ ($45°$)), and we report then the distances by multiplying by a coefficient less than 1 that is empirical on by using trigonometric basic rules.

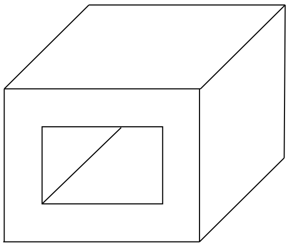
Remark

The oblique projections for all angles other than $\pi/4$ are named "Cavalier projection". When the angle is equal to $\pi/4$ we then speak of "Cabinet projection".

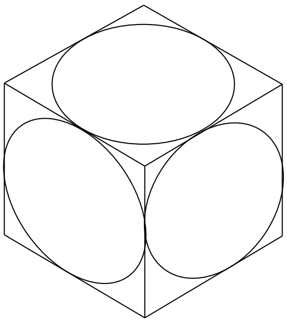
Oblique projection is a simple type of technical drawing of graphical projection used for producing two-dimensional images of three-dimensional objects. The objects are not in perspective, so they do not correspond to any view of an object that can be obtained in practice, but the technique does yield somewhat convincing and useful images:



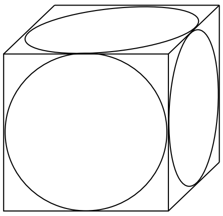
Isometric Pictorial



Oblique Pictorial



Isometric Pictorial



Oblique Pictorial

In the oblique pictorials coordinate system only one axes is at an angle. The angle may range between 0 and 90 degrees ($\pi/2$ [rad]); however, the most commonly used angle is 45 degrees.

It is thus often used when a figure must be drawn by hand, e.g. on a black board (lesson, oral examination).

8.4.2.3 Orthogonal projection

If the projection direction is orthogonal to the plane of projection, then the perspective becomes transforms a sphere into a simple circle. This is a type of perspective drawing used as an alternative to the conical perspective (with which it will also coincide when the eye of the observer is placed infinitely far away from the "table").

The simplest orthogonal projection to express is obviously the one that sends space on a plane parallel to the table, this is the "parallel orthogonal projection" or "orthographic projection", of distance d. In other words, such that for example for the "above view" we have for any point of the volume:

$$M(x,y,z)\rightarrow m(x,y,d) \tag{8.4.53}$$

So we trivially obtain all the coordinates in an orthonormal 2D frame proper to this plane itself where $x=x'$ and $y=y'$:

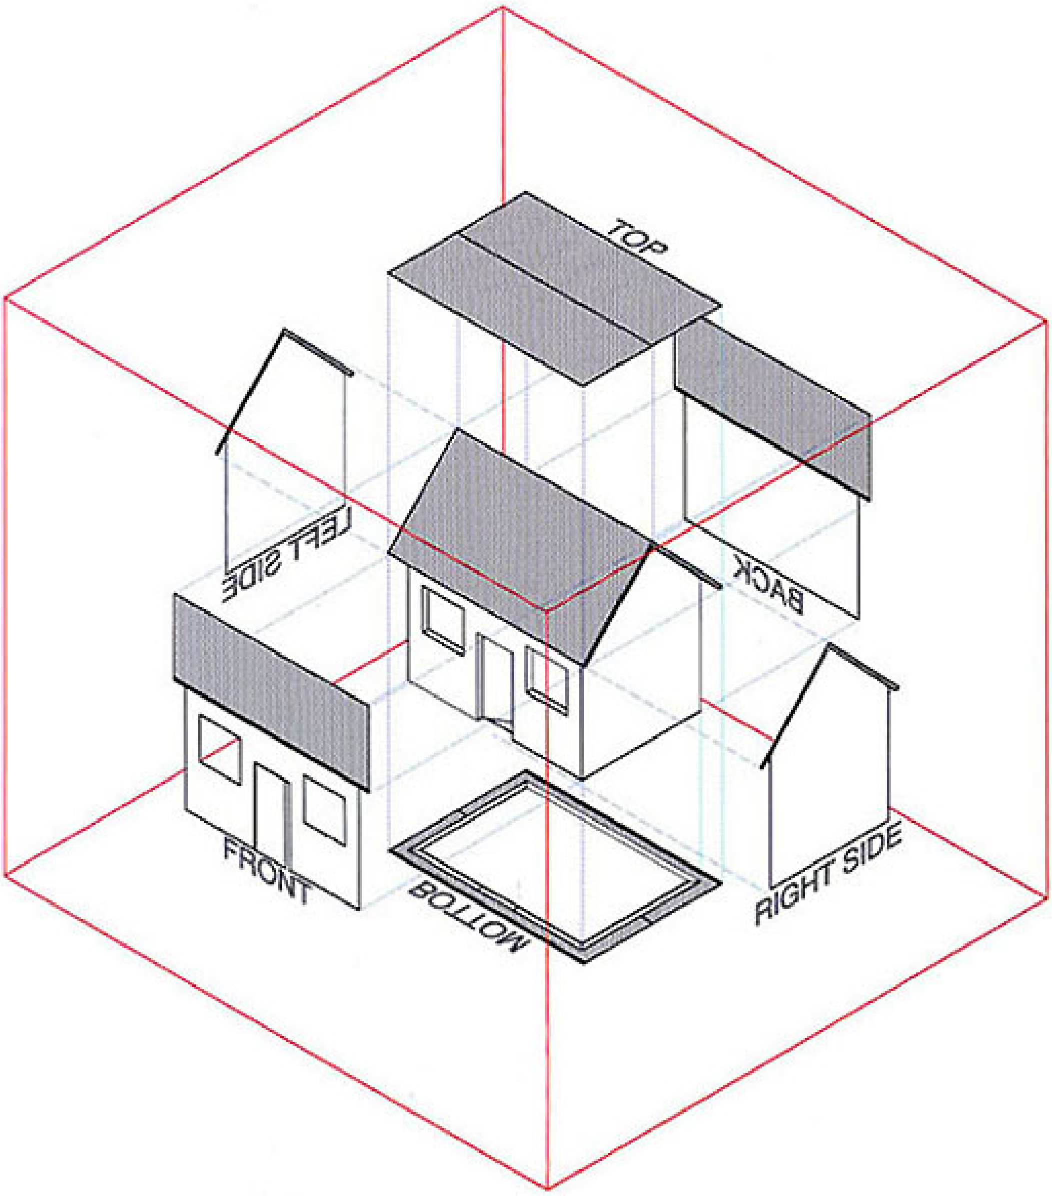


Figure 8.121: **Orthogonal projection in real life...**

Nowadays, softwares like AutoCAD, Inventor, Cathia and so on... generate automatically orthogonal projections from an isometric view of a drawing.

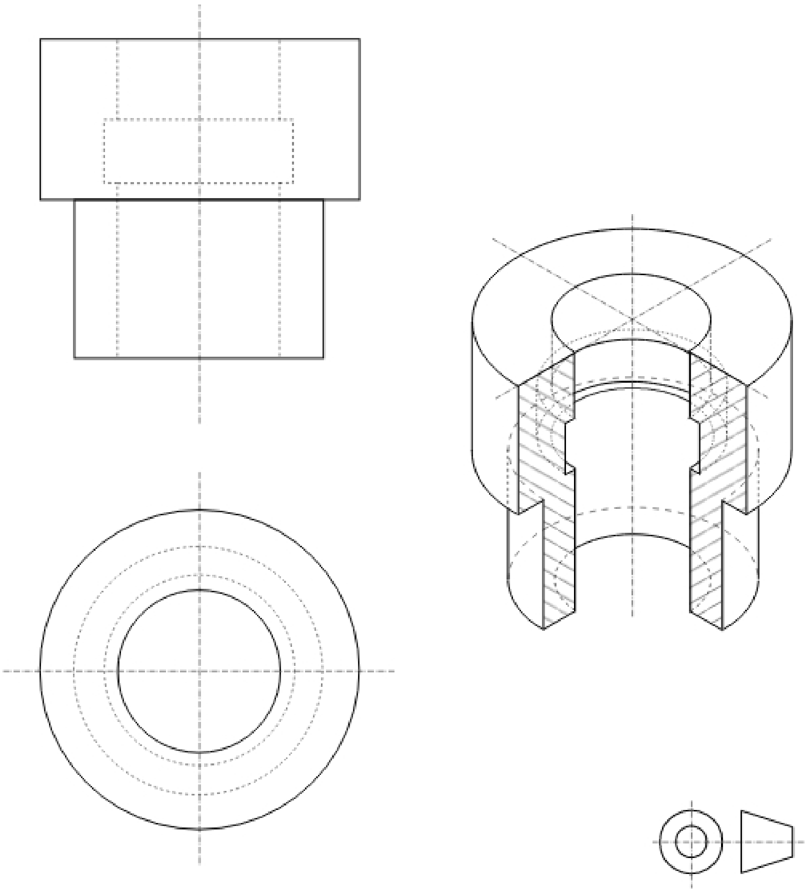

Figure 8.122: **Orthogonal Projection with a software**

In computer graphics, one of the most common matrices used for orthographic projection can be defined by a 6-tuple, (left, right, bottom, top, near, far), which defines the clipping planes (that is, the region of eye space that contains all the geometry you want to display). These planes form a box with the minimum corner at (left, bottom, -near) and the maximum corner at (right, top, -far). The box is then translated so that its center is at the origin, then it is scaled to the unit cube which is defined by having a minimum corner at $(-1,-1,-1)$ and a maximum corner at $(1,1,1)$.

The orthographic transform to get the canonical can be given by the following matrix:

$$\boxed{C_V=\begin{bmatrix}\frac{2}{\text{right}-\text{left}} & 0 & 0 & -\frac{\text{right}+\text{left}}{\text{right}-\text{left}}\\ 0 & \frac{2}{\text{top}-\text{bottom}} & 0 & -\frac{\text{top}+\text{bottom}}{\text{top}-\text{bottom}}\\ 0 & 0 & \frac{-2}{\text{far}-\text{near}} & -\frac{\text{far}+\text{near}}{\text{far}-\text{near}}\\ 0 & 0 & 0 & 1\end{bmatrix}} \tag{8.4.54}$$

which is in fact obviously a scaling followed by a translation of the form (the positions are abbreviated now with their first letter):

$$C_V=ST=\begin{bmatrix}\frac{2}{r-l} & 0 & 0 & 0\\ 0 & \frac{2}{t-b} & 0 & 0\\ 0 & 0 & \frac{2}{f-n} & 0\\ 0 & 0 & 0 & 1\end{bmatrix}\begin{bmatrix}1 & 0 & 0 & -\frac{l+r}{2}\\ 0 & 1 & 0 & -\frac{t+b}{2}\\ 0 & 0 & -1 & -\frac{f+n}{2}\\ 0 & 0 & 0 & 1\end{bmatrix} \tag{8.4.55}$$

As illustrated in the figure below:

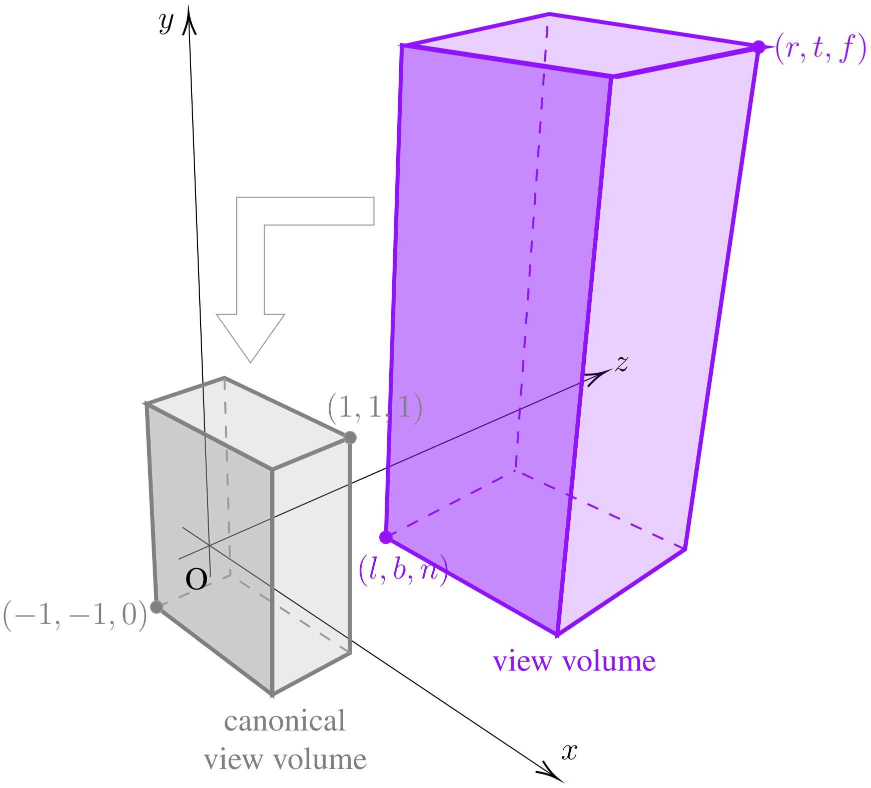

Figure 8.123: **Canonical transformation for orthogonal projection**

If the origin of the matrix C_V is not obvious here are the details to get it:

The easiest approach may be to consider each of the three axes separately, and compute how to map points along that axis from the original view volume into the canonical view volume. We begin with the x-coordinate. A point within our view volume will have an x-coordinate on the range $[l,r]$, and we want to transform it to the range $[-1,+1]$!

So first we see that we have:

$$l\leq x\leq r \tag{8.4.56}$$

Now, in preparation to scale the range down to the size we want, we subtract l from all terms to produce a zero on the left-hand side. Another approach we could take here would be to translate the range so that it centers on zero, rather than having one of its endpoints at zero, but the algebra is a bit neater this way, so we will do it like this for the sake of readability:

$$0\leq x-l\leq r-l \tag{8.4.57}$$

Now that one end of our range is positioned at zero, we can scale it down to the size we want. We want the range of x-values to be two units wide, from $+1$ to -1, so we multiply through by $2/(r-l)$. Notice that $r-l$ is the width of our view volume and is thus always a positive number, so we don't have to worry about the inequalities changing directions:

$$0 \leq \frac{2x-2l}{r-l} \leq 2 \tag{8.4.58}$$

Next, we subtract one from all terms to produce our desired range of $[-1,+1]$:

$$-1 \leq \frac{2x-2l}{r-l} - 1 \leq +1 \tag{8.4.59}$$

A bit of basic algebra allows us to write the center term as a single fraction:

$$-1 \leq \frac{2x-r-l}{r-l} - 1 \leq +1 \tag{8.4.60}$$

Finally, we split the center term into two fractions so that it takes the form $px+q$. For this we need to group our terms this way so that the equations we derive can be easily translated into matrix form:

$$-1 \leq \frac{2x}{r-l} - \frac{r+l}{r-} \leq +1 \tag{8.4.61}$$

The center term of this inequality now gives us the equation we need to transform x into the canonical view volume:

$$x' = \frac{2x}{r-l} - \frac{r+l}{r-l} \tag{8.4.62}$$

The steps required to obtain a formula for y are exactly the same. We just have to substitute y for x, t for r, and b for l. So rather than repeat them here, we will just show the result:

$$y' = \frac{2y}{t-b} - \frac{t+b}{t-b} \tag{8.4.63}$$

Finally, we need to derive a relation for z. It's a little different in this case because we are mapping z to the range $[0,+1]$ rather than $[-1,+1]$, but this should look very familiar. Here our starting condition, a z-coordinate on the range $[n,f]$:

$$n \leq z \leq f \tag{8.4.64}$$

We subtract n from all terms so the lower end of the range is positioned at zero:

$$0 \leq z-n \leq f-n \tag{8.4.65}$$

And now, all that's left is to divide through by $f-n$ to produce a final range of $[0,1]$. As before, we notice that $f-n$ indicates the depth of our viewing volume and thus will never be negative:

$$0 \leq \frac{z-n}{f-n} \leq 1 \tag{8.4.66}$$

Finally, we split this into two fractions so it takes the form $pz+q$:

$$0 \leq \frac{z}{f-n} - \frac{n}{f-n} \leq 1 \tag{8.4.67}$$

This gives us our formula for transforming z:

$$z' = \frac{z}{f-n} - \frac{n}{f-n} \tag{8.4.68}$$

Now, we are ready to write our centering orthographic projection matrix. To recap our work thus far, here are the three projection equations we have derived:

Once the canonical volume obtained we apply for example the simple orthographic projection onto the plane $z=0$ that is intuitively defined by the following matrix:

$$P_{xy} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{8.4.69}$$

For each point (x,y,z), the transformed point would be:

$$P_{xy} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} x \\ y \\ 0 \end{pmatrix} \tag{8.4.70}$$

Often, it is more useful to use homogeneous coordinates. The transformation above can be represented for homogeneous coordinates as:

$$P_{xy} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{8.4.71}$$

For each homogeneous vector (x,y,z), the transformed vector will be obviously:

$$P_{xy} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \begin{pmatrix} x \\ y \\ 0 \end{pmatrix} \tag{8.4.72}$$

Although this is the most used method in the industry on paper (or screen), however, it has a drawback: the real effect of depth is lost entirely and this is why orthogonal projection is often accompanied of an isometric projection view of the object of interest.

8.4.3 Spherical projections

Spherical projections is an important field in engineering topography and geography (and therefore navigation). As far as we know there is not far from more than 200 various techniques of spherical projection.

Indeed, it is impossible to render paths on a sphere onto a flat surface in such a way that all distances remain the same. In drawing a map of a sphere, therefore, some compromises must be made. Most maps adopt one of two possible strategies that areas are preserved or that angles are preserved. Stereographic projection (i.e. projection on a plane) is one way of making maps, and it preserves angles. It has been used since ancient times for this purpose, and its basic geometrical properties were known even then.

We will focus in this textbook only on the most known spherical projections and also without detailing the problems of projecting images from a sphere to a plane when the number of points (pixels) is not infinite...

For example here is a summary of some well known spherical projections[6]:

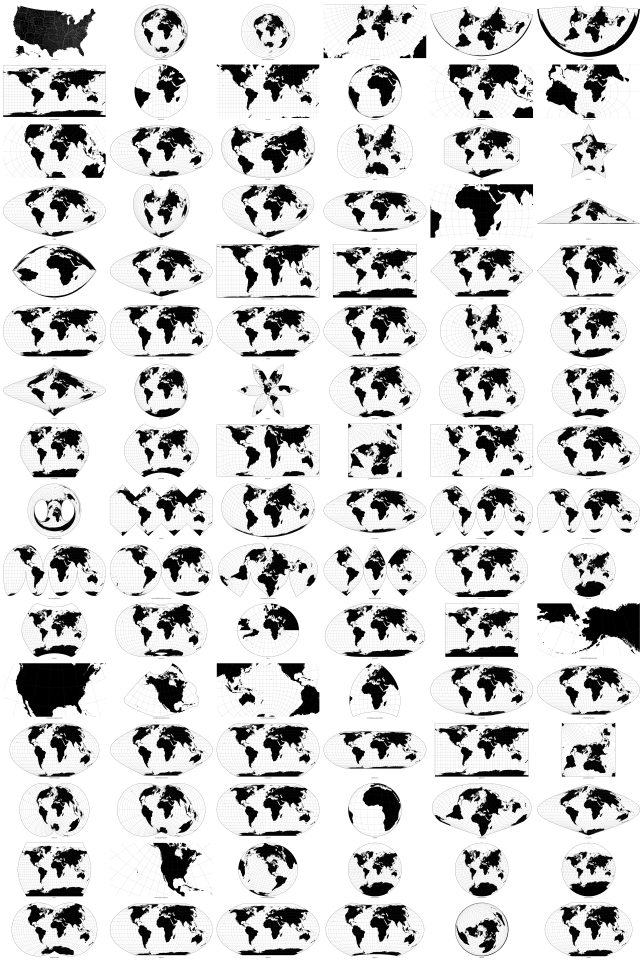

Figure 8.124: Various spherical and cylindrical projections like Mercator, Gall-Peters, Mollweide, Robinson, etc. (author: Mike Bostock)

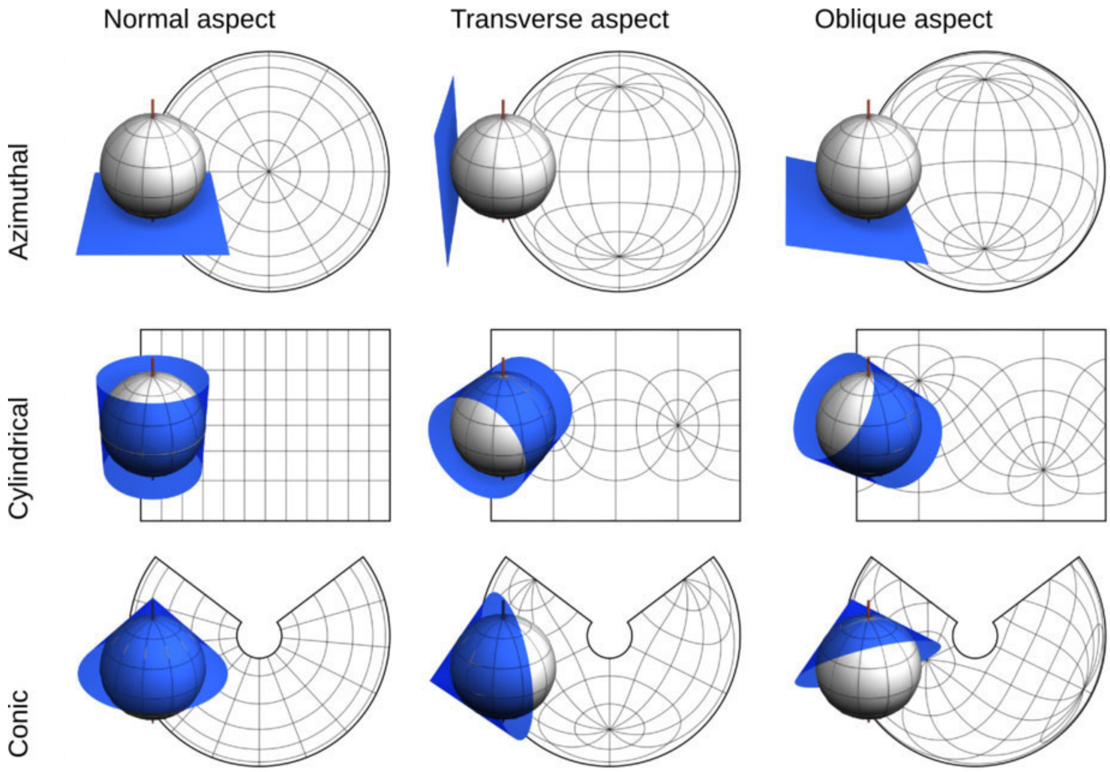
---

[6] The choice of the projection used in school depends mainly on the country government as some projections give more importance to some countries than others... But anyway any student can now see an Earth sphere (globe) in its class and this is the only totally conform existing projection!

Or with a more detailed idea of each technique and its corresponding name:



Normal aspect
Transverse aspect
Oblique aspect
Azimuthal
Cylindrical
Conic

Figure 8.125: Technical view of various spherical projections techniques

Remark

An exhaustive list of spherical projections is given on the projection list web page of the Geocart software available here:

`https://www.mapthematics.com/ProjectionsList.php`

Obviously we could avoid all the issues of spherical projections by using in schools and on logo of corporations or governmental agencies (like some already do!) a "hemispherical map":

TABLEAU SPHÉROÏDAL DE LA TERRE

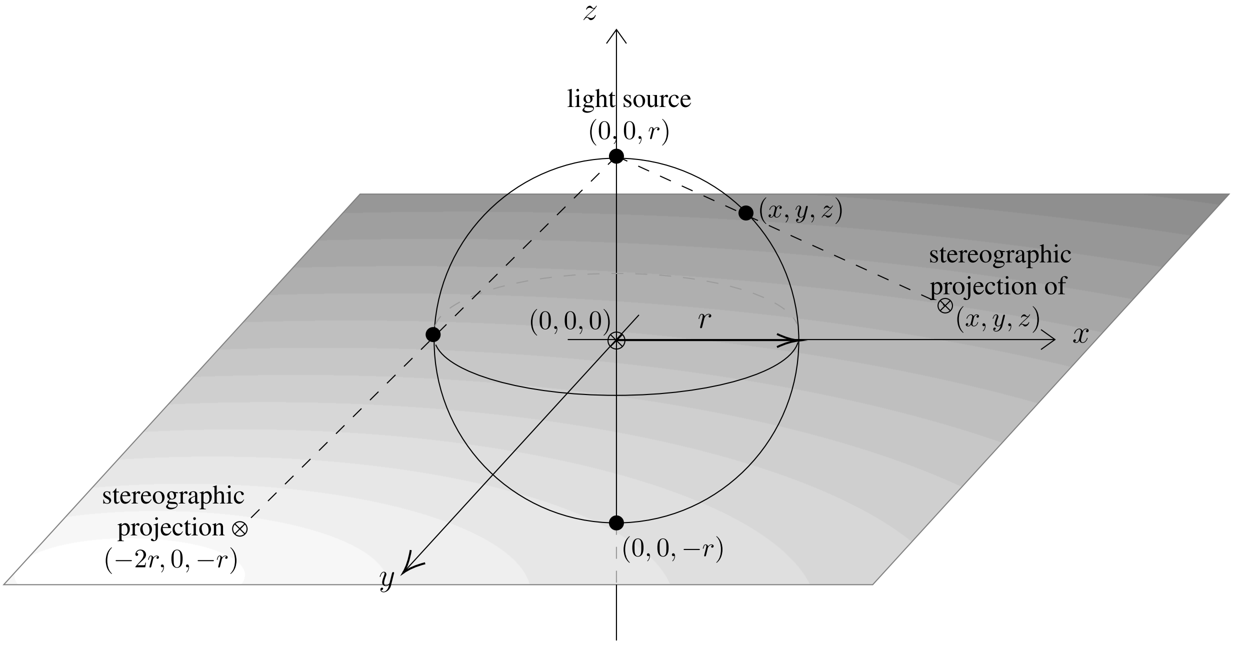
8.4.3.1 Stereographic projection

The "stereographic projection" (in the classical sense of the term), or more precisely the "azimuthal normal aspect projection", is one way of projecting the points that lie on a spherical surface onto a plane. Such projections are commonly used in Earth and space mapping where the geometry is often inherently spherical and needs to be displayed on a flat surface such as paper or a computer display. Any attempt to map a sphere onto a plane requires distortion, stereographic projections are no exception and indeed it is not an ideal approach if minimal distortion is desired.

A physical model of stereographic projections is to imagine a transparent sphere sitting on a plane. If we name the point at which the sphere touches the plane the "south pole" then we place a light source at the "north pole". Each ray from the light passes through a point on the and then strikes the plane, this is the stereographic projection of the point on the sphere.

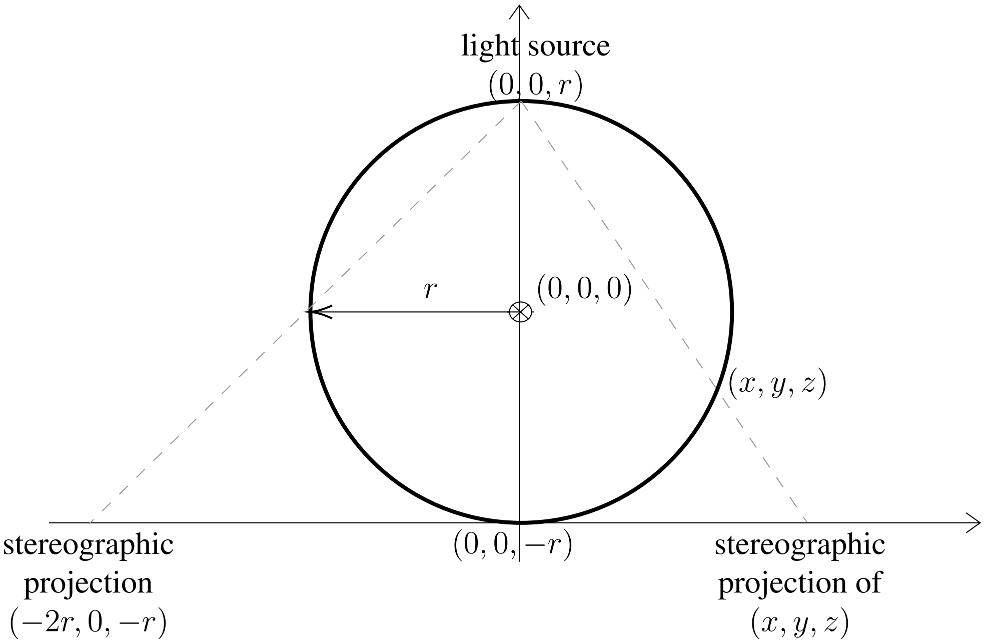
In order to derive the formula for the projection of a point (x,y,z) lying on the sphere assume the sphere is centered at the origin and is of radius r. The plane is all the points $z=-r$, and the light source is at point $(0,0,r)$. The cross section of this arrangement is shown below in what is commonly named a "Schlegel diagram" that looks like below in pseudo-perspective:



z
light source
$(0, 0, r)$
(x, y, z)
stereographic
projection of
(x, y, z)
$(0, 0, 0)$
r
x
stereographic
projection ⊗
$(-2r, 0, -r)$
y
$(0, 0, -r)$

Figure 8.126: **Schlegel diagram in pseudo-perspective (stereographic projection)**

and in front view:



light source
$(0, 0, r)$
r
$(0, 0, 0)$
(x, y, z)
stereographic
projection
$(-2r, 0, -r)$
$(0, 0, -r)$
stereographic
projection of
(x, y, z)

Figure 8.127: **Schlegel diagram in front view**

As we can see above the projection of $(0,0,r)$ gives obviously $(0,0,-r)$ and using Thales's theorem (or "intercept theorem") as proved in the section of Euclidean Geometry (see page 2610) we have immediately that the projection of $(-r,0,0)$ is $(-2r,0,r)$.

Let us consider now the equation of the line from $P_1=(0,0,r)$ through a point $P_2=(x,y,z)$

on the sphere. Therefore we have for the projected point P:

$$\vec{P} = \vec{P}_1 + a(\vec{P}_1 - \vec{P}_2) \tag{8.4.73}$$

Solving this for a for the z component yields:

$$-r = r + a(z - r) \tag{8.4.74}$$

or:

$$a = \frac{2r}{r - z} \tag{8.4.75}$$

Finally:

$$\boxed{\begin{pmatrix} x_p \\ y_p \\ z_p \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ r \end{pmatrix} + \frac{2r}{r-z}\begin{pmatrix} x \\ y \\ z - r \end{pmatrix} = \begin{pmatrix} \dfrac{2rx}{r-z} \\ \dfrac{2ry}{r-z} \\ -r \end{pmatrix}} \tag{8.4.76}$$

Notice that:

- The South pole is at the center of the projected points
- Lines of latitude project to concentric circles about $(0, 0, -r)$
- Lines of longitude project to rays from the point $(0, 0, -r)$
- There is little distortion near the South pole
- The equation project to a circle of radius $2r$
- The distortion increases the closer one gets to the north pole finally becoming infinite at the north pole
- As we can see in the image below, angles are preserved (since latitude and longitude are still perpendicular on the projected plane)

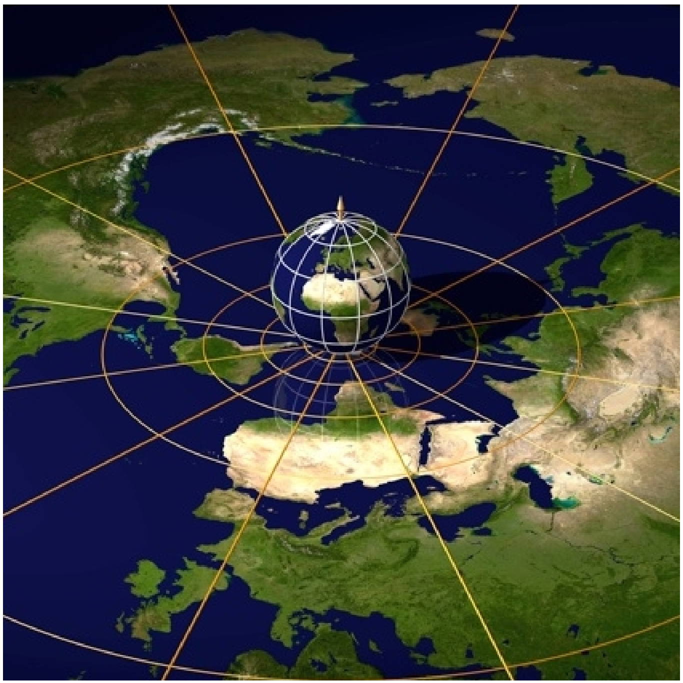


Figure 8.128: **Earth's stereographic projection (source: ?)**

Some author put the origin of the frame at the center of the sphere. Therefore the previous relations becomes:

$$\vec{P}=\begin{pmatrix}\dfrac{2rx}{r-z}\\\dfrac{2ry}{r-z}\\0\end{pmatrix}\tag{8.4.77}$$

and take for radius $r=1$. Then we have:

$$\vec{P}=\begin{pmatrix}\dfrac{x}{1-z}\\\dfrac{y}{1-z}\\0\end{pmatrix}=\left(\frac{x}{1-z},\frac{y}{1-z},0\right)\tag{8.4.78}$$

And as we denote the components of the projected points by a,b,c instead of x,y,z, we get:

$$\vec{P}=\left(\frac{a}{1-c},\frac{b}{1-c},0\right)\tag{8.4.79}$$

And as the last coordinate is always 0 we only write:

$$\vec{P}=\left(\frac{a}{1-c},\frac{b}{1-c}\right)\tag{8.4.80}$$

And when the projection plane is assimilated to the (complex) projection plane, then we get the relation that we can find most of time in books:

$$\boxed{P=\frac{a}{1-c}+\mathrm{i}\frac{b}{1-c}=\frac{a+\mathrm{i}b}{1-c}}\tag{8.4.81}$$

Theorem 8.19. The stereographic projection is a conformal projection (i.e. conserves the angles). That is to say:

If we consider the stereographic projection $\pi: S^2 \setminus \{\vec{e}_3\} \in \mathbb{R}^3$ as we have proved it, defined by:

$$\pi: (x,y,z)^T \Rightarrow \left(\frac{x}{1-z}, \frac{y}{1-z}, 0\right)^T \tag{8.4.82}$$

with $x^2+y^2+z^2=1$ and $\vec{e}_3=(0,0,1)^T$.

Given two paths φ and γ of type $\mathcal{C}^1$ on the sphere (that is to say two differentiable applications in which the derivative is continuous for recall...) such as (empirical choice):

$$\varphi(0)=\gamma(0) \tag{8.4.83}$$

and such that $\varphi(0)=\gamma(0)\neq\vec{e}_3$, we want to check if (we use the bracket notation for the dot product to not confuse it with the round symbol of function composition):

$$\frac{\langle(\pi\circ\varphi)'(0),(\pi\circ\gamma)'(0)\rangle}{||(\pi\circ\varphi)'(0)||\cdot||(\pi\circ\gamma)'(0)||}=\frac{\langle\varphi'(0),\gamma'(0)\rangle}{||\varphi'(0)||\cdot||\gamma'(0)||} \tag{8.4.84}$$

where $\varphi'(0)$ and $\gamma'(0)$ are the tangent vectors of φ and γ on point 0 and $(\pi\circ\varphi)'(0)$ and $(\pi\circ\gamma)'(0)$ are there corresponding tangent vectors on the projection plane.

Proof 8.19.1. To do the proof let start by developing the expressions $(\pi\circ\varphi)'(0)$ and $(\pi\circ\gamma)'(0)$. Let us write $\varphi=(\varphi_x,\varphi_y,\varphi_z)^T$. We have :

$$\pi\circ\varphi=\left(\frac{\varphi_x}{1-\varphi_z},\frac{\varphi_y}{1-\varphi_z}\right)^T \tag{8.4.85}$$

Let us simplify the denominator by putting:

$$\vec{u}=\vec{\varphi}-\vec{e} \tag{8.4.86}$$

Then we get:

$$\pi\circ\varphi=\left(-\frac{u_x}{u_z},-\frac{u_y}{u_z},0\right)^T \tag{8.4.87}$$

Hence:

$$\begin{aligned}(\pi\circ\varphi)'(0)&=\left(\frac{-u_x{}'(0)\cdot u_z(0)+u_x(0)\cdot u_z{}'(0)}{u_z(0)^2},\frac{-u_y{}'(0)\cdot u_z(0)+u_y(0)\cdot u_z{}'(0)}{u_z(0)^2},0\right)^T\\&=\frac{1}{u_z(0)}(-u_x{}'(0),-u_y{}'(0),0)^T+\frac{u_z{}'(0)}{u_z(0)^2}(u_x(0),u_y(0),0)^T\\&=-\frac{1}{u_z(0)}(u_x{}'(0),u_y{}'(0),u_z{}'(0))^T+\frac{u_z{}'(0)}{u_z(0)^2}(u_x(0),u_y(0),u_z(0))^T\\&=-\frac{1}{u_z(0)}\vec{u}'(0)+\frac{u_z{}'(0)}{u_z(0)^2}\vec{u}(0)\end{aligned} \tag{8.4.88}$$

And same, by putting:

$$\vec{v}=\vec{\gamma}-\vec{e}_3 \tag{8.4.89}$$

we get:

$$(\pi\circ\gamma)'(0)=-\frac{1}{v_z(0)}\vec{v}\,'(0)+\frac{v'_z(0)}{v_z(0)^2}\vec{v}(0) \tag{8.4.90}$$

Let us now develop $\langle(\phi\circ\varphi)'(0),(\phi\circ\gamma)'(0)\rangle$:

$$\begin{aligned}&\left\langle(\pi\circ\varphi)'(0),(\pi\circ\gamma)'(0)\right\rangle=\left\langle-\frac{1}{u_z\,(0)}u'\,(0)+\frac{u_z{}'\,(0)}{u_z(0)^2}u\,(0)\,,-\frac{1}{v_z\,(0)}v'\,(0)+\frac{v_z{}'\,(0)}{v_z(0)^2}v\,(0)\right\rangle\\&=\frac{1}{u_z\,(0)\,v_z\,(0)}\left\langle u'\,(0)\,,v'\,(0)\right\rangle\\&-\frac{v_z{}'\,(0)}{u_z\,(0)\,v_z(0)^2}\left\langle u'\,(0)\,,v\,(0)\right\rangle-\frac{u_z{}'\,(0)}{u_z(0)^2v_z\,(0)}\left\langle u\,(0)\,,v'\,(0)\right\rangle+\frac{u_z{}'\,(0)\,v_z{}'\,(0)}{u_z(0)^2\,v_z(0)^2}\left\langle u\,(0)\,,v\,(0)\right\rangle\end{aligned} \tag{8.4.91}$$

The change of variables takes us immediately to:

$$\varphi(0)=\gamma(0)\Leftrightarrow u(0)=v(0) \tag{8.4.92}$$

Therefore:

$$\begin{aligned}&\left\langle(\pi\circ\varphi)'(0),(\pi\circ\gamma)'(0)\right\rangle=\\&=\frac{1}{u_z(0)^2}\left\langle u'\,(0)\,,v'\,(0)\right\rangle-\frac{v_z{}'\,(0)}{u_z(0)^3}\left\langle u'\,(0)\,,u\,(0)\right\rangle-\frac{u_z{}'\,(0)}{u_z(0)^3}\left\langle v\,(0)\,,v'\,(0)\right\rangle+\frac{u_z{}'\,(0)\,v_z{}'\,(0)}{u_z(0)^4}\left\langle u\,(0)\,,u\,(0)\right\rangle\end{aligned} \tag{8.4.93}$$

As by construction:

$$\langle\varphi,\varphi'\rangle=0 \tag{8.4.94}$$

and that we also have:

$$\langle u,u'\rangle=\langle\varphi-\vec{e}_3,\varphi'\rangle=-\langle\vec{e}_3,\varphi'\rangle=-\varphi'_z=-u'_z \tag{8.4.95}$$

and identically:

$$\langle v,v'\rangle=-v'_z \tag{8.4.96}$$

then the above dot product becomes:

$$\begin{aligned}&\left\langle(\pi\circ\varphi)'(0),(\pi\circ\gamma)'(0)\right\rangle\\&=\frac{1}{u_z(0)^2}\left\langle u'\,(0)\,,v'\,(0)\right\rangle+2\frac{v_z{}'\,(0)\,u_z{}'\,(0)}{u_z(0)^3}+\frac{u_z{}'\,(0)\,v_z{}'\,(0)}{u_z(0)^4}\left\langle u\,(0)\,,u\,(0)\right\rangle\\&=\frac{1}{u_z(0)^2}\left\langle u'\,(0)\,,v'\,(0)\right\rangle+\frac{u_z{}'\,(0)\,v_z{}'\,(0)}{u_z(0)^4}\left(\left\langle u\,(0)\,,u\,(0)\right\rangle+2u_z\,(0)\right)\end{aligned} \tag{8.4.97}$$

But:

$$\begin{aligned}\langle u(0),u(0)\rangle+2u_z(0)&=\langle u(0),u(0)\rangle+2\langle u(0),e_3\rangle=\langle u(0),u(0)+2e_3\rangle\\&=\langle\varphi(0)-e_3,\varphi(0)+e_3\rangle=\varphi_x^2+\varphi_y^2+(\varphi_z-1)(\varphi_z+1)\\&=\varphi_x^2+\varphi_y^2+\varphi_z^2-1^2=1-1=0\end{aligned}\tag{8.4.98}$$

since by construction $\varphi_x^2+\varphi_y^2+\varphi_z^2=1$.

So finally our numerator is given by:

$$\left\langle(\pi\circ\varphi)'(0),(\pi\circ\gamma)'(0)\right\rangle=\frac{1}{u_z(0)^2}\langle u'(0),v'(0)\rangle=\frac{1}{(\varphi_z(0)-1)^2}\langle\varphi'(0),\gamma'(0)\rangle\tag{8.4.99}$$

Let us now calculate the first term of the denominator $||(\pi\circ\varphi)'(0)||$:

$$\begin{aligned}\left\|(\pi\circ\varphi)'(0)\right\|^2&=\left\langle-\frac{1}{u_z(0)}u'(0)+\frac{u_z{}'(0)}{u_z(0)^2}u(0),-\frac{1}{u_z(0)}u'(0)+\frac{u_z{}'(0)}{u_z(0)^2}u(0)\right\rangle\\&=\frac{1}{u_z(0)^2}\langle u'(0),u'(0)\rangle+2\frac{u_z{}'(0)^2}{u_z(0)^3}+\frac{u_z{}'(0)^2}{u_z(0)^4}\langle u(0),u(0)\rangle\end{aligned}\tag{8.4.100}$$

as for recall (see proof just before) $\langle u,u'\rangle=-u'_z$.

But we also have:

$$\begin{aligned}\langle u,u\rangle&=\langle\varphi-\vec{e}_3,\varphi-\vec{e}_3\rangle=\varphi_x^2+\varphi_y^2+(\varphi_z-1)^2\\&=\varphi_x^2+\varphi_y^2+\varphi_z^2-2\varphi_z+1=1-2\varphi_z+1=2(1-\varphi_z)=-2u_z\end{aligned}\tag{8.4.101}$$

Therefore the previous expressions becomes:

$$\left\|(\pi\circ\varphi)'(0)\right\|^2=\frac{1}{u_z(0)^2}\langle u'(0),u'(0)\rangle=\frac{1}{(\varphi_z(0)-1)^2}\langle\varphi'(0),\varphi'(0)\rangle\tag{8.4.102}$$

Similarly:

$$\left\|(\pi\circ\gamma)'(0)\right\|^2=\frac{1}{(\gamma_z(0)-1)^2}\langle\gamma'(0),\gamma'(0)\rangle\tag{8.4.103}$$

To finish, we put:

$$\begin{aligned}\left\langle(\pi\circ\varphi)'(0),(\pi\circ\gamma)'(0)\right\rangle&=\frac{1}{(\varphi_z(0)-1)^2}\langle\varphi'(0),\gamma'(0)\rangle\\\left\|(\pi\circ\varphi)'(0)\right\|^2&=\frac{1}{(\varphi_z(0)-1)^2}\langle\varphi'(0),\varphi'(0)\rangle\\\left\|(\pi\circ\gamma)'(0)\right\|^2&=\frac{1}{(\gamma_z(0)-1)^2}\langle\gamma'(0),\gamma'(0)\rangle\end{aligned}\tag{8.4.104}$$

inside:

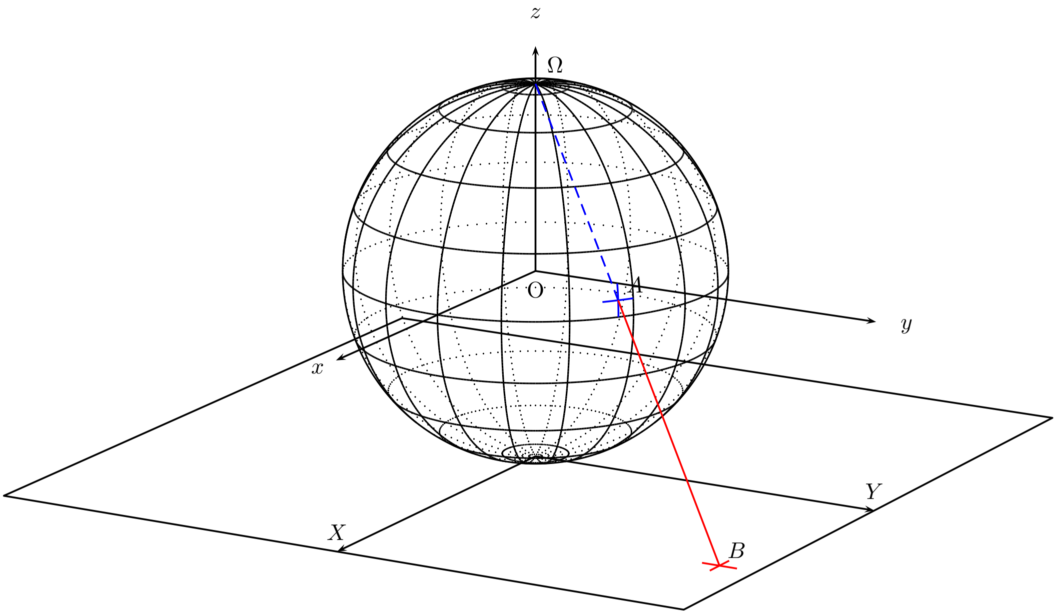
$$\frac{\langle(\pi\circ\varphi)'(0),(\pi\circ\gamma)'(0)\rangle}{||(\pi\circ\varphi)'(0)||\cdot||(\pi\circ\gamma)'(0)||}\tag{8.4.105}$$

and we get:

$$\frac{\left\langle(\pi\circ\varphi)'(0),(\pi\circ\gamma)'(0)\right\rangle}{\left\|(\pi\circ\varphi)'(0)\right\|\cdot\left\|(\pi\circ\gamma)'(0)\right\|}=\frac{\langle\varphi'(0),\gamma'(0)\rangle}{\sqrt{\langle\varphi'(0),\varphi'(0)\rangle}\sqrt{\langle\gamma'(0),\gamma'(0)\rangle}}=\frac{\langle\varphi'(0),\gamma'(0)\rangle}{\|\varphi'(0)\|\cdot\|\gamma'(0)\|}\tag{8.4.106}$$

■ Q.E.D.

Many people need in 3D softwares to map an image (a flat one) on a sphere. How do software do the inverse of a stereographic projection? To see that, let us consider first the following illustration made by Manuel Luque:



In the figure above we have first:

$$\text{O}=\begin{pmatrix}0\\0\\0\end{pmatrix}\quad \Omega=\begin{pmatrix}0\\0\\1\end{pmatrix}\quad A=\begin{pmatrix}x\\y\\z\end{pmatrix} \tag{8.4.107}$$

and we also have:

$$x^2+y^2+z^2=1 \tag{8.4.108}$$

and we also have:

$$B=\begin{pmatrix}X\\Y\\-1\end{pmatrix}\quad \overrightarrow{\Omega A}=\begin{pmatrix}x\\y\\z-1\end{pmatrix}\quad \overrightarrow{\Omega B}=\begin{pmatrix}X\\Y\\-2\end{pmatrix} \tag{8.4.109}$$

and trivially:

$$\overrightarrow{\Omega A}=k\overrightarrow{\Omega B}\Longleftrightarrow\begin{pmatrix}x\\y\\z-1\end{pmatrix}=k\begin{pmatrix}X\\Y\\-2\end{pmatrix} \tag{8.4.110}$$

The problem posed is the following: we give ourself the coordinates of a point B of the plane $z=-1$, we must deduce the coordinates of the point A of the sphere $x=f(X,Y);y=g(X,Y);z=h(X,Y)$.

First we have easily:

$$\begin{cases} x = kX \\ y = kY \\ 1 - z = 2k \end{cases} \Longrightarrow \begin{array}{l} x^2 + y^2 = k^2\left(X^2 + Y^2\right) \\ k = \frac{1-z}{2} \end{array} \tag{8.4.111}$$

Knowing that $x^2 + y^2 = 1 - z^2$ we get by replacing:

$$1 - z^2 = \frac{(1-z)^2}{4}\left(X^2 + Y^2\right) \Longrightarrow 4(1+z) = (1-z)\left(X^2 + Y^2\right) \tag{8.4.112}$$

Therefore:

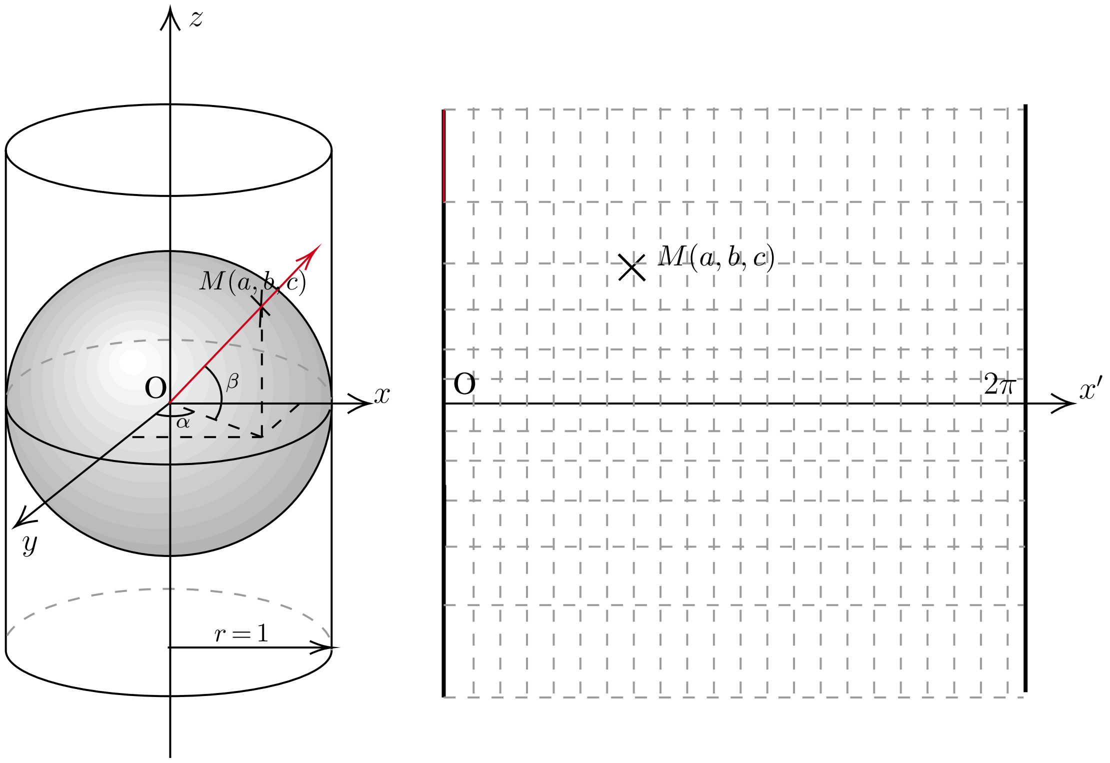
$$z = \frac{X^2 + Y^2 - 4}{X^2 + Y^2 + 4} \tag{8.4.113}$$

Doing the same for the other two coordinates, we get:

$$\begin{cases} x = \frac{4X}{X^2+Y^2+4} \\ y = \frac{4Y}{X^2+Y^2+4} \\ z = \frac{X^2+Y^2-4}{X^2+Y^2+4} \end{cases} \tag{8.4.114}$$

8.4.3.2 Cylindrical projection

The "cylindrical projection" (in the classical sense of the term) or more precisely named the "cylindrical normal aspect projection", is one where lines of latitude are projected to equally spaced parallel lines and lines of longitude are projected onto not necessarily equally spaced parallel lines. The figure below illustrates the basic projection, a line is projected from the center of the sphere through each point on the sphere until it intersects:



As we can see from the above figure it is quite obvious first that:

$$\tan(\beta)=\frac{z'}{r}=\frac{z'}{1}\Rightarrow z'=\tan(\beta)=\tan\left(\arctan\left(\frac{c}{\sqrt{a^2+b^2}}\right)\right)=\frac{c}{\sqrt{a^2+b^2}} \tag{8.4.115}$$

and for x' we have obviously:

$$x'=\alpha=\operatorname{sgn}(x)\arccos\left(\frac{b}{\sqrt{a^2+b^2}}\right) \tag{8.4.116}$$

with for recall:

$$\operatorname{sgn}(x)=\begin{cases}-1 & x<0\\ 0 & x=0\\ +1 & x>0\end{cases} \tag{8.4.117}$$

So finally:

$$\boxed{\begin{aligned}&x'=\alpha=\operatorname{sgn}(x)\arccos\left(\frac{b}{\sqrt{a^2+b^2}}\right)\\&z'=\tan(\beta)=\frac{c}{\sqrt{a^2+b^2}}\end{aligned}} \tag{8.4.118}$$

Schematically the steps of construction are the following:

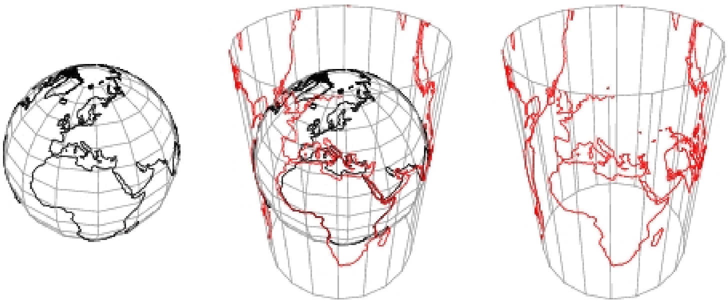


Figure 8.129: **Earth's cylindrical projection**

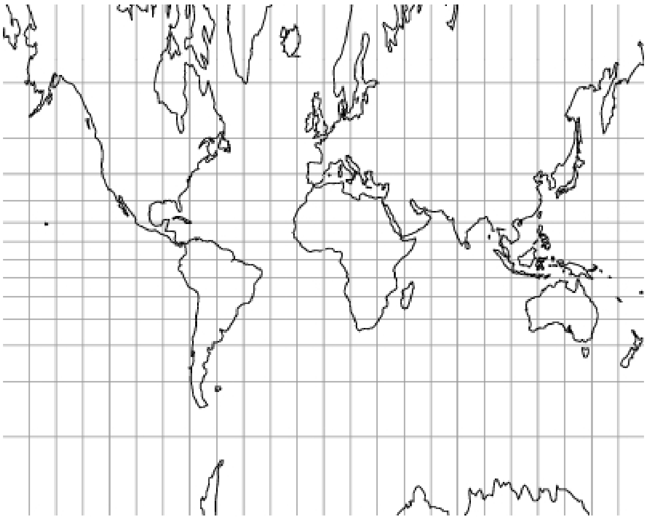
which results in:



It should be quite obvious (without proof) that this projection does not conserve the areas, but conserve the angles!

8.4.3.3 Mercator projection

A "Mercator projection" is similar in appearance to a cylindrical projection but has a different distortion in the spacing of the lines of longitude (the same idea applies for the so named "Gall stereographic projection" or "Gall–Peters projection" that we will not introduce in this textbook). The Mercator projection is still in the beginning of the 121st century the most common projection used in mapping the Earth onto a flat surface (it advantages, using human bias, the countries habited by white color christian people...).

Like the cylindrical projection North and South are always vertical, we cannot therefore represent the poles because the mathematics have an infinity singularity there.

The result of such a projection is:

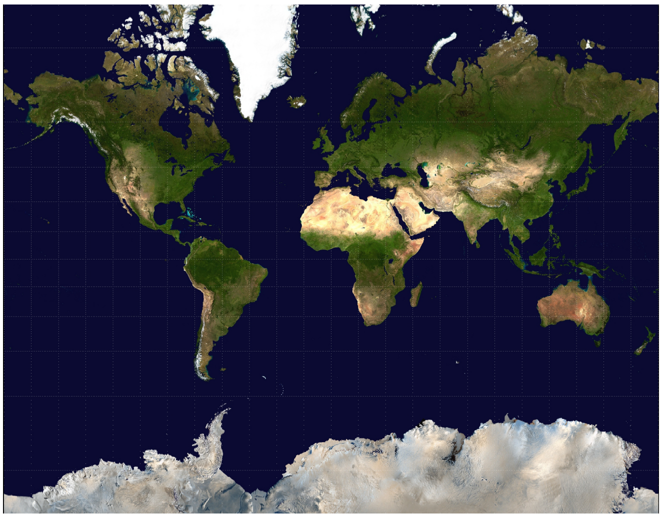


Figure 8.130: **Earth's Mercator projection**

The Mercator map projection with the true sizes and shapes of the countries overlaid:

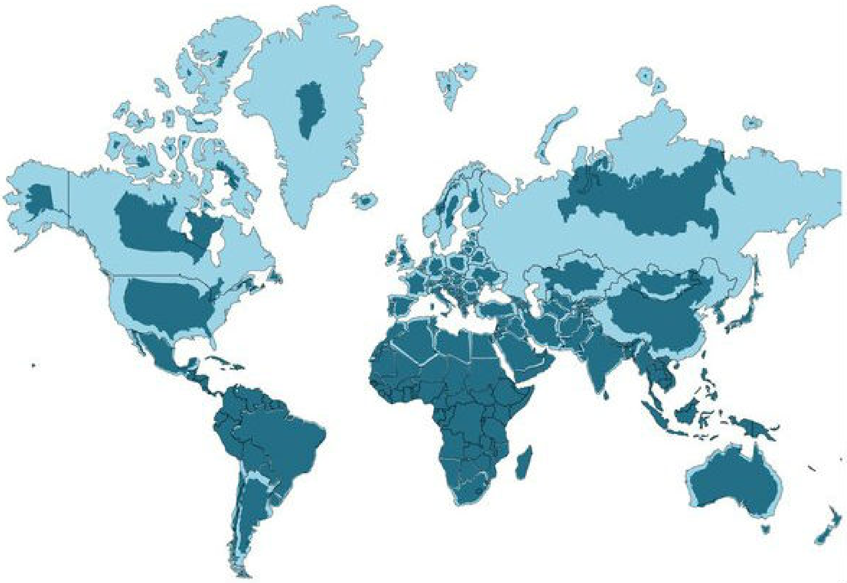

Figure 8.131: **Mercator map projection with the true sizes and shapes of the countries overlaid (author: Neil Kaye)**

As we have seen previously, the cylindrical map projection is specified by formula linking the geographic coordinates of latitude β and longitude α to Cartesian coordinates on the map with origin on the equator and x-axis along the equator. By construction, all points on the same meridian lie on the same generator of the cylinder at a constant value of x, but the distance y along the generator (measured from the equator) is an arbitrary function of latitude, $y(\beta)$. In general this function does not describe the geometrical projection (as of light rays onto a screen) from the center of the globe to the cylinder, which is only one of an unlimited number of ways to conceptually project a cylindrical map.

Since the cylinder is tangential to the globe of radius R at the equator, the scale factor between globe and cylinder is obviously unity on the equator but nowhere else. In particular since the radius of a parallel, or circle of latitude, is $R\cos(\beta)$, the corresponding parallel on the map must have been stretched by a factor of:

$$\frac{R}{R\cos(\beta)}=\frac{1}{\cos(\beta)}=\sec(\beta) \tag{8.4.119}$$

This scale factor on the parallel is conventionally denoted by k and the corresponding scale factor on the meridian is denoted by h.

The relations between $y(\beta)$ and properties of the projection, such as the transformation of angles and the variation in scale, follow from the geometry of corresponding small elements on the globe and map. The figure below shows a point P at latitude β and longitude α on the globe and a nearby point Q at latitude $\phi+\delta\phi$ and longitude $\alpha+\delta\alpha$. The vertical segments $\overset{\frown}{PK}$ and $\overset{\frown}{MQ}$ are arcs of meridians of length $R\delta\beta$ (see the proof in the section Trigonometry). The horizontal segment $\overset{\frown}{PM}$ and $\overset{\frown}{KQ}$ are arcs of parallels of length $R\cos(\beta)\delta\alpha$ (still following from the same proof of the section Trigonometry). The corresponding points on the projection define a rectangle of width δx and height δy:

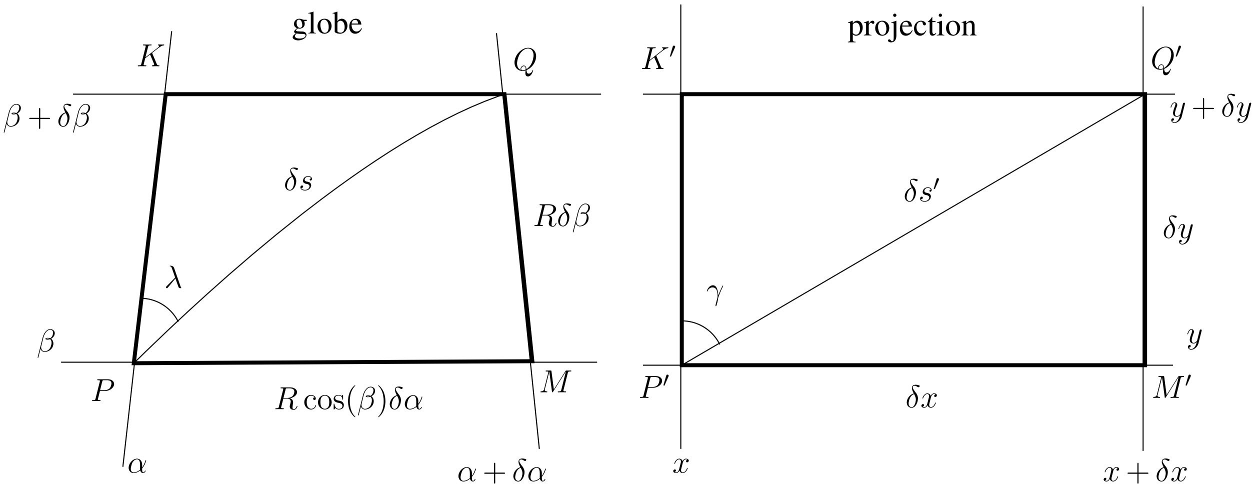

Figure 8.132: **Mercator projection function construction**

For small elements, the angle $\widehat{PKQ}$ is approximately a right angle and therefore:

$$\tan(\lambda)\cong\frac{R\cos(\beta)\alpha}{R\delta\beta}=\frac{\cos(\beta)\delta\alpha}{\delta\beta} \qquad \tan(\gamma)\cong\frac{\delta x}{\delta y} \tag{8.4.120}$$

The previously mentioned scaling factors from globe to cylinder are given by:

- Parallel scale factor:

$$k(\alpha)=\frac{\overline{P'M'}}{\overline{PM}}=\frac{\delta x}{R\cos(\beta)\delta\alpha} \tag{8.4.121}$$

- Meridian scale factor:

$$k(\alpha)=\frac{\overline{P'K'}}{\overline{PK}}=\frac{\delta y}{R\delta\alpha} \tag{8.4.122}$$

Consider now that the projection plane we take has for x-coordinates the range $[-\pi R, +\pi R]$ (the whole being then equal to $2\pi R$). Then for every meridian:

$$x = R(\alpha - \alpha_0) \tag{8.4.123}$$

Indeed, it is easy to see that if $(\alpha - \alpha_0) = 2\pi$ we have well $x = 2\pi r$ when we take time $\alpha_0 = 0$. But in the general case we have obviously:

$$\delta x = R\delta\alpha \tag{8.4.124}$$

Therefore we can write:

$$\tan(\gamma) \cong \frac{\delta x}{\delta y} = \frac{R\delta\alpha}{\delta y} = \frac{R\dfrac{\tan(\lambda)\delta\beta}{\cos(\beta)}}{\delta y} = \frac{R\sec(\beta)}{\delta y/\delta\beta}\tan(\lambda) \cong \frac{R\sec(\beta)}{y'(\beta)}\tan(\lambda) \tag{8.4.125}$$

Where we have considered that:

$$\frac{\delta y}{\delta \beta} \cong \frac{\mathrm{d}y}{\mathrm{d}\beta} = y'(\beta) \tag{8.4.126}$$

The choice of the function $y(\beta)$ for the Mercator projection is determined by the demand that the projection to be conformal[7] (!), a condition which can be defined as the equality of angles as proved earlier above. The condition that a sailing course of constant azimuth λ on the globe is mapped into a constant grid bearing γ on the map. Setting $\lambda = \gamma$ in:

$$\tan(\gamma) \cong \frac{\sec(\beta)}{y'(\beta)}\tan(\lambda) \tag{8.4.127}$$

gives immediately after rearranging:

$$y'(\beta) = R\sec(\beta) \tag{8.4.128}$$

with $y(0) = 0$, by using the primitives proved in the section of Differential and Integral Calculus (see page 1534) we have immediately:

$$y(\beta) = \ln\left(\left|\tan\left(\frac{\beta}{2} + \frac{\pi}{4}\right)\right|\right) \tag{8.4.129}$$

So finally:

$$\boxed{\begin{aligned} &x = (\alpha - \alpha_0) \\ &y = \ln\left(\left|\tan\left(\frac{\beta}{2} + \frac{\pi}{4}\right)\right|\right) \end{aligned}} \tag{8.4.130}$$

In the first equation α_0 is the longitude of an arbitrary central meridian usually, but not always, that of Greenwich (i.e., zero).

---

[7] Very useful for navigators as a few centuries ago they were using mainly magnetic compass (and also star position techniques for double check...) to drive their boat. With a conformal map, you just draw a straight line between two points of the map (departure and arrival points), you measure the angle relatively to the vertical grid-lines of the map and after you just have to keep in mind while driving the boat to conserve this angle with the compass relatively to the North direction to reach your target.

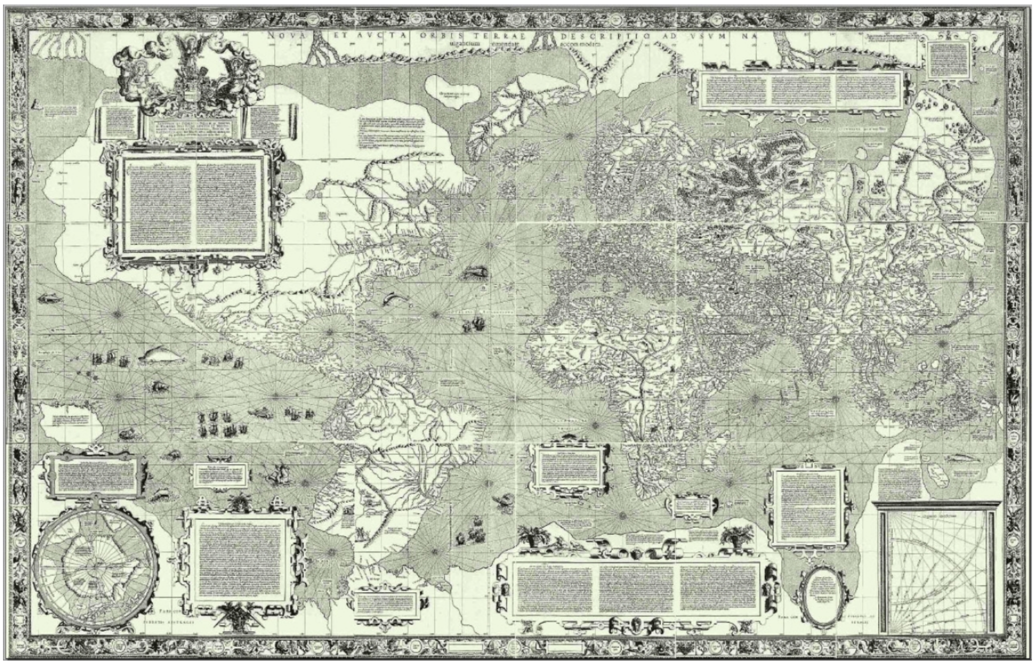

Figure 8.133: **Mercator world map as seen in 11569 (holocene calendar)... (source: Wikipedia)**

8.4.3.4 Lambert's equivalent projection (Peters projection)

The idea behind the "Lambert's equivalent projection", also named "Lambert's cylindrical equal-area projection" or sometimes "Peter's projection" (must not be confused with "Gall's-Peter projection"!), is quite easy as illustrated in the figure below:

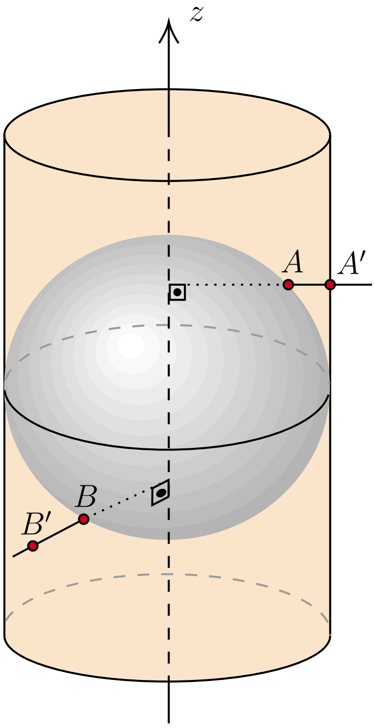

Figure 8.134: **Lambert's equivalent projection (or Lambert's equal area projection)**

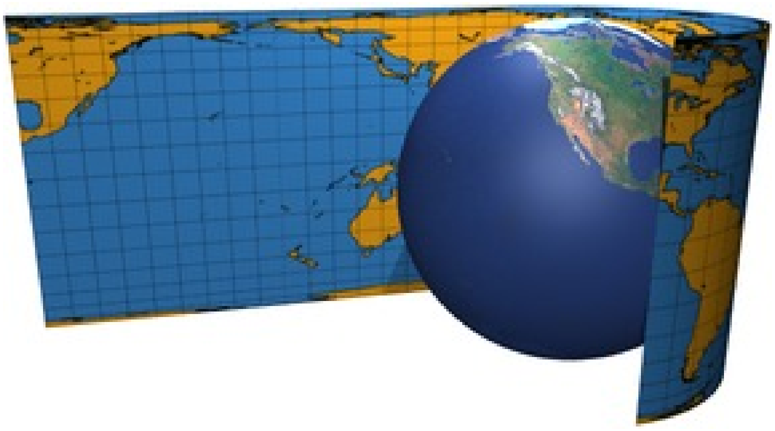
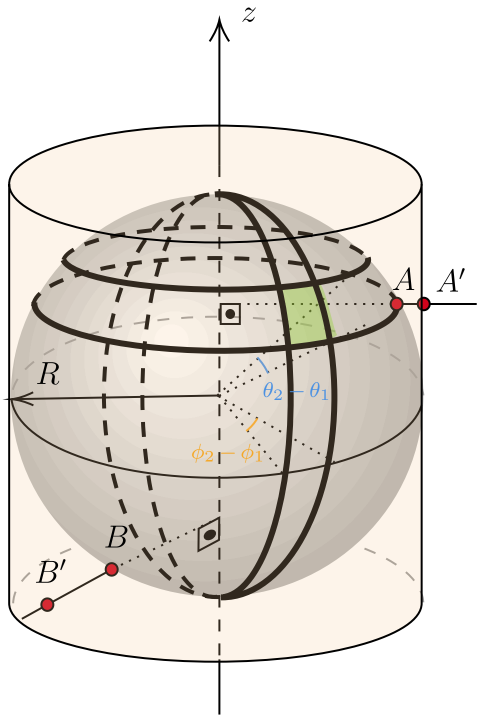
Suppose we have a terrestrial globe as visible above. It is enough to wrap a sheet of paper around the globe as in the figure above and to project horizontally each point of the sphere on the cylinder. For that, if A is a point of the sphere, we take the line passing through A and perpendicular to the axis of the poles This line intersects the cylinder at A': the point A' represents the point A on the map.

Or more explicitly:



Now using the following figure, let us prove that the Lambert's cylindrical projection conserve the areas (that's its huge advantage in comparison of the Mercator map that biases the areas of countries), in other words it is a projection named "authalic projection:



For this proof, we will look to a small area of the sphere delimited by the parallels of latitude θ_1 and θ_2 and of the meridians of longitude ϕ_1 and ϕ_2. We will denote by R the radius of the sphere and we will assume that $\theta_2-\theta_1$ and $\phi_2-\phi_1$ are positive and small.

According to this assumption, the area of this region is that of a small rectangle (see figure above). At the latitude θ_1, the radius of the parallel is obviously $R\cos(\theta_1)$. Then by a simple rule of three, the length of the arc from angle $\phi_2 - \phi_1$ is equal to $R(\phi_2 - \phi_1)\cos(\theta_1)$, as the length of the area is the product or the radius by the angle in radian (see section Trigonometry page 2542).

What is now the height of this rectangle? As the meridian is a circle of radius R and that the height of the rectangle is given by angle $\theta_2 - \theta_1$, then this height is given approximately by $R(\theta_2 - \theta_1)$. Then the area of our small region is approximately equal to:

$$R^2(\theta_2 - \theta_1)(\phi_2 - \phi_1)\cos(\theta_1) \tag{8.4.131}$$

Let us calculate now the area of its projection on the cylinder. This projection is now a real rectangle. The parallel has been projected on a circle of radius R. As the corresponding angle has remained the same, that is $\phi_2 - \phi_1$, the width of the rectangle is $R(\phi_2 - \phi_1)$. For the height, the reader must notice that the tangent to the meridian at the latitude θ_1 make an angle of:

$$\frac{\pi}{2} - \theta_1 \tag{8.4.132}$$

with the horizontal. The projection on the vertical of a segment of length $R(\theta_2 - \theta_1)$ is then equal to:

$$R(\theta_2 - \theta_1)\sin\left(\frac{\pi}{2} - \theta_1\right) = R(\theta_2 - \theta_1)\cos(\theta_1) \tag{8.4.133}$$

The area on the map is then equal to:

$$R^2(\theta_2 - \theta_1)(\phi_2 - \phi_1)\cos(\theta_1) \tag{8.4.134}$$

Thus, the same area than that of the small area on the sphere. This finish the proof that Lambert's cylindrical projection conserves the area.

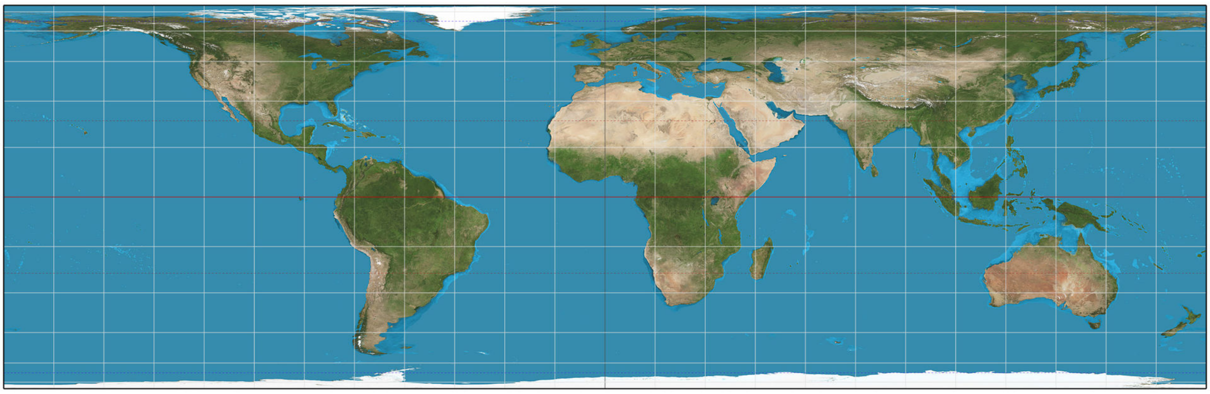


Figure 8.135: **Earth's Lambert projection (source: Wikipedia)**

8.4.3.5 Mollweide projection

The "Mollweide projection" is a very famous equal-area, pseudocylindrical map projection generally used for global maps of the world or night sky (it is also known as the "Babinet projection", "homalographic projection", "homolographic projection" and "elliptical projection"). The projection trades accuracy of angle and shape for accuracy of proportions in area, and as such is used where that property is needed, such as maps depicting global distributions.

The text that follows is entirely inspired from the paper [335] where the method is derived in details using three different proofs. Here we will focus on what seems to us the simplest of the three derivations that make sense.

Pseudocylindrical map projections have in common straight parallel lines of latitude and curved meridians. Until the 119th century (holocene calendar) the only pseudocylindrical projection with important properties was the sinusoidal or Sanson-Flamsteed. The sinusoidal has equally spaced parallels of latitude, true scale along parallels, and equivalency or equal-area. As a world map, it has disadvantage of high distortion at latitudes near the poles, especially those far from the central meridian:

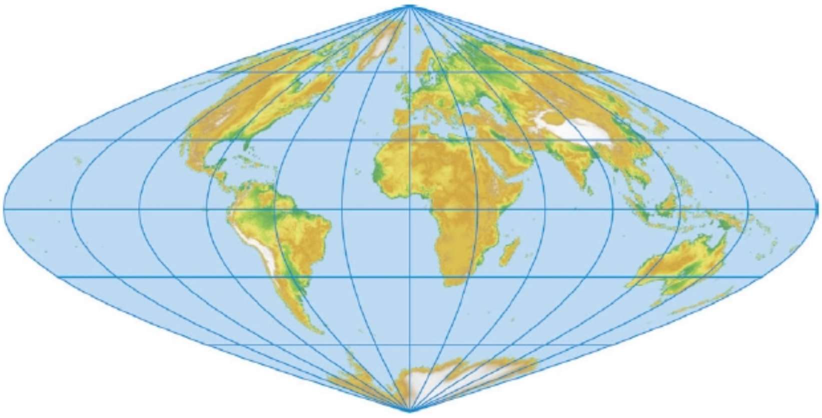

Figure 8.136: **Sansons or Sanson-Flamsteed or Sinuoidal projection**

In 11805 (holocene calendar), Mollweide announced an equal-area world map projection that is aesthetically more pleasing than the sinusoidal because the world is placed in an ellipse with axes in a ratio and all the meridians are equally spaced semi-ellipses. The Mollweide projection was the only new pseudocylindrical projection of the 119th century (holocene calendar) to receive much more than academic interest:

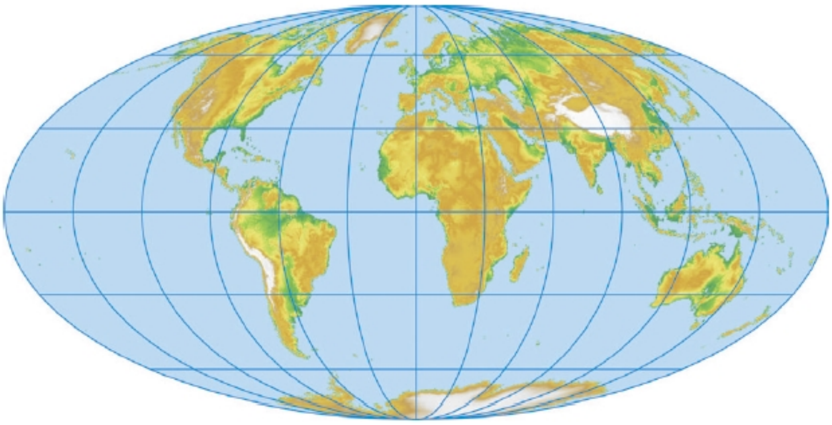

Figure 8.137: **Mollweide projection**

O'Connor and Robertson stated that Mollweide produced the map projection to correct the distortions in the Mercator projection, first used by Gerardus Mercator in 11569 (holocene calendar). While the Mercator projection is well adapted for sea charts, its very great exaggeration of land areas in high latitudes makes it unsuitable for most other purposes. In the Mercator projection the angles of intersection between the parallels and meridians, and the general configuration of the land, are preserved but as a consequence areas and distances are increasingly exaggerated as one moves away from the equator. To correct these defects, Mollweide drew his elliptical projection; but in preserving the correct relation between the areas he was compelled to sacrifice configuration and angular measurement. The Mollweide projection lay relatively dormant until J. Babinet reintroduced it in 11857 (holocene calendar) under the name "homalographic projection".

The well known equations of the Mollweide projections that we will prove further below read as follows:

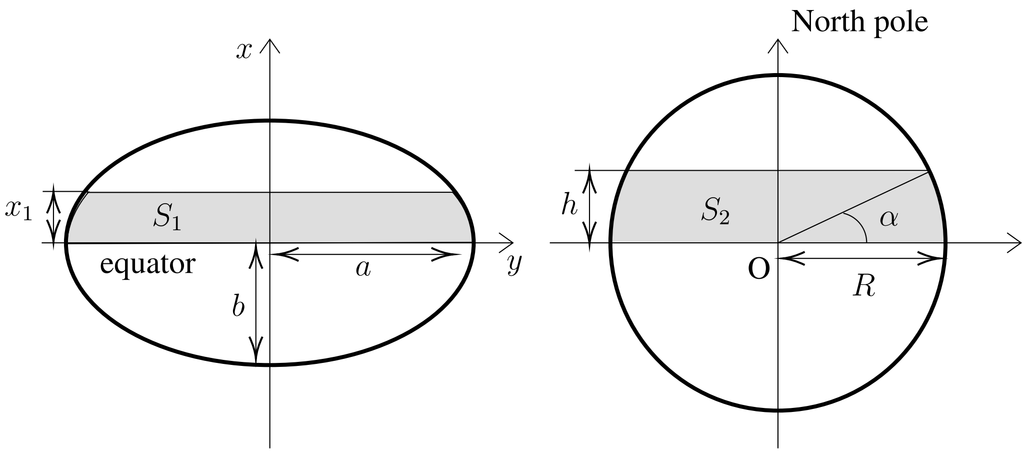
$$\boxed{x=\sqrt{2}R\sin(\beta)\qquad y=\frac{2\sqrt{2}}{\pi}R\lambda\cos(\beta)\qquad 2\beta+\sin(2\beta)=\pi\sin(\varphi)}\tag{8.4.135}$$

In these formulas x and y are rectangular coordinates in the plane of projection, φ (latitude angle) and λ (longitude angle) are geographic coordinates of the points on the sphere and R is the radius of the sphere to be mapped. The angle β is an auxiliary angle that is connected with the latitude φ by the relation $2\beta+\sin(2\beta)=\pi\sin(\varphi)$. For given latitude φ, the equation $2\beta+\sin(2\beta)=\pi\sin(\varphi)$ is a transcendental equation in β. In the past, it was solved by using tables and interpolation method. In our days, it is usually solved by using some iterative numerical method, like bisection or Newton-Raphson method.

Proof 8.19.2. Given the Earth's radius R, suppose the equatorial aspect of an equal-area projection with the following properties:

- A world map is bounded by an ellipse twice broader than tall
- Parallels map into parallel straight lines with uniform scale
- The central meridian is a part of straight line; all other ones are semi-elliptical arcs

Suppose an Earth-sized map; let us define two regions, S_1 on the map and S_2 on the Earth, both bounded by the equator and a parallel (the figure depicts a 2D representation but the left geometry is an ellipse - not an ellipsoid ! - and the right one a sphere):



The equal-area property can be used to calculate x for given φ. Given x and λ (longitude), y can be calculated immediately from the ellipse equation, since horizontal scale is constant. Equation of ellipse centred in origin, with major axis on y-axis is as we already know:

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1 \Rightarrow y^2=b^2\left(1-\frac{x^2}{a^2}\right) \qquad (8.4.136)$$

For $0 \leq x \leq a$:

$$y=\frac{b}{a}\sqrt{a^2-x^2} \qquad (8.4.137)$$

The area between y-axis and parallel mapped into $x=x_1$ is:

$$S_1=2\int_0^{x_1} y\mathrm{d}x=2\frac{b}{a}\int_0^{x_1}\sqrt{a^2-x^2}\mathrm{d}x \qquad (8.4.138)$$

Let us introduce the auxiliary angle:

$$x=a\sin(\beta) \qquad 0\leq x\leq a, 0\leq\beta\leq\frac{\pi}{2} \qquad (8.4.139)$$

and:

$$\mathrm{d}x=a\cos(\beta)\mathrm{d}\beta \qquad (8.4.140)$$

then:

$$\int\sqrt{a^2-x^2}\mathrm{d}x=\int\sqrt{a^2\left(1-\sin^2(\beta)\right)}a\cos(\beta)\mathrm{d}\beta=a^2\int\cos^2(\beta)\mathrm{d}\beta \qquad (8.4.141)$$

Since:

$$\cos^2(\alpha)=\frac{1+\cos(2\alpha)}{2} \qquad (8.4.142)$$

Then:

$$\begin{aligned}a^2\int\cos^2(\beta)\mathrm{d}\beta&=a^2\int\frac{1+\cos(2\beta)}{2}\mathrm{d}\beta=\frac{a^2}{2}\left(\int\mathrm{d}\beta+\int\cos(2\beta)\mathrm{d}\beta\right)\\&=\frac{a^2}{2}\left(\beta+\frac{\sin(2\beta)}{2}\right)+c^{te}\end{aligned}\tag{8.4.143}$$

Therefore:

$$S_1=2\frac{b}{a}\left(\frac{a^2}{2}\left(\beta+\frac{\sin(2\beta)}{2}\right)+c^{te}\right)_0^\beta=\frac{ab}{2}(2\beta+\sin(2\beta))=2R^2(2\beta+\sin(2\beta))\tag{8.4.144}$$

for some $0\leq\beta\leq\pi/2$, corresponding to $x_1=a\sin(\beta)$ and because of $ab\pi=4R^2\pi$.

Now let us calculate the "spherical zone":

$$\begin{aligned}S_2&=\int_{\theta=\mathrm{lat}_1}^{\mathrm{lat}_2}2\pi r'\mathrm{d}\theta=\int_{\theta=\mathrm{lat}_1}^{\mathrm{lat}_2}2\pi r\cos(\theta)\mathrm{d}\theta=2\pi r\int_{\theta=\mathrm{lat}_1}^{\mathrm{lat}_2}\cos(\theta)\mathrm{d}\theta\\&=2\pi r(-\sin(\theta))\Big|_{\theta=\mathrm{lat}_1}^{\mathrm{lat}_2}=2\pi r(\sin(\mathrm{lat}_1)-\sin(\mathrm{lat}_2))\end{aligned}\tag{8.4.145}$$

Therefore on a sphere, the area between the equator and parallel φ (i.e. $\mathrm{lat}_2=0$) is:

$$S_2=2\pi Rh=2\pi R^2\sin(\varphi)\tag{8.4.146}$$

But as $S_1=S_2$, then:

$$2R^2(2\beta+\sin(2\beta))=2\pi R^2\sin(\varphi)\tag{8.4.147}$$

Hence:

$$S_1=S_2\Leftrightarrow 2R^2(2\beta+\sin(2\beta))=2\pi R^2\sin(\varphi)\tag{8.4.148}$$

Simplifying we fall back the third relation of the Mollweide projection:

$$2\beta+\sin(2\beta)=\pi\sin(\varphi)\tag{8.4.149}$$

The auxiliary angle β, as already mentioned, must be found by interpolation or successive approximation.

Finally, since horizontal scale is uniform, from the two equalities (remember that the left $ab\pi$ is the surface of the elliptical projection 2D and the right $4R^2\pi$ is the surface of the projected sphere!):

$$ab\pi=4R^2\pi\qquad b=2a\tag{8.4.150}$$

We get:

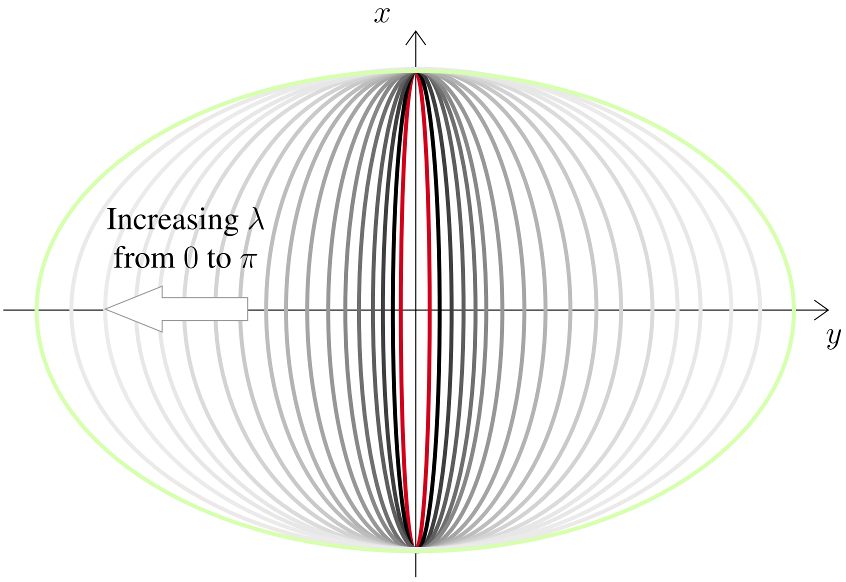
$$a=\sqrt{2}R\tag{8.4.151}$$

and therefore we can fall back on the first relation of the Mollweide projection:

$$x=a\sin(\beta)=\sqrt{2}R\sin(\beta)\tag{8.4.152}$$

Now, remember that λ is the longitude that goes starting from 0 [rad], to $-\pi$ on the West to $+\pi$ on the East. As it is symmetrical, from the meridian 0 [rad] just having one of the value of the angle going to West or East in enough information to make the mapping on the ellipse (as it is symmetrical!). The clever idea now is to shrink the elliptical projection so that when the latitude is near zero we get a very small projection ellipse as visible in red below and when it is equal to $+\pi$ we get the whole projection ellipse in green below (remember we do that in the horizontal direction of y). So multiplying the elliptic function y by the ratio λ/π will give the expected shrinkage:

$$y=\left(\frac{b}{a}\sqrt{a^2-x^2}\right)\frac{\lambda}{\pi} \tag{8.4.153}$$



Therefore:

$$y=\frac{2\lambda}{\pi}\sqrt{2R^2-x^2}=2\sqrt{2R^2-2R^2\sin^2(\beta)}\frac{\lambda}{\pi}=\frac{2\sqrt{2}\lambda}{\pi}R\sqrt{1-\sin^2(\beta)} \tag{8.4.154}$$

Then we fall back on the second relation of the Mollweide projection:

$$y=\frac{2\sqrt{2}}{\pi}R\lambda\cos(\beta) \tag{8.4.155}$$

We have all of the three relations and this finish the proofs!

■ Q.E.D.

Although the applied condition was that a half of the sphere has to be mapped onto a disc, the final projection equations hold for the whole sphere and give its image situated into an ellipse.

Let us consider the shape of the Mollweide projection of the whole sphere. From:

$$x=\sqrt{2}R\sin(\beta) \qquad y=\frac{2\sqrt{2}}{\pi}R\lambda\cos(\beta) \tag{8.4.156}$$

it is easy to get the equation of a meridian in the projection:

$$\left(\frac{x}{\sqrt{2}R}\right)^2+\left(\frac{\pi y}{2\sqrt{2}R\lambda}\right)^2=1 \tag{8.4.157}$$

It is obvious that for a given λ, the relation above is the equation of an ellipse. It follows that the semi-axis a is constant, while b depends on the longitude λ. If we take $\lambda=\pi$, than $b=2\sqrt{2}R$, and $a:b=1:2$ and that is the ratio of semi-axes in the Mollweide projection. The question arises: is it possible to find out a pseudocylindrical equal-area projection that will give the whole world in an arbitrary ellipse satisfying any given ratio $a:b$ or $b:a$? The answer is yes (!) and this leads to "Generalized Mollweide projection". But as the proof is of no interest in this textbook, the reader can refer to [335] for a detailed proof of it.

So the Mollweide is a pseudocylindrical projection in which the equator is represented as a straight horizontal line perpendicular to a central meridian one-half its length. The other parallels compress near the poles, while the other meridians are equally spaced at the equator. The meridians at 90 degrees East and West form a perfect circle, and the whole Earth is depicted in a proportional $2:1$ ellipse.

Notice that the Mollweide and Hammer projections are occasionally confused, since they are both equal-area and share the elliptical boundary; however, the latter design has curved parallels and is not pseudocylindrical:

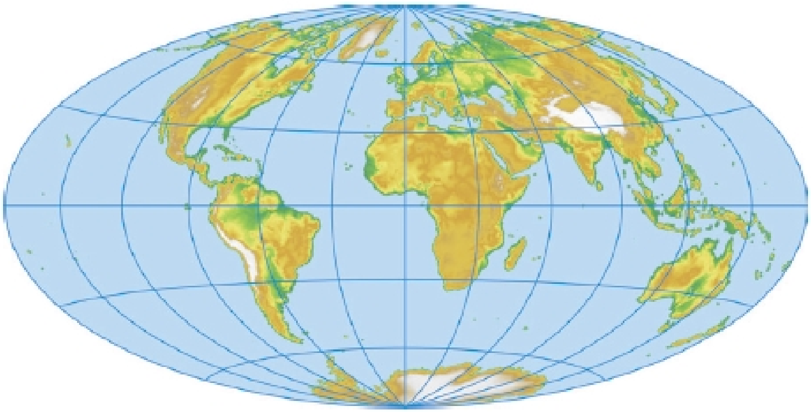


Figure 8.138: **Hammer projection**

8.4.4 Other perspectives and Laws of linear perspective

We can also choose any other angle of perspective and that not keep anything as equal but that are just well adapted to the technology or to human perception. For example the game Diablo II or Age of Empire use an angle in degrees of $53.130102°$ (rounded to 53) as for old $4:3$[8] screens it gives as result that an object have a vanishing line on the upper left corner of the $4:3$ screen will also pass trough the bottom right corner of the screen. It is therefore just choice of comfort!

---

[8] The origin of the $4:3$ is interesting and useful as the ratio forms a Pythagorean triangle, meaning that the length of the diagonal (hypotenuse) is an exact integer value (of pixels...).

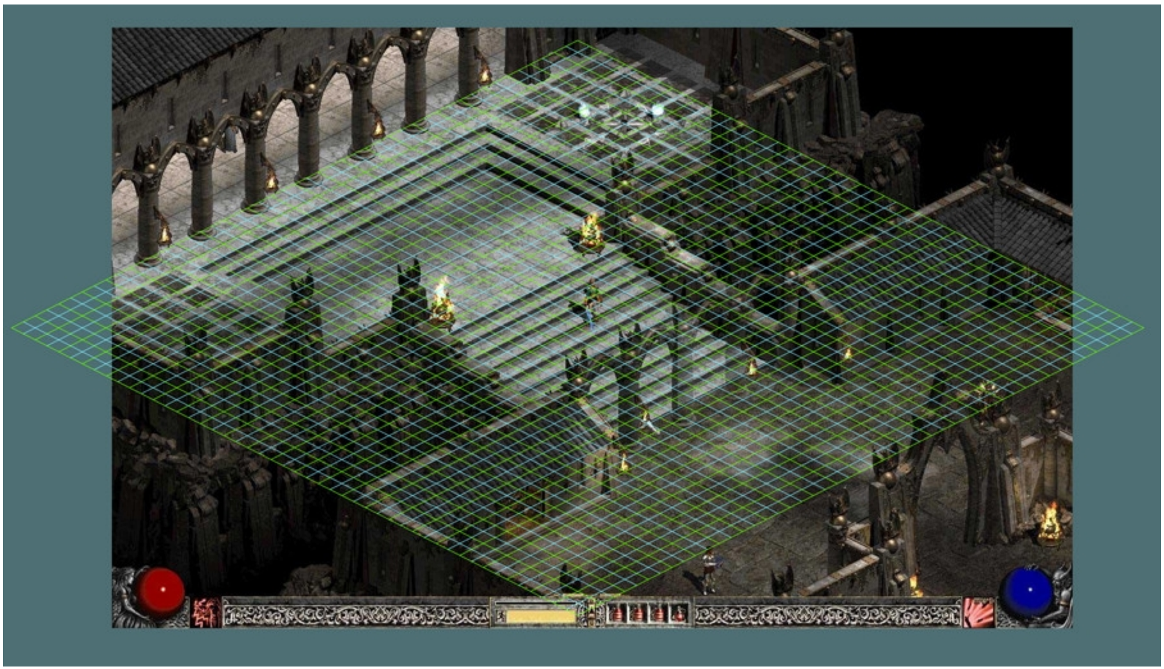

Figure 8.139: **Diablo II perspective grid**

Alternatively there are also a few games which use a trimetric projection where one axis is $1:2$ and the other is $2:1$ as below:

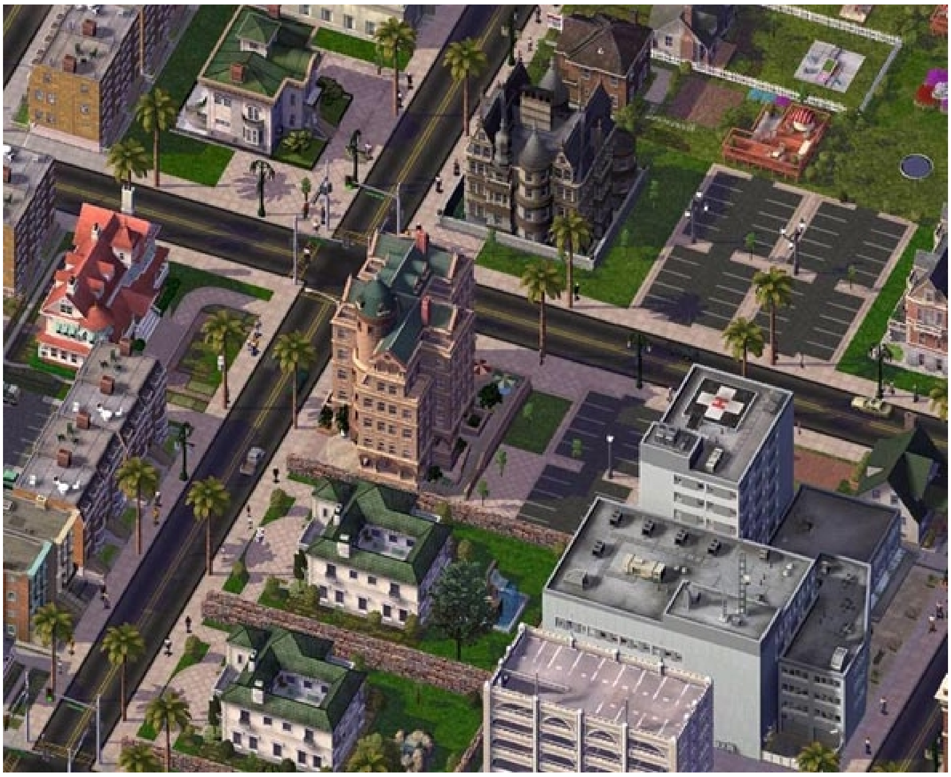

Figure 8.140: **Example of trimetric projection**

Figure 8.142: **Some common types of projections**

Now the reader has enough knowledge to fully understand the laws of linear perspective:

L1. **The law of horizon line:** This law states that there is only one horizon line (but there can be no horizon line like in the intergalactic outer space).

L2. **The law of eye height:** The horizon line, when it exists, is the line of the eye level of the observer (and obviously the eye height is independent of gaze direction!).

L3. **The law of vanishing points:** This law states that all straight lines that defines the contour of a shape or object, if extended, arrive on the horizon line at a vanishing point when we consider conical projection/perspective (and therefore all parallel straight lines defining the contour of a shape or object converge on the horizon line at the same vanishing points[9]).

Notice that vanishing points don't have to be aligned on the horizon line even if it is most common case!

When the vanishing point is placed at the zenith (above the horizon), we look up to see the object. We speak then of "worm's eye view", since we are in the position of a worm looking towards the zenith. All vanishing lines above the horizon line are descending lines.

When the vanishing point is placed at the nadir (below the horizon), we look down. This is named the "bird's eye view". All vanishing lines below the horizon line are ascending lines.

Remark

In two-point perspective, we draw vertical lines, vertical! In three-point perspective, our vertical lines are at an angle, converging on the third vanishing point above or below. Two-point perspective is generally sufficient for most basic scenes, while three-point perspective corresponds to reality (because two-point perspective does not account for vertical distortion).

L4. **The law of diminution:** This law states that as objects get farther away from us they appear to get small and can even seems to vanish if their size is smaller than the resolving power of the human eye.

In perfect conditions, the human eye has a resolving power of 60 arc seconds (i.e. angular resolution of 0.008 degrees). In an older person, however, the ability to resolve certain objects is somewhat reduced. This is mainly due to the reduced size of the pupil, but also to the constraints of anatomical and physiological vision.

L5. **The law of Overlap:** This law states that when one object is in front of another, it will cover it and describe their spatial relationships. If the projection plane is curved (positive curvature like a sphere for example) the landscape may be in front of objects that are further than the horizon.

L6. **The law of Convergence:** This law states that as parallel lines go away from us, they appear to converge, or meet, at a point when we consider conical projection/perspective. We can also say this in reverse: When parallel lines come toward us, they diverge, or get farther apart.

L7. **The law of Atmospheric perspective:** This law describes the properties that affect an objects appearance as it moves away in an environment having an isotropic and homogeneous atmosphere and standard pressure and temperature:

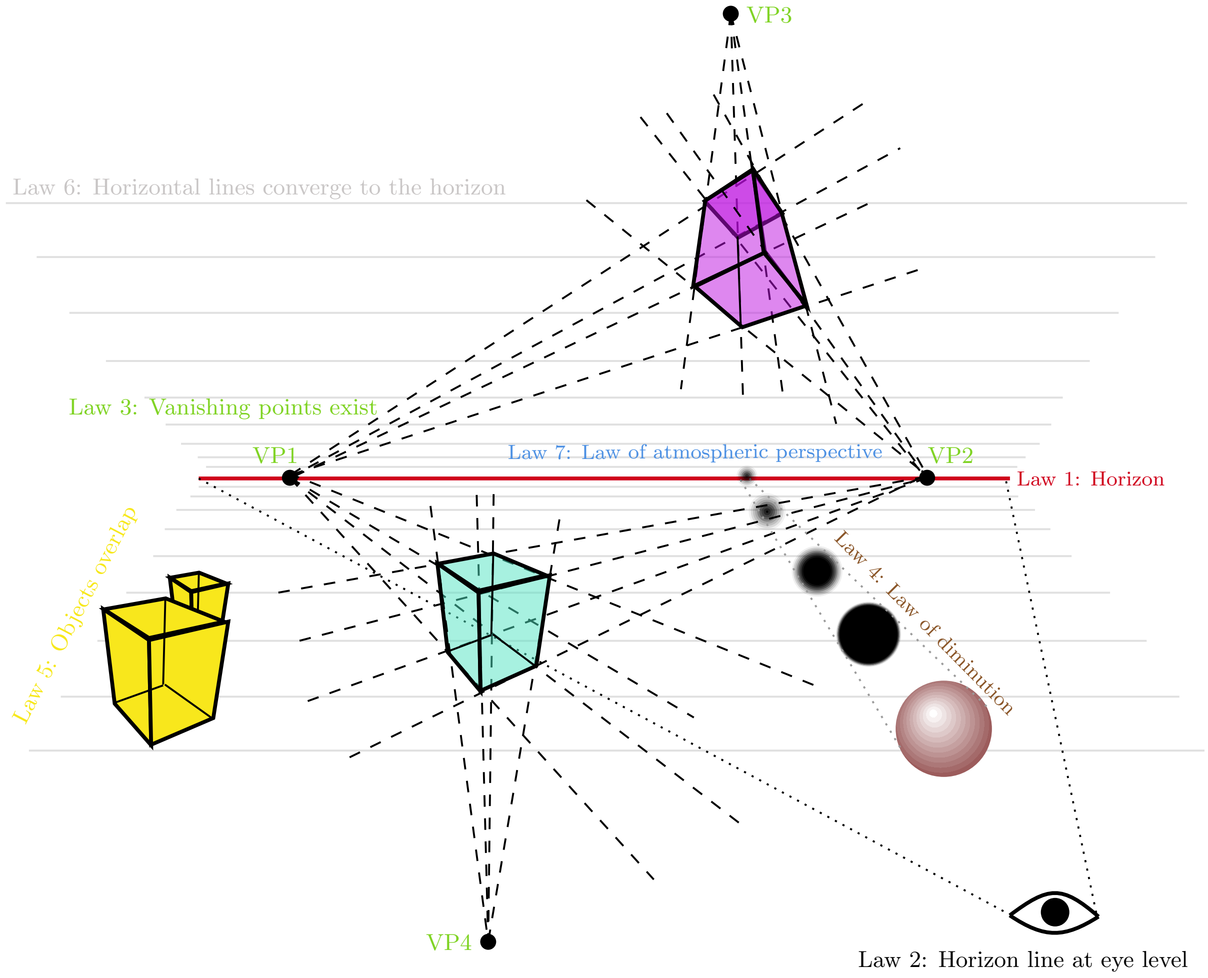
- Light and dark variation of a same color get closer creating less contrast (the light is diffused in an atmosphere)
- Colors get less saturated (for the same reasons as the previous point)
- Colors get cooler, shifting towards blues and purples in a typical Earth like atmosphere during a sunny day.

---

[9] All vanishing straight lines below the horizon line are said to be "ascending lines" and all vanishing straight lines below the horizon line are said to be "descending lines".

- Edges gets softer (again because of the resolving power of the human eye or any other intermediate apparatus)
- We see less detail until the object cannot be distinguished from its background (resolving power again) or disappear below the horizon when the projective plan is a geometry with positive curvature.

Below we have an illustrated summary of these seven laws:



VP3
Law 6: Horizontal lines converge to the horizon
Law 3: Vanishing points exist
VP1
Law 7: Law of atmospheric perspective
VP2
Law 1: Horizon
Law 5: Objects overlap
Law 4: Law of diminution
VP4
Law 2: Horizon line at eye level

Figure 8.143: Summary of the seven laws of linear perspective

Two parallels lines with the laws of perspective seem to converge when in fact they don't:

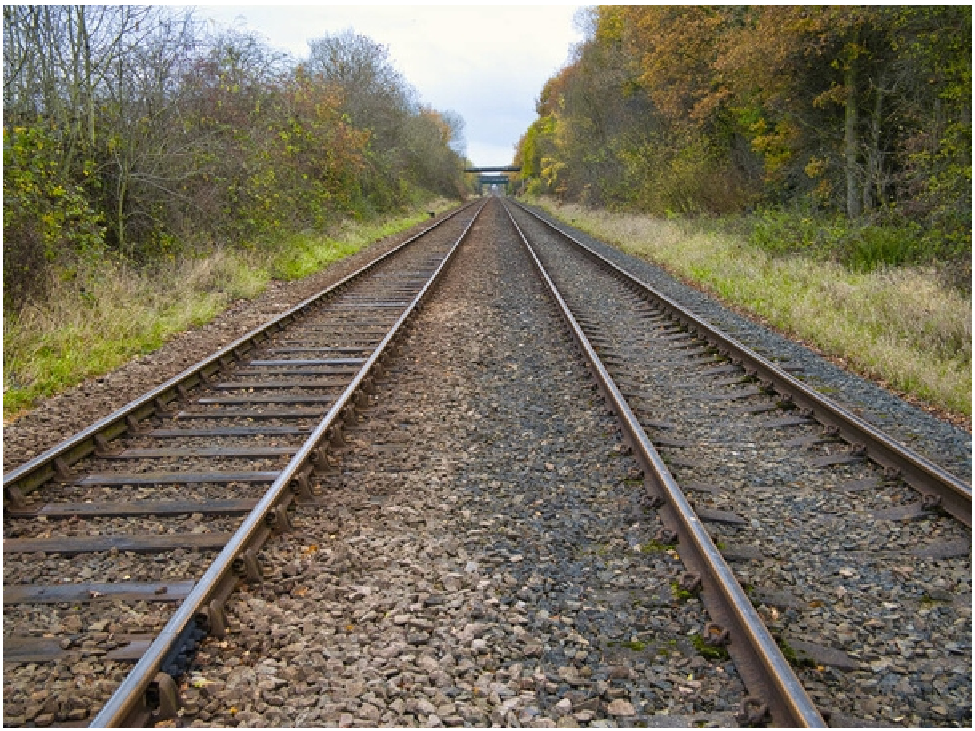


Figure 8.144: **Railway convergence perspective effect**

The same effect of perspective occurs with crepuscular rays that seem to converge locally when in fact they are almost parallel:

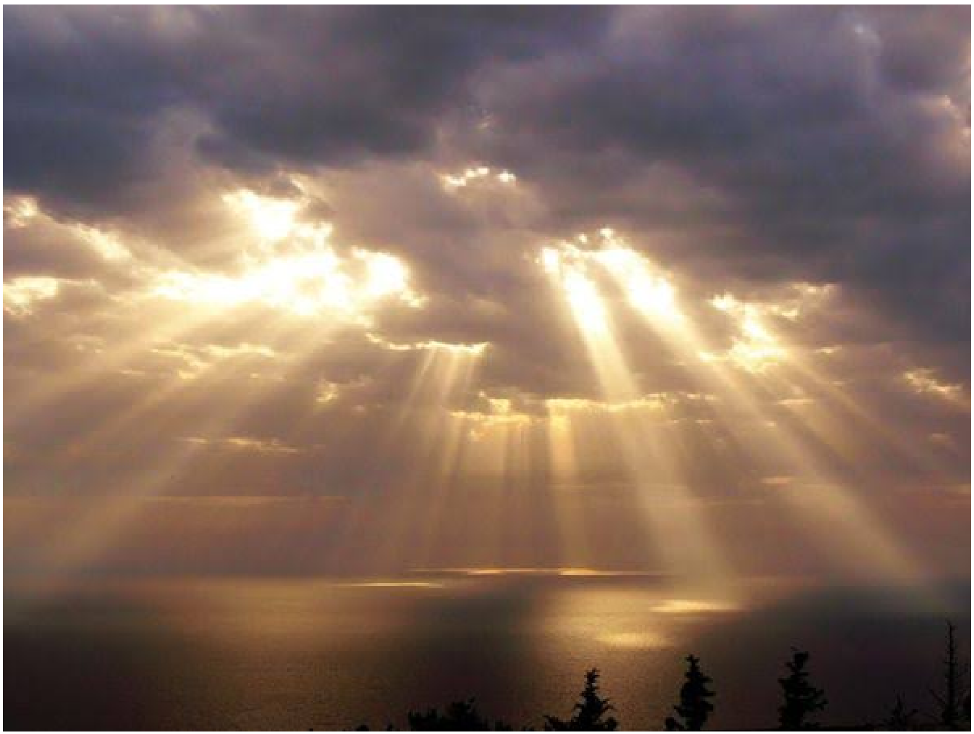

Figure 8.145: **Crepuscular rays**

And the same goes for shadows that seems to diverge (when in fact they converge towards the source) to the left for objects that are on the left and diverge to the right for objects that are on the right:

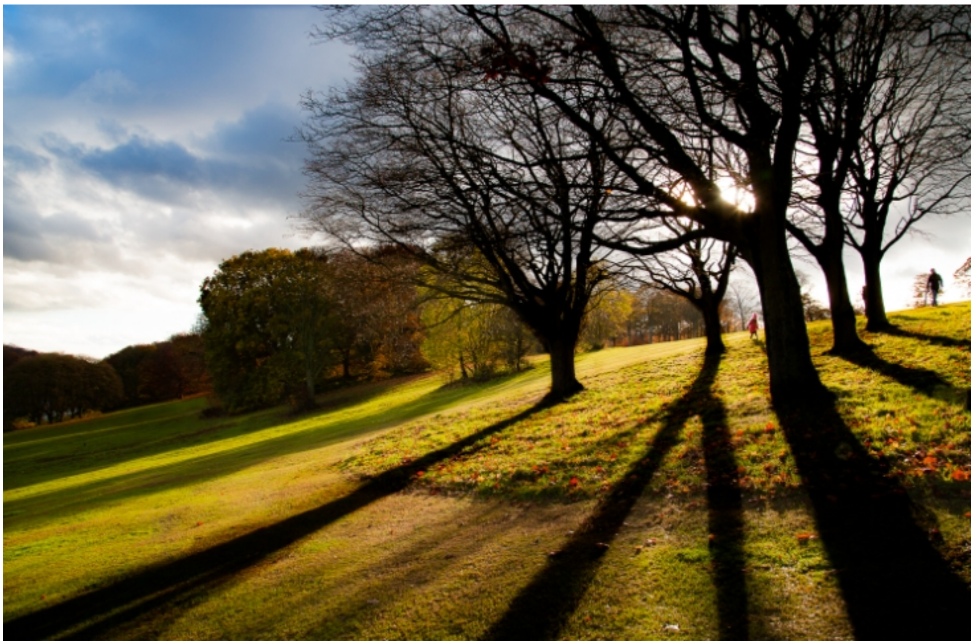

Figure 8.146: Shadows that seem to diverge

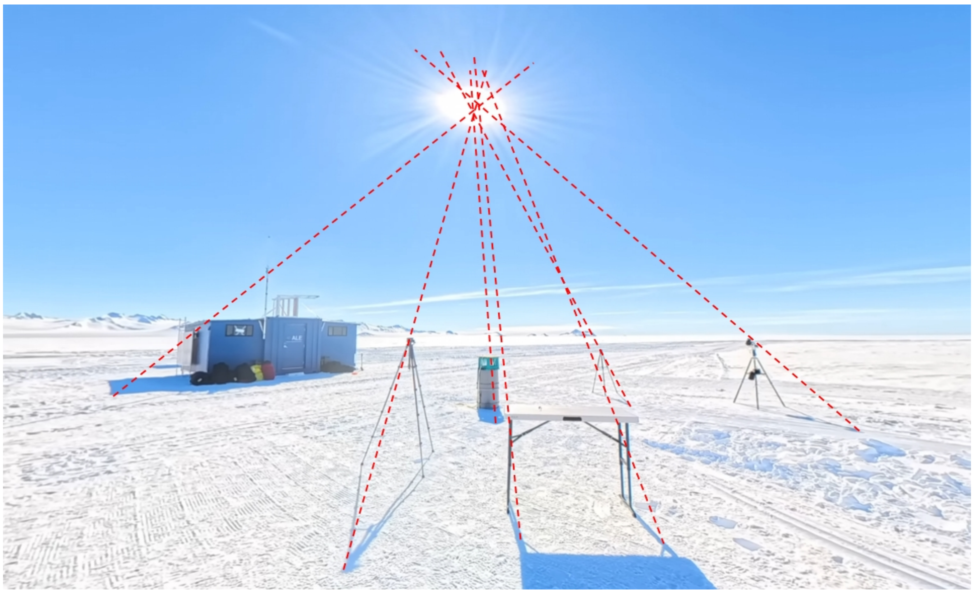
or the shadows in Antarctica during the Midnight Sun (here with a wide-angle camera that distorts the objects a little) if we trace the vanishing lines of the shadows we see that although they give the impression of converging towards a local Sun in accordance with the laws of linear perspective (while we will prove in the section of Astronomy that the Sun is about 150 million kilometers away) and that the shadows seem to diverge on the ground:



Definition (#8.4.355): The "midnight Sun" is the period when the entire Sun disc (determined thanks to a solar filter) remains continuously visible for 24 hours or more above the horizon, occurring in summer at latitudes north of the Arctic Circle (66°33′ N) and south of the Antarctic Circle (66°33′ S), due to the tilt of Earth's axis (sadly some scientists use a slightly different non-academic definition hence a variation of a few days in period value).

8.4.5 Homogeneous Coordinates (projection coordinates)

In mathematics, "homogeneous coordinates" also named "projection coordinates", introduced by August Ferdinand Möbius in the 119th century (holocene calendar), make calculations possible in the projective space as do the Cartesian coordinates in Euclidean space. Homogeneous coordinates are used extensively in computer graphics and more particularly for the representation of three dimensional (3D) scenes because they are adapted to projective geometry and allow to characterize the transformations of space under optimal algorithmic form. The matrix notation form is particularly used in 3D graphics programming libraries such as OpenGL and Direct3D.

We proved in our study of transformations in the plane and space (see section Euclidean Geometry page 2640) that the translation, the scaling, rotation or reflection were not possible to be translate represented in (real) matrix form without a trick that was to add a dummy extra dimension to the vector of coordinates and to the associated matrix transformation but we did it only for the translation. So let us see it now for all other classical transformation.

8.4.5.1 $\mathcal{P}^2$ Projective Space

Thus, we saw that the translation in $\mathbb{R}^2$ could be written in matrix form:

$$\begin{pmatrix} x' \\ y' \\ 1 \end{pmatrix} = T \cdot \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \begin{bmatrix} 1 & 0 & T_x \\ 0 & 1 & T_y \\ 0 & 0 & 1 \end{bmatrix} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \begin{pmatrix} x+T_x \\ y+T_y \\ 1 \end{pmatrix} \tag{8.4.158}$$

Therefore, always in $\mathbb{R}^2$, a scaling of factor k who was written:

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{bmatrix} k & 0 \\ 0 & k \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} k \cdot x \\ k \cdot y \end{pmatrix} \tag{8.4.159}$$

becomes in homogeneous coordinates:

$$\begin{pmatrix} x' \\ y' \\ 1 \end{pmatrix} = S \cdot \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \begin{bmatrix} S_x & 0 & 0 \\ 0 & S_y & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} \begin{pmatrix} S_x \cdot x \\ S_y \cdot y \\ 1 \end{pmatrix} \tag{8.4.160}$$

Hence, always in $\mathbb{R}^2$, a rotation of angle θ in the $x-y$ plane:

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{bmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{bmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x\cos(\theta) - y\sin(\theta) \\ x\sin(\theta) + y\cos(\theta) \\ 1 \end{pmatrix} \tag{8.4.161}$$

becomes (and as we proved it, this is indeed a rotation around the z-axis):

$$\begin{pmatrix} x' \\ y' \\ 1 \end{pmatrix} = R \cdot \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \begin{pmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \begin{pmatrix} x\cos(\theta) - y\sin(\theta) \\ x\sin(\theta) + y\cos(\theta) \\ 1 \end{pmatrix} \tag{8.4.162}$$

So always in $\mathbb{R}^2$, the reflection that was written along the x-axis by:

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \begin{pmatrix} -x \\ y \end{pmatrix} \tag{8.4.163}$$

becomes:

$$\begin{pmatrix} x' \\ y' \\ 1 \end{pmatrix} = \Delta \cdot \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \begin{pmatrix} -1 & 0 & \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} \begin{pmatrix} -x \\ y \\ 1 \end{pmatrix} \qquad (8.4.164)$$

and so on for other transformations that we have proved and that were resumed in the following figure we have already see and where the homogeneous coordinates are in gray:

Figure 8.147: **Summary of homogeneous coordinates transformations**

Mathematicians say then that we when we use the above transformations or the composition of some of them, we put ourselves in the projective space $\mathcal{P}^2$.

8.4.5.2 $\mathcal{P}^3$ Projective Space

Verbatim, we can do the same with a point P of $\mathbb{R}^3$ which will then in $\mathcal{P}^3$ be represented by a 4×1 coordinate vector:

$$\begin{pmatrix} x\\ y\\ z\\ w \end{pmatrix} \tag{8.4.165}$$

Thus we have in space the following transformation matrices:

- For translations:

$$T=\begin{bmatrix} 1 & 0 & 0 & T_x\\ 0 & 1 & 0 & T_y\\ 0 & 0 & 1 & T_z\\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{8.4.166}$$

- For rotations it is enough for sure in 3D to have as we proved it:

$$R_{ZYX}=R_ZR_YR_X=\begin{bmatrix} \cos(\phi) & \sin(\phi) & 0\\ -\sin(\phi) & \cos(\phi) & 0\\ 0 & 0 & 1 \end{bmatrix}\begin{bmatrix} \cos(\gamma) & 0 & -\sin(\gamma)\\ 0 & 1 & 0\\ \sin(\gamma) & 0 & \cos(\gamma) \end{bmatrix}\begin{bmatrix} 1 & 0 & 0\\ 0 & \cos(\theta) & \sin(\theta)\\ 0 & -\sin(\theta) & \cos(\theta) \end{bmatrix} \tag{8.4.167}$$

  But if we want to work with projection coordinates, this becomes obviously:

$$R_{ZYX}=\begin{bmatrix} \cos(\phi) & \sin(\phi) & 0 & 0\\ -\sin(\phi) & \cos(\phi) & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{bmatrix}\begin{bmatrix} \cos(\gamma) & 0 & -\sin(\gamma) & 0\\ 0 & 1 & 0 & 0\\ \sin(\gamma) & 0 & \cos(\gamma) & 0\\ 0 & 0 & 0 & 1 \end{bmatrix}\begin{bmatrix} 1 & 0 & 0 & 0\\ 0 & \cos(\theta) & \sin(\theta) & 0\\ 0 & -\sin(\theta) & \cos(\theta) & 0\\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{8.4.168}$$

- For homoteties (scaling) obviously:

$$S=\begin{bmatrix} S_x & 0 & 0 & 0\\ 0 & S_y & 0 & 0\\ 0 & 0 & S_z & 0\\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{8.4.169}$$

- In space, one can push in two coordinate axis directions and keep the third one fixed. The following is the shear transformation in both $x-$ and $y-$directions with shearing factors a and b, respectively, keeping the $z-$ coordinate the same (so its only one of the possible special cases):

$$\begin{pmatrix} x'\\ y'\\ z'\\ 1 \end{pmatrix}=\begin{bmatrix} 1 & 0 & a & 0\\ 0 & 1 & b & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{bmatrix}\begin{pmatrix} x\\ y\\ z\\ 1 \end{pmatrix}=\begin{pmatrix} x+az\\ y+bz\\ z\\ 1 \end{pmatrix} \tag{8.4.170}$$

  Thus, a point (x,y,z) in space is transformed to $(x+az,y+bz,z)$. Therefore, the z-coordinate does not change, while (x,y) is "pushed” in the direction of $(a,b,0)$ with a factor z.

Mathematicians say then that we when we use the above transformations or the composition of some of them, we put ourselves in the projective space $\mathcal{P}^3$.

We have proved above that in the case of the conical project, we had the following homographic transformations:

$$\begin{aligned} x' &= \frac{x\Delta}{z+\Delta} \\ y' &= \frac{y\Delta}{z+\Delta} \\ z' &= \Delta \end{aligned} \tag{8.4.171}$$

where x', y', z' are the projection of the relation points x, y, z on the table with a focal distance Δ for recall...

What is traditionally written by putting $z := z+\Delta$ and $f := \Delta$:

$$\begin{aligned} x' &= \frac{x\cdot f}{z} \\ y' &= \frac{y\cdot f}{z} \\ z' &= f \end{aligned} \tag{8.4.172}$$

where we see that if the focal distance f is infinite, the subject coincides with the XY plane (or if the object is infinitely far away as it is equivalent...).

Let us put:

$$\frac{z}{f} = s \tag{8.4.173}$$

We can the write:

$$\begin{aligned} sx' &= x \\ sy' &= y \\ z' &= f \\ s &= \frac{z}{f} \end{aligned} \tag{8.4.174}$$

Or better:

$$\begin{aligned} sx' &= x \\ sy' &= y \\ sz' &= z \\ s &= \frac{z}{f} \end{aligned} \tag{8.4.175}$$

We then use the following matrix for the conical projection:

$$\boxed{P_C = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1/f & 0 \end{bmatrix}} \tag{8.4.176}$$

and then we normalize the coordinates by the ratio z/f. Indeed (a reader requested the details):

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \frac{1}{\frac{z}{f}} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1/f & 0 \end{bmatrix} \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \frac{f}{z} \begin{pmatrix} x \\ y \\ z \\ z/f \end{pmatrix} = \begin{pmatrix} \frac{xf}{z} \\ \frac{yf}{z} \\ z \\ 1 \end{pmatrix} \tag{8.4.177}$$

8.5. Analytical Geometry

THE "analytic geometry" is the branch of geometry that deals with the study of geometric shapes and their properties using the advanced tools of Calculus such as functional analysis, vector calculus and linear algebra. Its border lies in the tools used and originated by the work of René Descartes in the early 117th century (holocene calendar). The "vector geometry" is a subset of analytical geometry and we will also us it in this section as in this of Differential Geometry.

Remark

When we use for these same subjects that will follow the differential and integral calculus we then say that we do "differential geometry" (see section of the same name page 2850).

Analytic geometry is a very broad area (like everything else in this textbook) then... we discussed here that the elements indispensable for the study of physics (especially astronomy and quantum physics particle) and engineering (spacial engineering). These elements are also often studied in small classes and are (cited in order of study at high-school): the conics, the equations of the line, of the plan, of the sphere, etc. their intersections, their tangent planes and many others.

The reader will notice that we begin this section with conics and not straight lines and this is simply because we will use much more conics properties than straight lines in this textbook. For analytical geometric properties of straight lines see the subsection after the conics.

8.5.1 Conics

It has been very difficult for us to choose whether to put the study of the conics in the chapter on Algebra or on Geometry. We finally decided to put this study in this chapter (hence Geometry...) which suggests that the reader that has made a linear reading of this textbook has already covered all chapters and sections presenting the mathematical tools necessary to study of conics. We hope that our choice will be the best one for the reader.

The study of conic will be very useful in the section of Astronomy (we own to Kepler is many results from on the study on conics) and also in the sections of Geometrical Optics, Statistics and Industrial Engineering. It is therefore appropriate to go in the details of this subject.

8.5.1.1 Algebraic approach

Consider $(\text{O},\vec{i},\vec{j})$ an orthonormal plan. The simplest algebraic curves that we can find after the lines whose general form equations are (reminder):

$$ax+by+c=0 \tag{8.5.1}$$

are the curves of the second degree, named "analytical conics", that is to say by extension:

$$\boxed{\underbrace{\alpha x^2+\beta y^2+\gamma xy}_{\text{quadratic term}}+\delta x+\varepsilon y+\zeta=0} \tag{8.5.2}$$

with α,β,γ all non-zero.

The second degree corresponding curves are named "conics" (also named "quadrics" because of the presence of a quadratic term). The conic will be named "proper conic" if it is an ellipse, a parabola or a hyperbole as we shall see further below.

This last relation can also be written in matrix form (very important in the practice of Numerical Methods as we will see it in the section of the same name and in the classification of differential equations as discussed in the section of Differential and Integral Calculus):

$$[x \quad y]=\begin{bmatrix}\alpha & \dfrac{\beta}{2}\\ \dfrac{\beta}{2} & \gamma\end{bmatrix}\begin{bmatrix}x\\ y\end{bmatrix}+[\delta \quad \varepsilon]\begin{bmatrix}x\\ y\end{bmatrix}+\zeta=\vec{x}^TA\vec{x}+B^T\vec{x}+C \tag{8.5.3}$$

notation for which there exists several variants...

For example, the function:

$$f(x,y)=x^2+y^2+2bxy-5x-4y+g \tag{8.5.4}$$

gives for different values of g the following paths:

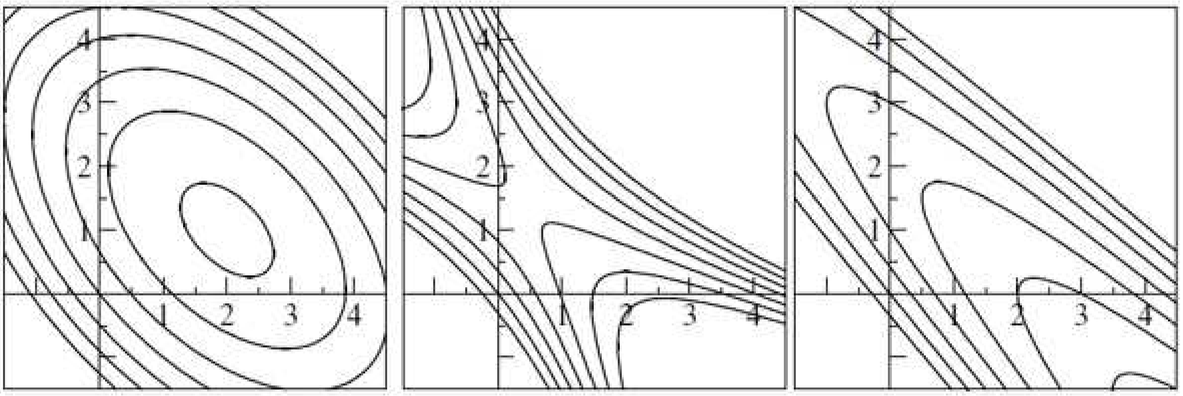

Figure 8.148: **Conics with respectively $b=0.5,1.5$ and 1 and more values of g**

Our first task will be to obtain, by translation and rotation of the coordinate system in which this relation is expressed, a reduced equation much simpler by eliminating the xy term. Indeed, let us choose a new referential being deduced by the previous one just by a rotation of angle θ. Let x' and y' be the coordinates of the new points. We have (see section Euclidean Geometric page 2648):

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{bmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{bmatrix} \tag{8.5.5}$$

Thus:

$$\begin{aligned} x &= \cos(\theta)x' - \sin(\theta)y' \\ y &= \sin(\theta)x' + \cos(\theta)y' \end{aligned} \tag{8.5.6}$$

The equation becomes:

$$\alpha(\cos(\theta)x' - \sin(\theta)y')^2 + \beta(\sin(\theta)x' + \cos(\theta)y')^2 \tag{8.5.7}$$

$$+\gamma(\cos(\theta)x' - \sin(\theta)y')(\sin(\theta)x' + \cos(\theta)y') + \ldots = 0 \tag{8.5.8}$$

So we want all the terms $x'y'$ to be grouped as:

$$-2\alpha\cos(\theta)\sin(\theta) + 2\beta\cos(\theta)\sin(\theta) + \gamma(\cos^2(\theta) - \sin^2(\theta)) \tag{8.5.9}$$

Since (see section Trigonometry page 2519):

$$\cos^2(\theta) - \sin^2(\theta) = \cos(2\theta) \quad \text{and} \quad \sin(\alpha+\beta) = \sin(\beta)\cos(\alpha) + \cos(\beta)\sin(\alpha) \tag{8.5.10}$$

substituting, we get:

$$(\beta - \alpha)\sin(2\theta) + \gamma\cos(2\theta) = 0 \tag{8.5.11}$$

To have only the terms in $x'y'$ that simplifies, we just have to choose the rotation angle θ such as:

$$\frac{\sin(2\theta)}{\cos(2\theta)} = \frac{\gamma}{\alpha - \beta} = \tan(2\theta) \tag{8.5.12}$$

Therefore we will consider now the equation:

$$\boxed{\alpha x^2 + \beta y^2 + \delta x + \varepsilon y + \zeta = 0} \tag{8.5.13}$$

1. If we write that $\alpha = 0$ and $\beta = 0$. And we divide by β, we can take us back to an equation of the following type:

   $$y^2 + \gamma x + \delta y + \varepsilon = 0 \tag{8.5.14}$$

   Where:

   - If $\gamma \neq 0$, we end up with an equation describing the figure of a "parabola" of axis parallel to OX.
   - If $\gamma = 0$, it is a degenerate case (a degenerate conic is a conic that is reduced to be two lines that may or may not be parallel or a single line).

2. If we write $\alpha \neq 0$ and $\beta = 0$ thus the situation is treated exactly as before.

3. If $\alpha \neq 0$ and $\beta \neq 0$, we can remove the terms δx and εy terms as follows:

$$\alpha\left(x+\frac{\delta}{2\alpha}\right)^2+\beta\left(y+\frac{\varepsilon}{2\beta}\right)+\gamma=0 \tag{8.5.15}$$

And by a simple change of referential via translations, we arrive at an equation that looks like following:

$$\alpha X^2+\beta Y^2+\gamma=0 \tag{8.5.16}$$

- If $\gamma=0$ the previous relations simplifies to:

$$\alpha X^2=-\beta Y^2 \tag{8.5.17}$$

And therefore it is obvious that if $\text{sgn}(x)=\text{sgn}(y)$ there is only the trivial solution $X=Y=0$ if we stay in $\mathbb{R}$. Instead if $\text{sgn}(x)\neq\text{sgn}(y)$ thus we have an infinity of solutions represented by a straight line.

- If $\gamma \neq 0$ let us put that:

$$\alpha=\text{sgn}(\alpha)\frac{1}{\alpha'^2} \quad \text{and} \quad \beta=\text{sgn}(\beta)\frac{1}{\beta'^2} \tag{8.5.18}$$

and let us divide by $|\gamma|$ such that:

$$\text{sgn}(\alpha)\frac{X^2}{|\gamma|\alpha'^2}+\text{sgn}(\beta)\frac{Y^2}{|\gamma|\beta'^2}+\text{sgn}(\gamma)=0 \tag{8.5.19}$$

If we put now:

$$\frac{X^2}{|\gamma|\alpha'^2}=\frac{1}{a^2} \quad \text{and} \quad \frac{Y^2}{|\gamma|\beta'^2}=\frac{1}{b^2} \tag{8.5.20}$$

We get:

$$\text{sgn}(\alpha)\frac{X^2}{a^2}+\text{sgn}(\beta)\frac{Y^2}{b^2}=-\text{sgn}(\gamma) \tag{8.5.21}$$

So we therefore have several possible situations:

$$\boxed{\begin{array}{ll} +\dfrac{X^2}{a^2}+\dfrac{Y^2}{b^2}=+1 & -\dfrac{X^2}{a^2}-\dfrac{Y^2}{b^2}=-1 \\ +\dfrac{X^2}{a^2}-\dfrac{Y^2}{b^2}=+1 & -\dfrac{X^2}{a^2}+\dfrac{Y^2}{b^2}=-1 \\ -\dfrac{X^2}{a^2}+\dfrac{Y^2}{b^2}=+1 & +\dfrac{X^2}{a^2}-\dfrac{Y^2}{b^2}=-1 \\ \xcancel{-\dfrac{X^2}{a^2}-\dfrac{Y^2}{b^2}=+1} & \xcancel{+\dfrac{X^2}{a^2}+\dfrac{Y^2}{b^2}=-1} \end{array}} \tag{8.5.22}$$

Two terms above are impossible in $\mathbb{R}^2$, this is why we crossed them (the sum of two positive numbers can not be negative and vice versa).
There are several cases of interesting figures:

(a) For:

$$+\frac{X^2}{a^2}+\frac{Y^2}{b^2}=+1 \qquad -\frac{X^2}{a^2}-\frac{Y^2}{b^2}=-1 \tag{8.5.23}$$

and $a=b=1$, we have a unit circle. The reader can have fun testing this with the following commands in Maple™ 4.00b:

```
>with(plots):
>a:=1;b:=1;
>implicitplot(x^2/a^2+y^2/b^2=1,x=-10..10,y=-10..10);
```

(b) For:

$$+\frac{X^2}{a^2}+\frac{Y^2}{b^2}=+1 \qquad -\frac{X^2}{a^2}-\frac{Y^2}{b^2}=-1 \tag{8.5.24}$$

and $\forall a,b\in\mathbb{R}^*$ we have an ellipse (which therefore contains the specific case of the circle) with half-axes a and b (for the visual representation of an ellipse see further below or otherwise see the section of Geometric Forms).

The reader can have fun testing this with the following command in Maple™ 4.00b:

```
>with(plots):
>a:=4;b:=8;
>implicitplot(x^2/a^2+y^2/b^2=1,x=-10..10,y=-10..10);
```

(c) For:

$$\begin{array}{cc} \dfrac{X^2}{a^2}+\dfrac{Y^2}{b^2}=+1 & -\dfrac{X^2}{a^2}+\dfrac{Y^2}{b^2}=-1 \\ -\dfrac{X^2}{a^2}+\dfrac{Y^2}{b^2}=+1 & \dfrac{X^2}{a^2}-\dfrac{Y^2}{b^2}=-1 \end{array} \tag{8.5.25}$$

and $\forall a,b\in\mathbb{R}^*$, we get hyperbolas whose symmetry axis is parallel to OX or OY (for visual representation see further below). We say that the hyperbole is an "equilateral hyperbola" when $a=b$.

The reader can have fun testing this with the following commands in Maple™ 4.00b:

```
>with(plots):
>a:=4;b:=4;
>implicitplot(x^2/a^2-y^2/b^2=1,x=-10..10,y=-10..10);
```

The term "conical" comes from the fact that one of the first definitions of conicals consisted of the intersection of a cone and a plane.

Indeed, given:

$$z^2=x^2+y^2 \tag{8.5.26}$$

the equation of a cone having an angle at the top of $\pi/4$ (or an angle of $\pi/2$ relatively to its surface and the x-axis). This is simple the application of Pythagorean theorem...

Plus also given an oriented plane with an angle θ relatively to the Z axis:

$$x=f(y,z)=\cos(\theta)y+\sin(\theta)z:=h \tag{8.5.27}$$

where the reader can see that if $\theta=0$ we get $z=h$ for $\forall x,y$ the plane is therefore parallel to $x\text{O}y$, if $\theta=\pi/2$ we get $y=h$ for $\forall z,y$ the plane is parallel to $x\text{O}z$. In both situation and for every θ the plane never intersect with the axis X and we have a normal vector that is always in the plane $x\text{O}y$.

This normal vector has almost obviously the following coordinates (we use the cosine-director notation):

$$\vec{n}=(0,\cos(\theta),\sin(\theta))=\left(0,\cos(\theta),\cos\left(\frac{\pi}{2}-\theta\right)\right) \tag{8.5.28}$$

Consider now the rotation matrix in the space $\mathbb{R}^3$ relative to the axis Oz (see section Euclidean Geometry page 2648):

$$\begin{pmatrix}x'\\y'\\z'\end{pmatrix}=\begin{bmatrix}1&0&0\\0&\cos(\theta)&-\sin(\theta)\\0&\sin(\theta)&\cos(\theta)\end{bmatrix}\begin{pmatrix}x\\y\\z\end{pmatrix}=\begin{pmatrix}x\\y\cos(\theta)-z\sin(\theta)\\y\sin(\theta)+z\cos(\theta)\end{pmatrix} \tag{8.5.29}$$

So we have for expression of rotation of our plane:

$$\cos(\theta)y+\sin(\theta)z=\cos(\theta)(\cos(\theta)-z\sin(\theta))+\sin(\theta)(\cos(\theta)-z\sin(\theta)):=h \tag{8.5.30}$$

After simplification, $\forall\theta$:

$$y=h \tag{8.5.31}$$

This just mean that when we apply the rotation matrix to our plane with the same angle θ we take it to is "initial" position.

Identically, for the cone, a rotation according to the Z axis :

$$(y\sin(\theta)+z\cos(\theta))^2=x^2+(y\cos(\theta)-z\sin(\theta))^2 \tag{8.5.32}$$

After development and simplification:

$$x^2-(y^2-z^2)\cos(2\theta)+yz2\sin(2\theta)=0 \tag{8.5.33}$$

Equation that gives a horizontal cone for $\theta=0$ and a vertical one for $\theta=\frac{\pi}{2}$.

Thus, we have one possible general system:

$$\left\{\begin{array}{l}y=h\\x^2-(y^2-z^2)\cos(2\theta)+yz2\sin(2\theta)=0\end{array}\right. \tag{8.5.34}$$

We see then that for:

- $\theta\in\left]\dfrac{\pi}{4},\dfrac{\pi}{2}\right]$ we get an intersection between the plane and the cone giving an ellipse
- $\theta=\dfrac{\pi}{4}$ we get a parabola
- $\theta\in\left[0,\dfrac{\pi}{4}\right[$ we get a hyperbola

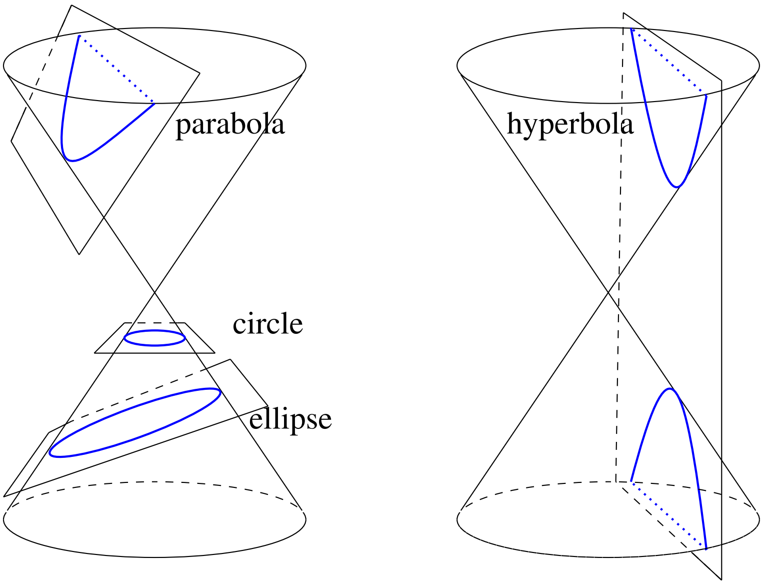

Figure 8.149: **Various intersections between a cone and a plane (author: Ridlo W. Wibowo)**

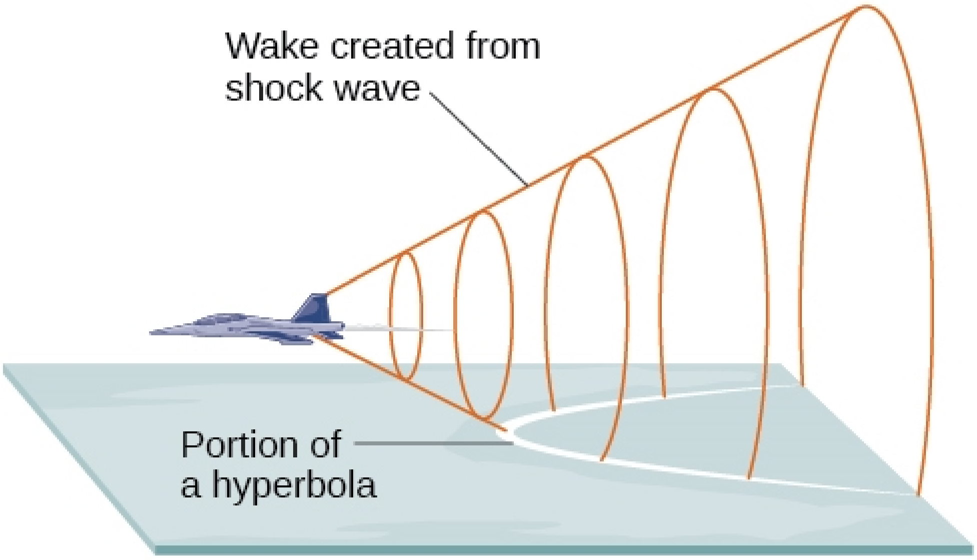
and possible real world neighbourhood noise impact analysis:



Wake created from shock wave
Portion of a hyperbola

Figure 8.150: **Shock wave intersecting the ground (source: OpenStax)**

The hyperbola of a sonic boom is described as a cone-shaped shock wave that intersects the ground in a hyperbolic curve. Every point on this curve is hit by the boom at the same time, allowing people in different locations to hear it simultaneously. This is because the hyperbolic curve moves forward as the airplane does, eventually allowing everyone in its path to hear the boom.

Remark

We also give the curve of equation $xy=1$ the name hyperbole because, with a variable change:

$$\begin{aligned} x &= X+Y \\ y &= X-Y \end{aligned} \tag{8.5.35}$$

Which brings us to:

$$X^2-Y^2=1 \tag{8.5.36}$$

which as we have seen, is the equation of a hyperbole.

For those who have Maple™ 4.00b or later here are some non-trivial commands to have fun to do a parabola:

```
>restart:  with(plots):
>c:=sqrt(x^2+y^2):
>p:=y+3:
>Y:=solve(c=p,y);
>intsect:=subs(y=Y,c);
>intsect := (x +(1/6*x-3/2))
>P1:=plot3d(c,x=-5..5,y=-5..5,axes=normal,color=red,numpoints=2000
,view=[-5..5,-5..5,0..5],style=wireframe):
>P2:=plot3d(p,x=-5..5,y=-5..5,axes=normal,color=yellow,
numpoints=2000,view=[-5..5,-5..5,0..5],style=patchnogrid):
>display(P1,P2,scaling=constrained, orientation=[-10,75]);
```

that gives:

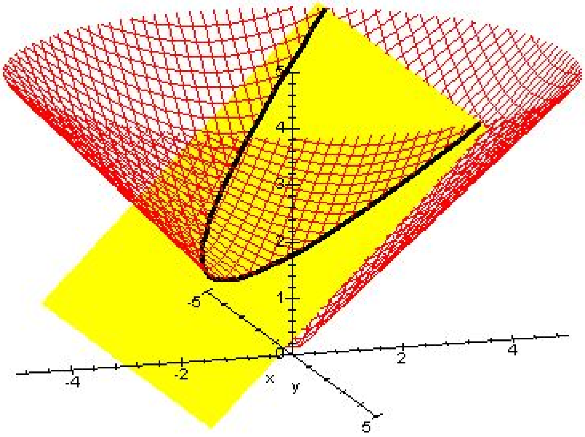


Figure 8.151: Maple™ 4.00b plot to obtain a parabola by the intersection of a cone and a plane

or to obtain a hyperbola:

```
>restart:  with(plots):
>c:=sqrt(x^2+y^2):
>p:=4*y+5:
>Y:=solve(c=p,y);
>intsect:=subs(y=Y[1],c);
>P1:=plot3d(c,x=-5..5,y=-5..5,axes=normal,color=red,numpoints=2000
,view=[-5..5,-5..5,0..5],style=wireframe):
>P2:=plot3d(p,x=-5..5,y=-5..5,axes=normal,color=yellow,numpoints=2000
,view=[-5..5,-5..5,0..5],style=patchnogrid):
>P3:=spacecurve([x,Y[1],intsect],x=-5..5,color=black,thickness=3):
```

```
P3:=spacecurve([x,Y[1],intsect],x=-5..5,color=black,thickness=3):
>display(P1,P2,P3,scaling=constrained);
```

that gives:

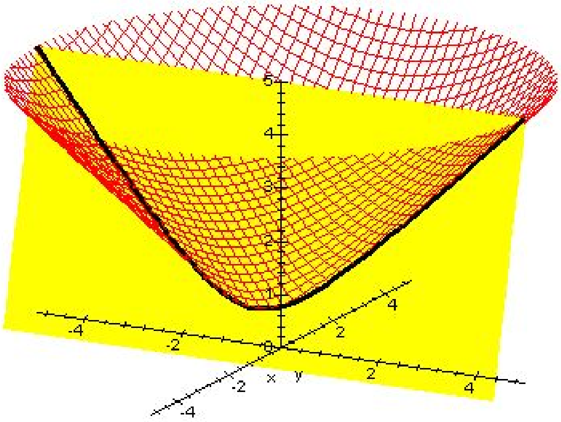

Figure 8.152: **Maple™ 4.00b plot to obtain a hyperparabola by the intersection of a cone and a plane**

or to obtain an ellipse:

```
>restart:  with(plots):
>c:=sqrt(x^2+y^2):
>p:=y/3+3:
>Y:=solve(c=p,y);
>E1:=subs(y=Y[1],c); E2:=subs(y=Y[2],c);
>P1:=plot3d(c,x=-5..5,y=-5..5,axes=normal,color=red,numpoints=2000,
view=[-5..5,-5..5,0..5],style=wireframe):
>P2:=plot3d(p,x=-5..5,y=-5..5,axes=normal,color=yellow,numpoints=2000,
view=[-5..5,-5..5,0..5],style=patchnogrid):
>P3:=spacecurve([x,Y[1],E1],[x,Y[2],E2],x=-5..5,color=black,thickness=3,
numpoints=2000):
>display(P1,P2,P3,scaling=constrained);
```

that gives:

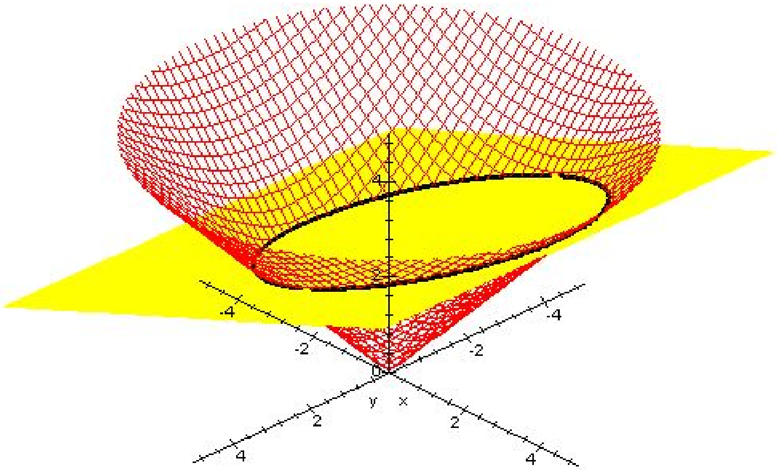

Figure 8.153: Maple™ 4.00b plot to obtain an ellipse by the intersection of a cone and a plane

or finally to obtain a circle:

```
>restart: with(plots):
>c:=sqrt(x^2+y^2):
>p:=3:
>Y:=solve(c=p,y);
>circ1:=subs(y=Y[1],c); circ2:=subs(y=Y[2],c);
>P1:=plot3d(c,x=-5..5,y=-5..5,axes=normal,color=red,numpoints=2000,
view=[-5..5,-5..5,0..5],style=wireframe):
>P2:=plot3d(p,x=-5..5,y=-5..5,axes=normal,color=yellow,numpoints=2000,
view=[-5..5,-5..5,0..5],style=patchnogrid):
>P3:=spacecurve([x,Y[1],circ1],[x,Y[2],circ2],
x=-5..5,color=black,thickness=3,numpoints=2000):
>display(P1,P2,P3);
```

that gives:

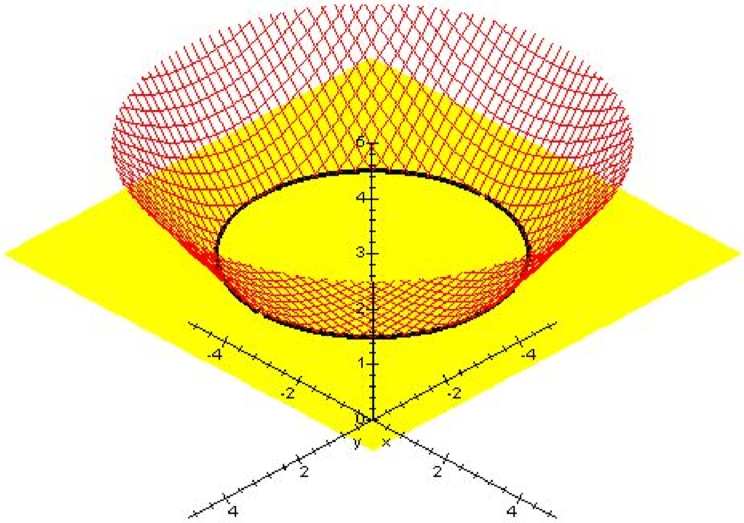

Figure 8.154: Maple™ 4.00b plot to obtain a circle by the intersection of a cone and a plane

However, the conicals also have a geometrical definition:

8.5.1.2 Geometric Approach

Let F be a point in the plane, D a line but not containing F (but to a non-zero distance of it) and e a positive real number. We are interested in the set of points M defined by:

$$\boxed{\{M|e\cdot d(M,D)=d(M,F)\}} \tag{8.5.37}$$

where F is named the "focus", D the "direction of the conical" and e the "eccentricity[10]":

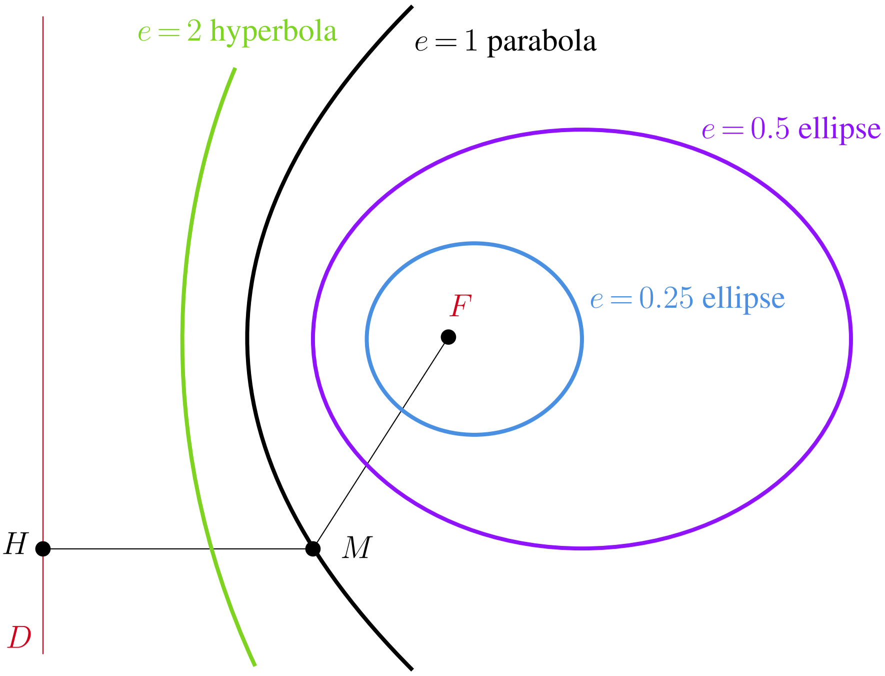

Figure 8.155: **Definition of the focus (F), direction (D) of the conical and eccentricity (e)**

We will arrange subsequently to have always F as the origin of the basis for the conical, therefore D will have by definition for equation:

$$x=-h \tag{8.5.38}$$

with $h>0$ so we therefore denote by $d(M,D)$ the distance between the point M and D.

Therefore:

$$\begin{aligned}&e\cdot d(M,D)=d(M,F)\\&\Leftrightarrow e|x+h|=\sqrt{x^2+y^2}\\&\Leftrightarrow e^2(x+h)^2=x^2+y^2\\&\Leftrightarrow (1-e^2)x^2+y^2-2e^2hx-e^2h^2=0\end{aligned} \tag{8.5.39}$$

We well fall back on the equation of a conic since the latter is a special case of:

$$\alpha x^2+\beta y^2+\delta x+\varepsilon y+\xi=0 \tag{8.5.40}$$

We can now consider several specific cases:

---

[10] The eccentricity of the Earth's orbit varies over time, due to gravitational interaction with other celestial bodies. The eccentricity value can get as low as 0.0034 and up to 0.058. Because of the eccentricity the orbit of the Earth from the farthest (aphelion) to nearest (perihelion) point of the Sun its distance has a differential of almost 3 millions kilometers actually.

1. Case where $e=1$:

   The equation:

   $$(1-e^2)x^2+y^2-2e^2hx-e^2h^2=0 \tag{8.5.41}$$

   then reduces trivially to:

   $$y^2-h^2=2hx \tag{8.5.42}$$

   It is therefore a parabola of axis orthogonal to D, whose top Ω is the mid-segment $\overline{FK}$, where K is the projection of F on D (see figure below).

   If we rewrite the last relation in the form:

   $$y^2=2hx+h^2=2h\left(x+\frac{h}{2}\right) \tag{8.5.43}$$

   and redefining the origin with respect to Ω by a translation of $h/2$, the generating focus of the parabola will be in $F=(h/2,0)$ and the latter equation is then reduced to:

   $$y^2=2hx \tag{8.5.44}$$

   where h is named "parameter of the parabola" and relatively to Ω, the focus will be given by the coordinates $F=(h/2,0)$ and the direction (directrix) by the equation $D:x=-h/2$. Written in a different way we fall back on the famous relation of the parabola in functional analysis (the reader can refer to a practical calculation example for an antenna in the section about Optics):

   $$x=\frac{1}{2h}y^2 \tag{8.5.45}$$

   That is:

   $$\boxed{x\propto y^2} \tag{8.5.46}$$

   As shown in the figure below, the distance to the direction to Ω is imposed by the conditions of the model:

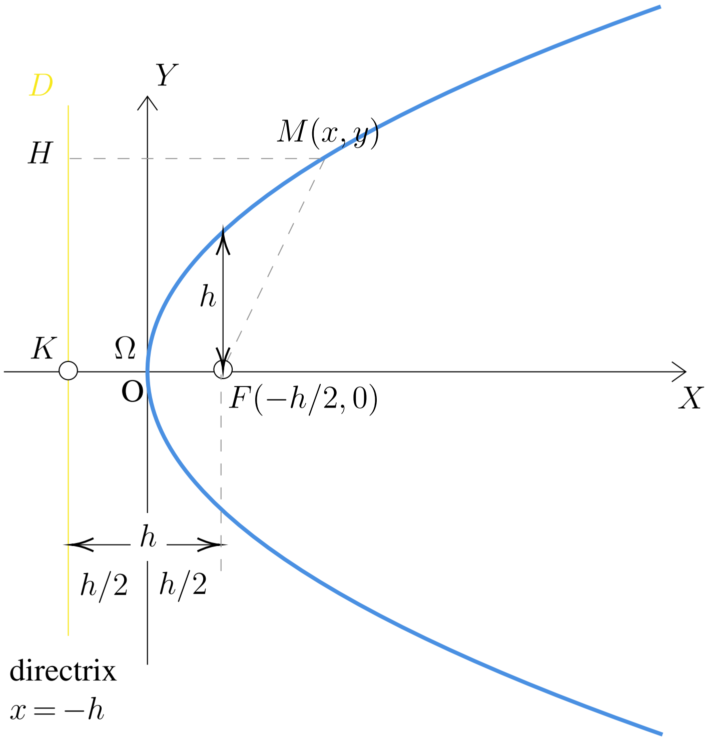

Figure 8.156: **Representation of the parameters of the conical for the parabola**

Based on the feedback of a reader let us introduce the parabola in another way that seems for some people more intuitive and more pedagogical (take from [309]).

We want to introduce the equation:

$$y = ax^2 + bx + c \tag{8.5.47}$$

which is a U-shaped curve named a "vertical parabola". We begin with the general definition of a parabola in the plane.

If we are given a line L and a point F not on L, the set of all points equidistant from L and F will form a U-shaped curve that passes midway between L and F and named a "parabola":

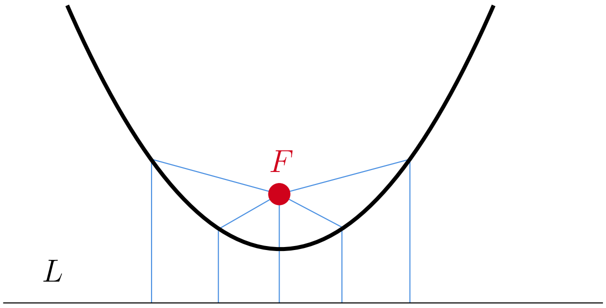

Figure 8.157: **Parabola = set of points equidistant from L and F**

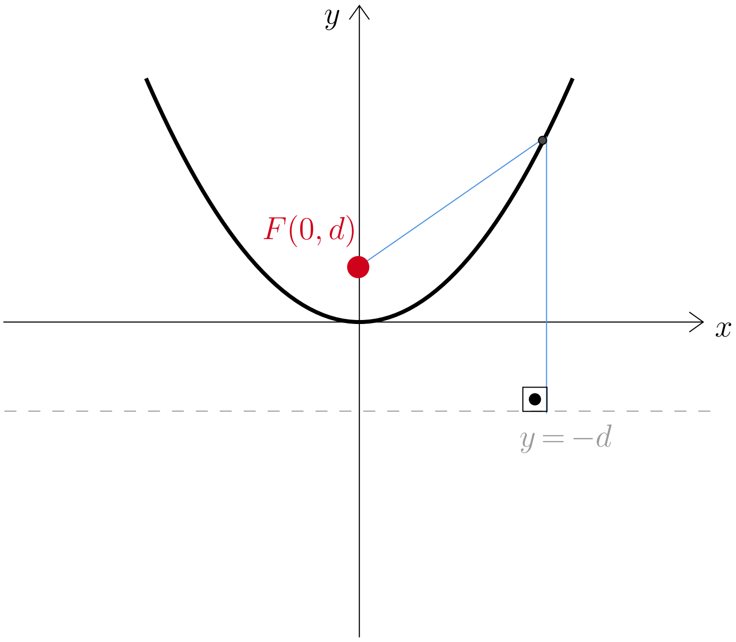
Theorem 8.20. The graph of the equation:

$$y = ax^2 \tag{8.5.48}$$

(where $a \neq 0$) is the parabola with focus $F\left(0, \frac{1}{4}a\right)$ and directrix $y = -\left(\frac{1}{4}a\right)$. Its vertex is (0.0) and it axis is the y-axis.

Proof 8.20.1. Let us find the equation of the parabola with focus $F(0,d)$ and directrix $y=-d$, as shown below where obviously $d={}^1\!/\!_{4a}$:



Our plan is to show that the equation is $y=ax^2$ where $d={}^1\!/\!_{4a}$. Given a point $P(x,y)$, the perpendicular from P to the directrix is a vertical line of length $y+d$. Thus:

$$\begin{aligned}\text{distance from } P \text{ to directrix} &= y+d\\ \text{distance from } P \text{ to focus} &= \sqrt{x^2+(y-d)^2}\end{aligned} \tag{8.5.49}$$

The point P lies on the parabola exactly when these distances are equal:

$$y+d=\sqrt{x^2+(y-d)^2} \tag{8.5.50}$$

Simplifying we get:

$$\begin{aligned}(y+d)^2&=x^2+(y-d)^2\\ y^2+2yd+d^2&=x^2+y^2-2yd+d^2\end{aligned} \tag{8.5.51}$$

Therefore:

$$y=\frac{1}{4d}x^2=ax^2 \tag{8.5.52}$$

■ Q.E.D.

2. Case where $e<1$:

   It is an ellipse. Indeed it is not easy to see it but by rearranging the terms of equation:

$$(1-e^2)x^2+y^2-2e^2hx-e^2h^2=0 \tag{8.5.53}$$

we have (and this independently of whether $e<1$ or not):

$$(1-e^2)\left(x-\frac{e^2h}{1-e^2}\right)^2+y^2-\frac{e^2h^2}{1-e^2}=0\Leftrightarrow\frac{\left(x-\dfrac{e^2h}{1-e^2}\right)}{\dfrac{e^2h^2}{(1-e^2)^2}}+\frac{y^2}{\dfrac{e^2h^2}{1-e^2}}=1 \tag{8.5.54}$$

The last term of the ante-previous relation can recovered as following after development:

$$\frac{e^4h^2}{1-e^2}-\frac{e^2h^2}{1-e^2}=e^2h^2\left(\frac{e^2-1}{1-e^2}\right)=-e^2h^2 \tag{8.5.55}$$

Let us define:

$$F=\frac{e^2h}{1-e^2} \tag{8.5.56}$$

is the origin of the ellipse on X (then the x and y must now be taken relative to this new origin!!!). The previous equation can therefore be simplified and becomes (this always regardless of whether $e<1$ or not):

$$\boxed{\frac{x^2}{\dfrac{e^2h^2}{(1-e^2)^2}}+\frac{y^2}{\dfrac{e^2h^2}{1-e^2}}=\frac{x^2}{a^2}+\frac{y^2}{b^2}=1} \tag{8.5.57}$$

Therefore if $e<1$, the denominators are both positive and we fall back on the reduced equation of an ellipse since $a\neq b$.

Remark

You must notice that this definition can not include the circle among the ellipses otherwise there is a singularity because the denominators would be zero (the eccentricity being equal to zero for the circle).

To get the semi-major axis of the ellipse we just have to put $y=0$. Thus, we have:

$$\frac{x^2}{\dfrac{e^2h^2}{(1-e^2)^2}}=\frac{x^2}{a^2}=1 \tag{8.5.58}$$

then the semi-major axis is equal to:

$$a=\pm\frac{eh}{1-e^2}=\pm\frac{F}{e} \tag{8.5.59}$$

in the same way, we get for the semi-minor axis:

$$b=\pm\frac{eh}{\sqrt{1-e^2}} \tag{8.5.60}$$

putting $p=eh$ being the "parameter of the ellipse" or "focal parameter of the ellipse", we get:

$$\boxed{|a|=\frac{p}{1-e^2}\qquad |b|=\frac{p}{\sqrt{1-e^2}}} \tag{8.5.61}$$

whose first relation will be very useful in the section of Astronomy and also in the section of General Relativity.

Notice also by the way that we have then:

$$\frac{b^2}{a}=\frac{\dfrac{p^2}{(\sqrt{1-e^2})^2}}{\dfrac{p}{1-e^2}}=p \tag{8.5.62}$$

It is customary to denote the distance from the center Ω of the ellipse to the foci point F with the letter c such that:

$$c=\overline{\Omega F}=F \tag{8.5.63}$$

We then have:

$$c=F=\pm ae\Leftrightarrow e=\pm\frac{c}{a} \tag{8.5.64}$$

There are therefore two foci to the ellipse at a distance equivalent but opposite of the center Ω. We define therefore the eccentricity of an ellipse by the ratio:

$$e=\frac{c}{a}=\frac{\overline{\Omega F}}{a} \tag{8.5.65}$$

The reader will perhaps also noticed that we for $x=0$ in:

$$(1-e^2)x^2+y^2-2e^2hx-e^2h^2=0 \tag{8.5.66}$$

the ordinate that is therefore given by the product eh and it can be expressed by the ellipse parameters under the form (even if this may seem odd at units level this is implicitly correct):

$$p=eh=b \tag{8.5.67}$$

We can then also prove a relation that is very common in formula compilation hanbooks about ellipses:

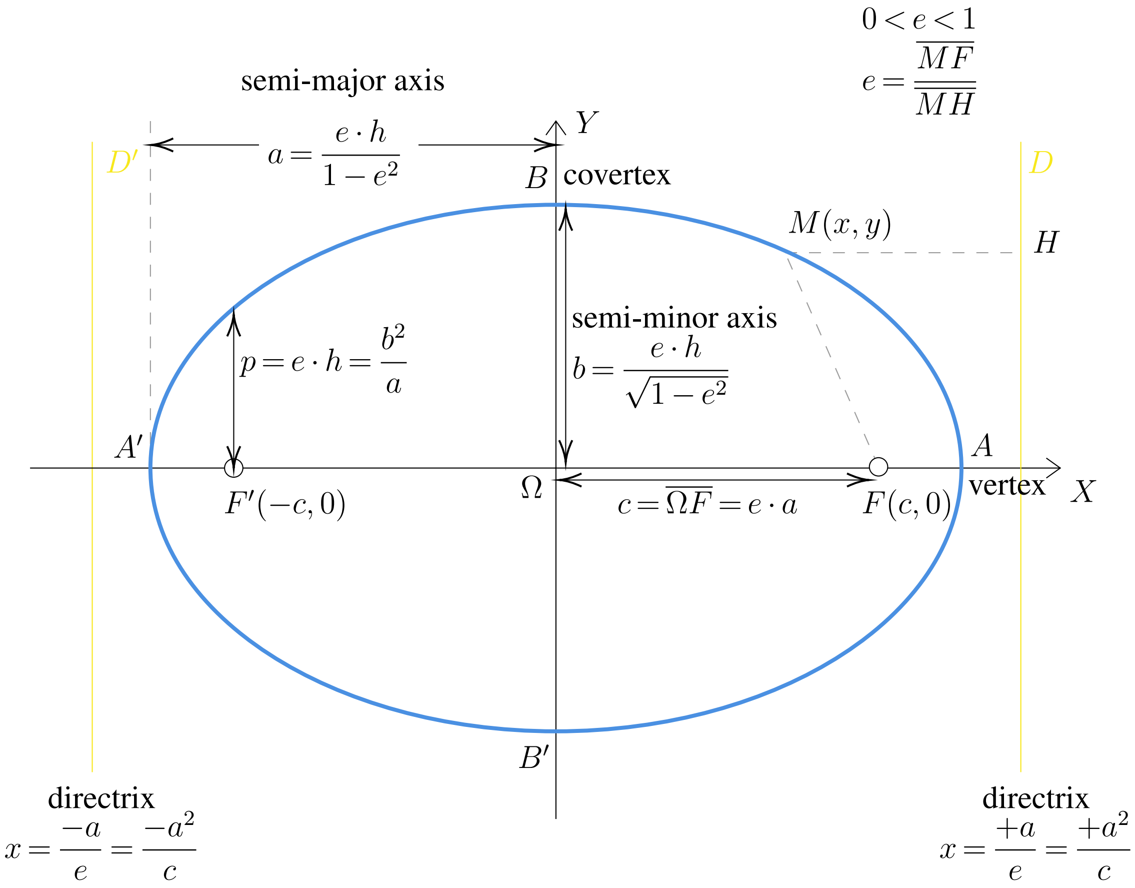
$$a^2=b^2+c^2 \tag{8.5.68}$$

That is to say:

$$\frac{e^2h^2}{(1-e^2)^2}=\frac{e^2h^2}{1-e^2}+e^2a^2=\frac{e^2h^2}{1-e^2}+e^2\frac{e^2h^2}{(1-e^2)^2}=\frac{e^2h^2(1-e^2)+e^4h^2}{(1-e^2)^2}=\frac{e^2h^2}{(1-e^2)^2} \tag{8.5.69}$$

This property is then proved and that brings us to be able to write the eccentricity only thanks to the conventional parameters of the ellipse:

$$\boxed{e=\frac{c}{a}=\frac{\sqrt{a^2-b^2}}{a}} \tag{8.5.70}$$



$0<e<1$
$e=\frac{\overline{MF}}{\overline{MH}}$

$x=\frac{+a}{e}=\frac{+a^2}{c}$

Figure 8.158: Representation of the parameters of the conical for the ellipse

The distance from the center of the ellipse to each focus is $c=ae$. The distance from the center to a vertex is a. Therefore, the distance from a focus to the closer vertex is the difference between these distances, $a-c$, which can be expressed in terms of a and e as:

$$f=a-c=a-ae=a(1-e) \tag{8.5.71}$$

The distance from a focus to the farther vertex is $a+c$ or $a(1+e)$.

Here are some well known elliptic eccentricities (the reader must keep in mind that these are not constants!):

Celestial object orbit	Orbit eccentricity e
Mercury	0.206
Venus	0.007
Earth	0.017
Mars	0.093
Jupiter	0.048
Saturn	0.056
Uranus	0.047
Neptun	0.09
Pluton	0.250
Hubble Telescope	0.0002842
International Space Station	0.0005309
Halley's comet	0.970

Table 8.5: Some elliptic eccentricity values

We can also find out where are the director lines D of the ellipse with respect to the edge of this latter by using the definition of eccentricity when $y=0$. Then we have:

$$\begin{aligned} &e\cdot d(M,D)=d(M,F)\\ &\Leftrightarrow d(M,D)=\frac{d(M,F)}{e}=\frac{a-ea}{e}=a\frac{1-e}{e} \end{aligned} \tag{8.5.72}$$

therefore the factor of a is between 0 and $+\infty$ and this has for meaning that the director lines will be situated (at least in the special case presented here where the eccentricity is positive and strictly less than the unit) always outside of the ellipse border and in the nearest case tangential to this same border (but in all cases they will be outside of the ellipse).

A useful and obvious parametric representation of the ellipse is an extension of the trigonometric circle (see section Trigonometry page 2511):

$$\begin{aligned} x&=a\cos(t)\\ y&=b\sin(t) \end{aligned} \tag{8.5.73}$$

Indeed, if we consider the Cartesian equation of the ellipse proved above:

$$\frac{X^2}{a^2}+\frac{Y^2}{b^2}=1 \tag{8.5.74}$$

and putting $R=X/a$ and $S=Y/b$ we get:

$$R^2+S^2=1 \tag{8.5.75}$$

If we remember the unit circle in trigonometry, this equation admits as solutions $R=\cos(t)$ and $S=\sin(t)$. It comes then:

$$\begin{aligned} R&=\frac{X}{a}=\cos(t)\Rightarrow X=a\cos(t)\\ S&=\frac{Y}{b}=\sin(t)\Rightarrow Y=b\sin(t) \end{aligned} \tag{8.5.76}$$

That's it! And obviously if $a=b\neq 0$ we fall back on the parametric equation of a circle!

Now let us prove an important property of ellipses: The sum of the distance of the two foci to a point M on the border of the ellipse is constant and equal to the major axis.

Proof 8.20.2. We consider the center is the midpoint of the foci of coordinate $\Omega(0,0)$. The foci lie on the major axis $y=0$ and same for the equation of the minor axis for which $x=0$.

Now, if the length of the major, minor axes are $2a, 2b$ respectively with eccentricity e the equation of the ellipse is:

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1 \tag{8.5.77}$$

Any point M on the ellipse can be described as we have just seen before by:

$$M(a\cos(\theta),b\sin(\theta)) \tag{8.5.78}$$

So, the distance between a point $M(a\cos(\theta), b\sin(\theta))$ and one of the foci of coordinate $(ae, 0)$ is :

$$\begin{aligned}\overline{MF} &= \sqrt{(ae-a\cos(\theta)^2+(b\sin(\theta)-0)^2} = \sqrt{a^2e^2+a^2\cos^2(\theta)-2a^2e\cos(\theta)+b^2\sin^2(\theta)}\\ &= \sqrt{a^2e^2+a^2\cos^2(\theta)-2a^2e\cos(\theta)+b^2(1-\cos^2(\theta))}\\ &= \sqrt{a^2e^2+a^2\cos^2(\theta)-2a^2e\cos(\theta)+a^2(1-e^2)(1-\cos^2(\theta))}\\ &= \sqrt{a^2e^2+a^2\cos^2(\theta)-2a^2e\cos(\theta)+(a^2-a^2e^2)(1-\cos^2(\theta))}\\ &= \sqrt{a^2e^2+a^2\cos^2(\theta)-2a^2e\cos(\theta)+a^2-a^2e^2-a^2\cos^2(\theta)+a^2e^2\cos^2(\theta)}\\ &= \sqrt{-2a^2e\cos(\theta)+a^2+a^2e^2\cos^2(\theta)}\\ &= a\sqrt{-2e\cos(\theta)+1+e^2\cos^2(\theta)}\\ &= a\sqrt{(1-e\cos(\theta))^2} = a(1-e\cos(\theta))\end{aligned} \tag{8.5.79}$$

Similarly (as always you can request the details if necessary), the distance between $(a\cos(\theta), b\sin(\theta)), (-ae, 0)$ is equal to $a(1+e\cos(\theta))$.

Therefore the sum gives:

$$a(1-e\cos(\theta))+a(1+e\cos(\theta)) = 2a \tag{8.5.80}$$

■ Q.E.D.

It is this result that authorizes us to say that an ellipse can be constructed in the famous following way:

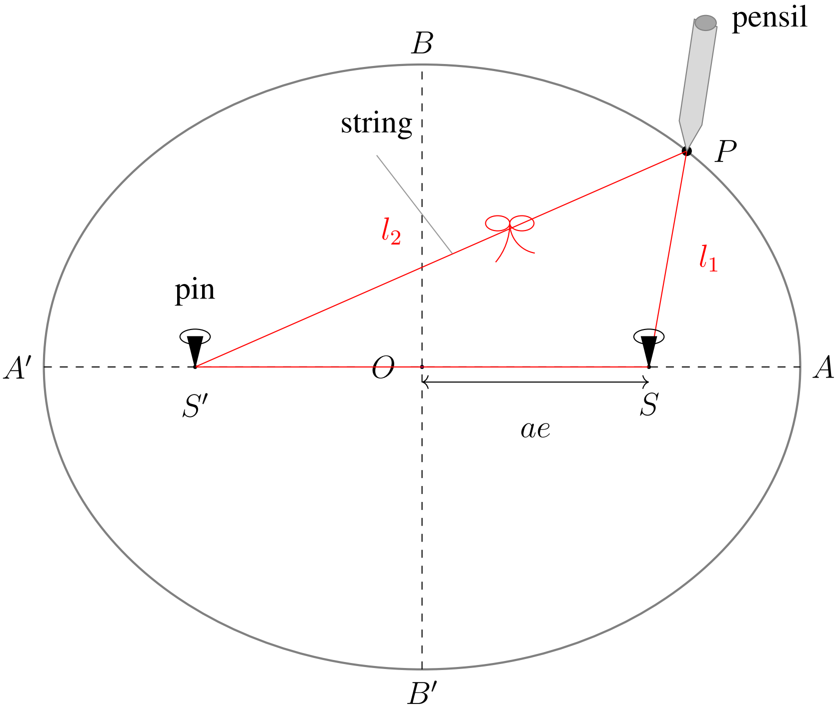

Figure 8.159: **Hand-made construction of an ellipse (author: Ridlo W. Wibowo)**

It is interesting also to see the opposite reasoning! We suppose the construction above as a definition and we build from it the equation of the ellipse centered at the origin!

For this we begin with the foci $(-c,0)$ and $(c,0)$. The ellipse is then by definition the set of all points (x,y) such that the sum of the distances from (x,y) to the foci is constant, as shown in the figure above.

If $(a,0)$ is a vertex of the ellipse, the distance from $(-c,0)$ to $(a,0)$ is:

$$a-(-c)=a+c \tag{8.5.81}$$

The distance from $(c,0)$ to $(a,0)$ is $a-c$. The sum of the distances from the foci to the vertex is:

$$(a+c)+(a-c)=2a \tag{8.5.82}$$

If (x,y) is a point on the ellipse, then we can define the following variables:

$$\begin{aligned}d_1 &= \text{the distance from } (-c,0) \text{ to } (x,y)\\ d_2 &= \text{the distance from } (c,0) \text{ to } (x,y)\end{aligned} \tag{8.5.83}$$

By the definition of an ellipse, the sum of distances d_1, d_2 of the foci to any point (x,y) of the ellipse is equal to and is constant! We know that the sum of these distances is $2a$ for the vertex $(a,0)$. It follows that:

$$d_1+d_2=2a \tag{8.5.84}$$

for any point on the ellipse. We will begin the derivation by applying the distance formula. The rest of the derivation is algebraic:

$$\begin{aligned}
& d_1+d_2=\sqrt{(x-(-c))^2+(y-0)^2}+\sqrt{(x-c)^2+(y-0)^2}=2a && \text{Distance formula}\\
& \sqrt{(x+c)^2+y^2}+\sqrt{(x-c)^2+y^2}=2a && \text{Simplify expressions}\\
& \sqrt{(x+c)^2+y^2}=2a-\sqrt{(x-c)^2+y^2} && \text{Move radical to opposite side}\\
& (x+c)^2+y^2=\left[2a-\sqrt{(x-c)^2+y^2}\right]^2 && \text{Square both sides}\\
& x^2+2cx+c^2+y^2=4a^2-4a\sqrt{(x-c)^2+y^2}+(x-c)^2+y^2 && \text{Expand the squares}\\
& x^2+2cx+c^2+y^2=4a^2-4a\sqrt{(x-c)^2+y^2}+x^2-2cx+c^2+y^2 && \text{Expand remaining squares}\\
& 2cx=4a^2-4a\sqrt{(x-c)^2+y^2}-2cx && \text{Combine like terms}\\
& 4cx-4a^2=-4a\sqrt{(x-c)^2+y^2} && \text{Isolate the radical}\\
& cx-a^2=-a\sqrt{(x-c)^2+y^2} && \text{Divide by 4}\\
& [cx-a^2]^2=a^2\left[\sqrt{(x-c)^2+y^2}\right]^2 && \text{Square both sides}\\
& c^2x^2-2a^2cx+a^4=a^2\left(x^2-2cx+c^2+y^2\right) && \text{Expand the squares}\\
& c^2x^2-2a^2cx+a^4=a^2x^2-2a^2cx+a^2c^2+a^2y^2 && \text{Distribute } a^2\\
& a^2x^2-c^2x^2+a^2y^2=a^4-a^2c^2 && \text{Rewrite}\\
& x^2\left(a^2-c^2\right)+a^2y^2=a^2\left(a^2-c^2\right) && \text{Factor common terms}\\
& x^2b^2+a^2y^2=a^2b^2 && \text{Set } b^2=a^2-c^2\\
& \tfrac{x^2b^2}{a^2b^2}+\tfrac{a^2y^2}{a^2b^2}=\tfrac{a^2b^2}{a^2b^2} && \text{Divide both sides by } a^2b^2\\
& \tfrac{x^2}{a^2}+\tfrac{y^2}{b^2}=1 && \text{Simplify}
\end{aligned} \tag{8.5.85}$$

Thus, the standard equation of an ellipse is:

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1 \tag{8.5.86}$$

The equation defines an ellipse centered at the origin, with for recall:

- If $a > b$, the ellipse is stretched further in the horizontal direction
- If $b > a$, the ellipse is stretched further in the vertical direction
- The length of the major axis is $2a$
- The coordinates of the vertices are $(0, \pm a)$
- The length of the minor axis is $2b$
- The coordinates of the co-vertices are $(\pm b, 0)$
- The coordinates of the foci are $(0, \pm c)$
- We have the identity $c^2 = a^2 - b^2$

The standard form of the equation of an ellipse with center (h, k) is then obviously:

$$\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1 \tag{8.5.87}$$

However, there is another form of the equation of the ellipse, much more important, which is found in the sections of mechanics, astrophysics and quantum physics of this textbook.

First let us recall that:

$$e \cdot d(M, D) = d(M, F) \Leftrightarrow e|x+h| = \sqrt{x^2 + y^2} \tag{8.5.88}$$

In polar coordinates, this gives:

$$e \cdot d(M, D) = d(M, F) \Leftrightarrow e|r\cos(\theta) + h| = r \tag{8.5.89}$$

Therefore:

$$r = e(r\cos(\theta) - h) \quad \text{or} \quad r = -e(r\cos(\theta) - h) \tag{8.5.90}$$

after identification:

$$r_1 = \frac{-eh}{1 - e\cos(\theta)} \qquad r_2 = \frac{eh}{1 + e\cos(\theta)} \tag{8.5.91}$$

We obtain two different equations, but it is actually the same curve that describes the radius of the ellipse from one of its two foci. And we can see that:

$$r_1(\theta + \pi) = -r_2(\theta) \tag{8.5.92}$$

Since the $p = eh$ is defined as the parameter of the conical, the polar equation of the ellipse is given by:

$$r = \frac{p}{1 + e\cos(\theta)} \tag{8.5.93}$$

where θ is named the "true anomaly".

Notice the three special values:

$$\begin{aligned} &\theta = \frac{\pi}{2} \Rightarrow r = p = eh : \text{focal parameter} \\ &\theta = 0 \Rightarrow r_p = \frac{p}{1+e} : \text{pericenter (perihelion)} \\ &\theta = \pi \Rightarrow r_a = \frac{p}{1-e} : \text{apocenter (aphelion)} \end{aligned} \tag{8.5.94}$$

and we get obviously:

$$a=\frac{r_a+r_p}{2} \qquad \text{and} \qquad c=\frac{r_a-r_p}{2} \tag{8.5.95}$$

and since $e=\pm c/a$ we get also another famous relation for eccentricity:

$$e=\pm\frac{\dfrac{r_a-r_p}{2}}{\dfrac{r_a+r_p}{2}}=\pm\frac{r_a-r_p}{r_a+r_p} \tag{8.5.96}$$

The pericenter is better known as the "perigee" in astronomy as well as the apocenter which is better known as the "apogee" and are used a lot in astronomy and astrodynamics.

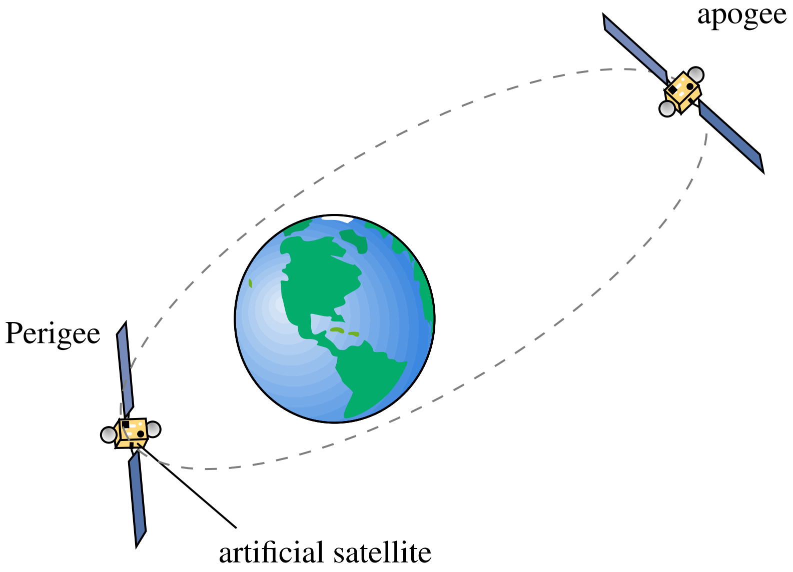

Figure 8.160: **Apogee and Perigee**

Remark

In facts, "apogee" and "perigee" are reserved words when the Earth is on the foci. If it is the Sun (actually a G2V-type star, aka yellow dwarf) that is the foci we then speak of "aphelion" (corresponding approximately to the beginning of Winter) and "perihelion" (corresponding approximately to the beginning of Summer).

In the general case, D may do any angle with the axis of polar angles, and the general equation is then (very important relation in astronomy and aerospace engineering!):

$$\boxed{r=\frac{p}{1+e\cos(\theta-\theta_0)}=\frac{a(1-e^2)}{1+e\cos(\theta-\theta_0)}=\frac{a\left(1-\left(\dfrac{c}{a}\right)^2\right)}{1+\left(\dfrac{c}{a}\right)\cos(\theta-\theta_0)}} \tag{8.5.97}$$

Let us prove now the interesting result that a special kind of parabola is an ellipse, but with one focal point at infinity!

Let us choose the equation for an ellipse with a focus at $(0,0)$ and the other at $(0,2ae)$ keeping $a(1-e)=f$ (where for reminder f is distance from the vertex to the focus of the ellipse, which ends up being the focal length of the parabola) such that:

$$\frac{x^2}{a^2\left(1-e^2\right)}+\frac{(y-ae)^2}{a^2}=1 \tag{8.5.98}$$

which is equivalent to:

$$\frac{x^2}{f(1+e)}+\frac{y^2-2aey}{a}=f(1+e) \tag{8.5.99}$$

If we let $a\rightarrow+\infty$ (and therefore $e=1-\frac{f}{a}\rightarrow 1$), we get:

$$\frac{x^2}{2f}-2y=2f \tag{8.5.100}$$

Hence:

$$y=\frac{x^2}{4f}-f \tag{8.5.101}$$

which is a parabola! This results explains why in ballistics when we take into account Earth's curvature (see section Classical Mechanics page 3278) the trajectory in the low speed regime is almost a parabola because Earth's radius is huge!

3. Case where $e>1$:

   This is a hyperbola (same reasoning as the ellipse considering by starting with any other value than $e>1$ or not):

$$\left(1-e^2\right)\left(x-\frac{e^2h}{1-e^2}\right)^2+y^2-\frac{e^2h^2}{1-e^2}=0\Leftrightarrow\frac{\left(x-\dfrac{e^2h}{1-e^2}\right)}{\dfrac{e^2h^2}{(1-e^2)^2}}+\frac{y^2}{\dfrac{e^2h^2}{1-e^2}}=1 \tag{8.5.102}$$

   Where we put again:

$$F=\frac{e^2h}{1-e^2} \tag{8.5.103}$$

   is the origin of hyperbole. The above equation is simplified and becomes (so far, we end up with exactly the same expression as for the ellipse):

$$\frac{x^2}{\dfrac{e^2h^2}{(1-e^2)^2}}+\frac{y^2}{\dfrac{e^2h^2}{1-e^2}}=\frac{x^2}{a^2}+\frac{y^2}{b^2}=1 \tag{8.5.104}$$

   But as $e>1$ the denominator of the second term will be negative and therefore we fall back on the reduced equation of a hyperbole!

   We have therefore for semi-major axis and semi-minor axis (same reasoning as for the ellipse):

$$|a|=\frac{p}{1-e^2}\qquad |b|=\frac{p}{\sqrt{1-e^2}} \tag{8.5.105}$$

and:

$$e=\frac{c}{a}=\frac{\sqrt{a^2+b^2}}{a} \tag{8.5.106}$$

with the corresponding figure:

directrix
$x=a\cdot e=a\cdot 2c$

Figure 8.161: **Representation of the parameters of the conical for the hyperbola**

where we presented the two asymptotes using a simple technique of passing to the limit:

$$\frac{x^2}{a^2}-\frac{y^2}{b^2}=1\Leftrightarrow y=\sqrt{\frac{b^2}{a^2}x^2-b^2}\underset{x\to+\infty}{\cong}\sqrt{\frac{b^2}{a^2}x^2}=\pm\frac{b}{a}x=\triangle \tag{8.5.107}$$

If the hyperbole is equilateral, then it is obvious that the two asymptotes are perpendiculars since their slope is then respectively $+1$ and -1. In the equilateral case, we also have the eccentricity which is immediately given by:

$$e=\sqrt{\frac{a^2+b^2}{a}}=\frac{\sqrt{a^2+a^2}}{a}=\sqrt{2} \tag{8.5.108}$$

We can also determine where are the director lines D of the hyperbolas with respect to their border by using the definition of the eccentricity when $y=0$ by performing exactly in the same as for the ellipse. Then we have:

$$ed(M,D)=d(M,F)\quad\Leftrightarrow d(M,D)=\frac{d(M,F)}{e}=\frac{ea-e}{e}=a\frac{e-1}{e} \tag{8.5.109}$$

therefore the factor of a is between 0 and tend to 1 as e is very large meaning that the director lines will be located (at least in the case here where this eccentricity is positive and strictly smaller than unity) is tangential to the hyperbola that is to say the closest to the y-axis (but in all cases they will therefore be between the two hyperbolas).

There is another nice way to build the equation of the hyperbola by assuming that he hyperbola is the set of all points (x,y) such that the difference of the distances d_1, d_2 from (x,y) to the foci is constant (so keep in mind that the ellipse is defined by the sum of distance, whereas the hyperboloid is defined by the difference).

For this proof let us consider $(-c,0)$ and $(c,0)$ be the foci of a hyperbola centered at the origin.

If $(a,0)$ is a vertex of the hyperbola, the distance from $(-c,0)$ to $(a,0)$ is:

$$a-(-c)=a+c \tag{8.5.110}$$

The distance from $(c,0)$ to $(a,0)$ is $c-a$. The sum of the distances from the foci to the vertex is:

$$(a+c)-(c-a)=2a \tag{8.5.111}$$

If (x,y) is a point on the hyperbola, we can define the following variables:

$$\begin{aligned}d_2&=\text{the distance from } (-c,0) \text{ to } (x,y)\\ d_1&=\text{the distance from } (c,0) \text{ to } (x,y)\end{aligned} \tag{8.5.112}$$

By assuming that for a hyperbola, d_2-d_1 is constant for any point (x,y) on the hyperbola it follows for the vertex $(a,0)$ that:

$$d_2-d_1=2a \tag{8.5.113}$$

and therefore the same value should be consistent for the whole hyperbola. As with the derivation of the equation of an ellipse seen just previously, we will begin by applying the distance formula. The rest of the derivation is algebraic. Compare this derivation with the one from the previous section for ellipses:

$$\begin{aligned}
& d_2-d_1=\sqrt{(x-(-c))^2+(y-0)^2}-\sqrt{(x-c)^2+(y-0)^2}=2a && \text{Distance Formula}\\
& \sqrt{(x+c)^2+y^2}-\sqrt{(x-c)^2+y^2}=2a && \text{Simplify expressions}\\
& \sqrt{(x+c)^2+y^2}=2a+\sqrt{(x-c)^2+y^2} && \text{Move radical to opposite side}\\
& (x+c)^2+y^2=\left(2a+\sqrt{(x-c)^2+y^2}\right)^2 && \text{Square both sides}\\
& x^2+2cx+c^2+y^2=4a^2+4a\sqrt{(x-c)^2+y^2}+(x-c)^2+y^2 && \text{Expand the squares}\\
& x^2+2cx+c^2+y^2=4a^2+4a\sqrt{(x-c)^2+y^2}+x^2-2cx+c^2+y^2 && \text{Expand remaining square}\\
& 2cx=4a^2+4a\sqrt{(x-c)^2+y^2}-2cx && \text{Combine like terms}\\
& 4cx-4a^2=4a\sqrt{(x-c)^2+y^2} && \text{Isolate the radical}\\
& cx-a^2=a\sqrt{(x-c)^2+y^2} && \text{Divide by 4}\\
& (cx-a^2)^2=a^2\left[\sqrt{(x-c)^2+y^2}\right]^2 && \text{Square both sides}\\
& c^2x^2-2a^2cx+a^4=a^2\left(x^2-2cx+c^2+y^2\right) && \text{Expand the squares}\\
& c^2x^2-2a^2cx+a^4=a^2x^2-2a^2cx+a^2c^2+a^2y^2 && \text{Distribute } a^2\\
& a^4+c^2x^2=a^2x^2+a^2c^2+a^2y^2 && \text{Combine like terms}\\
& c^2x^2-a^2x^2-a^2y^2=a^2c^2-a^4 && \text{Rearrange terms}\\
& x^2\left(c^2-a^2\right)-a^2y^2=a^2\left(c^2-a^2\right) && \text{Factor common terms}\\
& x^2b^2-a^2y^2=a^2b^2 && \text{Set } b^2=c^2-a^2.\\
& \tfrac{x^2b^2}{a^2b^2}-\tfrac{a^2y^2}{a^2b^2}=\tfrac{a^2b^2}{a^2b^2} && \text{Divide both sides by } a^2b^2\\
& \tfrac{x^2}{a^2}-\tfrac{y^2}{b^2}=1
\end{aligned} \tag{8.5.114}$$

This equation defines a hyperbola centered at the origin with vertices $(\pm a,0)$ and co-vertices $(0,\pm b)$.

Therefore the standard form of the equation of a hyperbola with center $(0,0)$ and transverse axis on the x-axis is:

$$\frac{x^2}{a^2}-\frac{y^2}{b^2}=1 \tag{8.5.115}$$

where:

- The length of the transverse axis is $2a$
- The coordinates of the vertices are $(\pm a,0)$
- The length of the conjugate axis is $2b$
- The coordinates of the co-vertices are $(0,\pm b)$
- The distances between the foci is $2c$
- We have the identity $c^2=a^2+b^2$
- The coordinates of the foci are $(\pm c,0)$

- The equations of the asymptotes are $y=\pm{}^{b}/_{a}$

And for the standard form equation of a hyperbola with center (h,k) and transverse axis parallel to the x-axis we have:

$$\frac{(x-h)^2}{a^2}-\frac{(y-k)^2}{b^2}=1 \tag{8.5.116}$$

Remember now that in the figure above we have represented the hyperbola:

$$\frac{x^2}{a^2}-\frac{y^2}{b^2}=1 \tag{8.5.117}$$

for some $0<a<b$. The asymptotes $y/b=\pm x/a$ have also been shown, and it is easy to see algebraically that the asymptotes indeed must be these equations.

The rectangle visible in the figure between the both hyperbolas is drawn such that the horizontal width is the distance $2a$, thus opposite sides are tangent to the vertices of the hyperbola at $(\pm a,0)$. The vertical height of the rectangle is chosen such that the rectangle's vertices are on the asymptotes, thus the height is $2b$ and the rectangle's vertices are $(\pm a,\pm b)$ where the signs can be chosen independently.

The red circle is simply the circumscribing circle to the rectangle. The intersection of this circle with the x-axis is the location of the hyperbola's foci, at $(\pm c,0)$. It is natural to see, then, that:

$$c^2=a^2+b^2 \tag{8.5.118}$$

from our description of the rectangle's vertices and the Pythagorean relationship that relates the rectangle's width and height to the circumradius.

The question, then, is why the focus happens to be located at the point of intersection of this circle with the coordinate axis? The reason is that the definition of the hyperbola is the locus of all points whose absolute difference of distances from the foci is constant. So for such a choice of c, it is fairly easy (though tedious) to show that points (x,y) satisfying the above equation for the hyperbola will have an absolute difference of distances from $(\pm c,0)$ a constant.

Remark

The reader can refer to the previous proof where we have derived:

$$\frac{x^2}{a^2}-\frac{y^2}{b^2}=1 \tag{8.5.119}$$

in the prior-previous line before the final result it is clearly written : "*Set* $b^2=c^2-a^2$". Because that's how things need to be done to get the final equation of the hyperbola!

Let us now still consider the hyperbola of equation:

$$\frac{x^2}{a^2}-\frac{y^2}{b^2}=1 \tag{8.5.120}$$

for an important result that we will also use during our study of gravitational assistance in the section of Aerospace Engineering.

For such an hyperbola where the center is at the origin $(0,0)$, the distance, c, from the center to each focus is:

$$c^2=a^2+b^2 \tag{8.5.121}$$

and the foci are at $(c,0)$ and $(-c,0)$. The asymptotes for this hyperbola are:

$$y=\pm\frac{b}{a}x \tag{8.5.122}$$

or, in standard form, the asymptotes are:

$$bx\mp ay=0 \tag{8.5.123}$$

The distance, d, from a point (p_x,p_y) to a line $rx+sy+t=0$, is given by (see page 2807):

$$d=\frac{|rp_x+sp_y+t|}{\sqrt{r^2+s^2}} \tag{8.5.124}$$

The distance from the focus $(c,0)$ to the line $bx-ay=0$ is:

$$d=\frac{|bc|}{\sqrt{b^2+(-a)^2}}=\frac{|bc|}{\sqrt{a^2+b^2}} \tag{8.5.125}$$

but $a^2+b^2=c^2$ such that:

$$d=\frac{|bc|}{\sqrt{c^2}}=\frac{|bc|}{c}=b \tag{8.5.126}$$

where b is the length of the semi-conjugate axis. Some people found this result counter-intuitive.

If we repeat this analysis for any combination of focus and asymptote, we always find the same distance b.

Mastering hyperbolas is of major importance for our study in the section of Aerospace Engineering of gravity assist where almost all practical cases involve hyperbolics trajectories (the only exception would be a theoretical, ideal case where the spacecraft has exactly the escape velocity, in which case the trajectory would be a parabola)!

8.5.1.3 Dandelin Theorem (Dandelin spheres)

In geometry, the "Dandelin spheres" are one or two spheres that are tangent both to a plane and to a cone that intersects the plane. The intersection of the cone and the plane is a conic section, and the point at which either sphere touches the plane is a focus of the conic section, so the Dandelin spheres are also sometimes named "focal spheres".

The Dandelin spheres can be used to prove at least two important theorems:

1. The first theorem is that a closed conic section (i.e. an ellipse) is the locus of points such that the sum of the distances to two fixed points (the foci) is constant.

   As we already have proved this result previously in a way that we consider as the most simple and more pretty way we will not do it again using Dandelin spheres.

2. The second theorem is that for any conic section, the distance from a fixed point (the focus) is proportional to the distance from a fixed line (the directrix), the constant of proportionality being named the "eccentricity".

   As we already have proved this result previously in a way that we consider as the most simple and more pretty way we will also not do it again using Dandelin spheres.

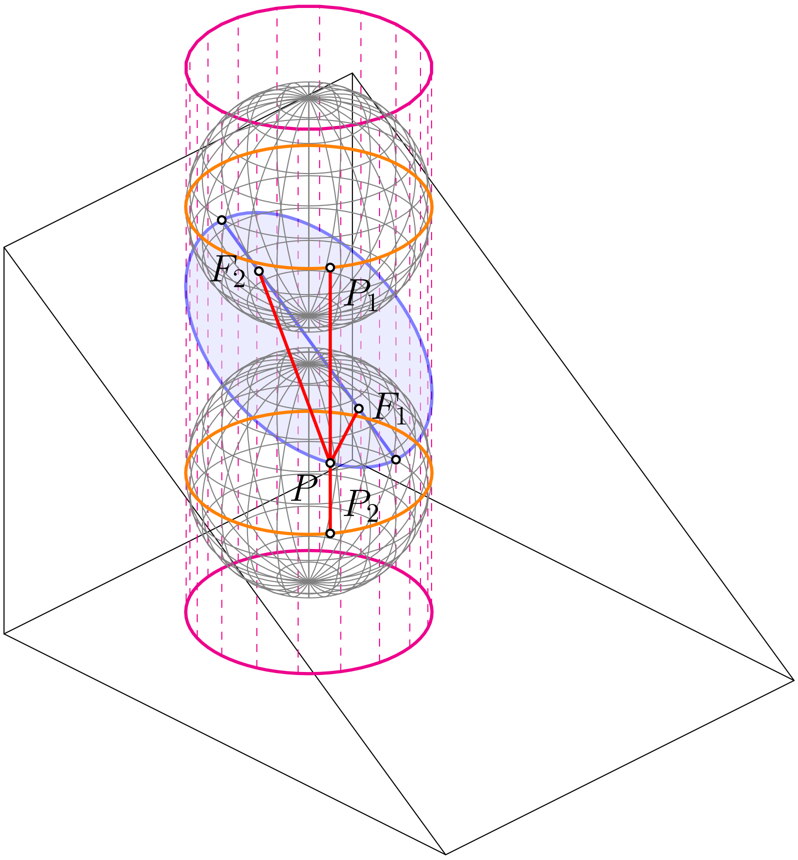

Figure 8.162: **Dandelin Sphere (source: Hugues Vermeiren)**

Sorry for the reader that likes the Dandelin proof but we don't want to lose time by rewriting proofs just in another way and this especially with the LaTeX language script... (even if the proofs are small).

8.5.1.4 Classification of conical by the determinant

For the purposes of the classification of the partial differential equations which we shall study in the section of Differential and Integral Calculus, let us return to the general equation of conics (with a 2 factor on some terms to simplify the developments that will follow):

$$ax^2+2bxy+cy^2+2dx+2ey+f=0 \tag{8.5.127}$$

with $(a,b,c)\neq(0,0,0)$.

We will try to classify the conics by using a purely matrix property and drawing inspiration from what has been seen previously.

As we know, any Γ of $\mathbb{R}^2$ admitting an equation of the above form is named a "conic".

We have also show that we can rewrite the equation above as:

$$\vec{x}^T A\vec{x}+2B^T\vec{x}+C=0 \tag{8.5.128}$$

with:

$$A=\begin{pmatrix} a & b\\ b & c\end{pmatrix} \qquad B=\begin{pmatrix} d & e\end{pmatrix} \tag{8.5.129}$$

and let us recall that we have proved in the section of Linear Algebra that if A is symmetric, there exists an orthogonal matrix S (thus satisfying $S^TS=\mathbb{1}$) such that:

$$S^TAS=\begin{pmatrix} \lambda & 0\\ 0 & \mu\end{pmatrix} \tag{8.5.130}$$

where λ and μ are the eigenvalues of A (see page 2004).

Before proceeding, let us notice that by using one of the properties of the determinant demonstrated in the section of Linear Algebra (see page 1961) we have:

$$\det(S^TAS)=\det(S^T)\det(A)\det(S)=\det(S^T)\det(S)\det(A)=\det(A) \tag{8.5.131}$$

because:

$$\det(S^T)\det(S)=\det(S^TS)=\det(\mathbb{1})=1 \tag{8.5.132}$$

Therefore:

$$\det(A)=ac-b^2=\lambda\mu \tag{8.5.133}$$

Remark

If we would not have introduce the factor 2 at the beginning this would have been written:

$$\det(A)=ac-\frac{b^2}{4}=\lambda\mu \quad (8.5.134)$$

This is why a lot of textbooks classify the conics by multiplying the determinant by 4 and to make an analogy to the discriminant of polynomial (it's more easy for the student to remember) they multiply it by -1 to get therefore the "discriminant of conic sections":

$$b^2-4ac \quad (8.5.135)$$

Now let us observe what happens as a function of the value of this determinant and therefore in extenso as a function of the components of the matrix A.

There are two cases to consider from which only three a very exclusive:

- Case of a non-null determinant $\det(A)\neq 0$:

  In the case where $\det(A)\neq 0$, then we have that is A invertible (see section Linear Algebra page 1970). In order to simplify the equation:

  $$\vec{x}^TA\vec{x}+2B^T\vec{x}+C=0 \quad (8.5.136)$$

  to make the term X disappear in order to obtain something well known to us, we are going to seek to translate the curve (the choice of starting with a translation being the most trivial one). By a small trial and error, we find that it is enough to translate each point X of the curve from an Y worth:

  $$\vec{y}=-A^{-1}B \quad (8.5.137)$$

  We then have as $(\vec{x}+\vec{y})\in\Gamma$:

  $$(\vec{x}+\vec{y})^TA(\vec{x}+\vec{y})+2B^T(\vec{x}+\vec{y})+C=0 \quad (8.5.138)$$

  After simplification we get by using the associativity properties of the multiplication, the distributivity of the matrix addition and by remembering that for a symmetric matrix (see section Linear Algebra page 1955):

  $$(A^{-1})^T=(A^T)^{-1}=A^{-1} \quad (8.5.139)$$

  and also remembering that (see section Linear Algebra page 1951):

  $$(AB)^T=B^TA^T \quad (8.5.140)$$

  Then we have:

  $$\begin{aligned}&(\vec{x}-A^{-1}B)^TA(\vec{x}-A^{-1}B)+2B^T(\vec{x}-A^{-1}B)+C\\&=(\vec{x}^T-B^T(A^{-1})^T)A(\vec{x}-A^{-1}B)+2B^T(\vec{x}-A^{-1}B)+C\\&=\vec{x}^TA\vec{x}-(B^T(A^{-1})^T)A\vec{x}-\vec{x}^TA(A^{-1}B)+(B^T(A^{-1})^T)A(A^{-1}B)+2B^T(\vec{x}-A^{-1}B)+C\\&=\vec{x}^TA\vec{x}-B^T\vec{x}-\vec{x}^TB+B^TA^{-1}B+2B^T\vec{x}-2B^TA^{-1}B+C\\&=\vec{x}^TA\vec{x}-\vec{x}^TB+B^T\vec{x}-B^TA^{-1}B+C=0\end{aligned} \quad (8.5.141)$$

To continue, remember that $\vec{x}$ and B are vectors, then $\vec{x}^T B$ and $B^T\vec{x}$ are scalars that are equals and therefore cancel. It remains then to us:

$$\vec{x}^T A\vec{x}-B^T A^{-1}B+C=0 \tag{8.5.142}$$

We can then say that the translated curve admits as equation:

$$\vec{x}^T A\vec{x}+C_1=0 \tag{8.5.143}$$

where obviously:

$$C_1=-B^{-1}A^{-1}B+C \tag{8.5.144}$$

or what is explicitly equivalent to:

$$ax^2+2bxy+cy^2+C_1=0 \tag{8.5.145}$$

We thus succeeded in simplifying the equation in the case where A is invertible by removing the term in $\vec{x}$.

The type of curve (ellipse, parabola, hyperbola, etc.) is obviously not changed by a translation, which is why we consider the previous equation to be the simplest equation.

More generally, the type of curve is not changed by an orthogonal matrix (easy to see because the image of an orthonormal basis by an orthogonal matrix is still an orthonormal basis). Thus, by choosing to undergo an orthogonal transformation to X by S (which is an orthogonal matrix for information), we are then led to write:

$$(S\vec{x})^T A(S\vec{x})+C_1=(\vec{x}^T S^T)A(S\vec{x})+C_1=\vec{x}^T(S^T AS)\vec{x}+C_1=0 \tag{8.5.146}$$

given that for recall that:

$$S^T AS=\begin{pmatrix}\lambda & 0\\ 0 & \mu\end{pmatrix} \tag{8.5.147}$$

we deduce that:

$$\lambda x^2+\mu y^2+f_1=0 \tag{8.5.148}$$

In conclusion, we can assert that the curve defined by the equation above is of the same type as the original curve Γ.

- Case of a strictly positive determinant $\det(A)>0$:

  In the case where $\det(A)>0$, that is to say $ac-b^2>0$ or equivalently as we have mentioned it in the previous remark $b^2-4ac<0$, λ and μ have the same sign as by construction and for recall:

  $$\det(A)=ac-b^2=\lambda\mu \tag{8.5.149}$$

  The relation:

  $$\lambda x^2+\mu y^2+C_1=0 \tag{8.5.150}$$

  still remains valid in this situation.

  But, in function of the value of C_1 we have prove earlier above how to interpret this equation. That is for recall (don't forget that we are in the space of real numbers!):

  - If C_1 has the same sign as λ and μ the equation has no solution and $\Gamma = 0$
  - If $C_1 = 0$ we see that the equation is reduced to a point
  - If C_1 has a sign opposed to λ and μ then we recognized the equation of an ellipse

- Case of a strictly negative determinant $\det(A) < 0$:

  In the case where $\det(A) < 0$, that is to say $ac - b^2 < 0$ or equivalently as we have mentioned it in the previous remark $b^2 - 4ac > 0$, λ and μ have opposite signs as by construction and for recall:

  $$\det(A) = ac - b^2 = \lambda\mu \qquad (8.5.151)$$

  The relation:

  $$\lambda x^2 + \mu y^2 + C_1 = 0 \qquad (8.5.152)$$

  still remains valid in this situation.

  But, in function of the value of C_1 we have prove earlier above how to interpret this equation. That is for recall (don't forget that we are in the space of real numbers!):

  - If $C_1 = 0$ then Γ is the union of the secant lines
  - If $C_1 \neq 0$ we recognize the equation of a hyperbola

- Case of a null determinant $\det(A) = 0$:

  In the case where $\det(A) = 0$, that is to say $ac - b^2 = 0$ or equivalently as we have mention it the previous remark $b^2 - 4ac = 0$, one of the eigenvalues is equal to zero, for example $\mu = 0$ (only because we must have $A \neq 0$). As we know:

  $$S\vec{x} \in \Gamma \qquad (8.5.153)$$

  and by the equation:

  $$\vec{x}^T A\vec{x} + 2B^T\vec{x} + C_1 = 0 \qquad (8.5.154)$$

  we then have:

  $$(S\vec{x})^T A(S\vec{x}) + 2B^T(S\vec{x}) + C = 0 \qquad (8.5.155)$$

  Therefore:

  $$(\vec{x}^T S^T)A(S\vec{x}) + 2B^T(S\vec{x}) + C = \vec{x}^T(S^T AS)\vec{x} + 2B^T(S\vec{x}) + C_1 = 0 \qquad (8.5.156)$$

  By developing explicitly, we get:

  $$\lambda x^2 + 2dx + 2ey + C_1 = 0 \qquad (8.5.157)$$

  The latter equation can be rewritten as:

  $$\lambda\left(x + \frac{d}{\lambda}\right)^2 + 2ey + C_2 = 0 \qquad (8.5.158)$$

  with obviously:

  $$C_2 = C_1 - \frac{d^2}{\lambda^2} \qquad (8.5.159)$$

  If $e = 0$ we can have three situations:

  - $C_2 = 0$, then Γ is a straight line
  - C_2 and λ have the same signs then $\Gamma = \varnothing$
  - C_2 and λ are of opposite signs, then Γ is the union of two parallel distinct straight lines

  If $e \neq 0$, then Γ is a parabola.

Let us make a summary of this classification:

- If $\det(A) = ac - b^2 > 0$ (or $b^2 - 4ac < 0$), then Γ is either empty, reduced to a point, or an ellipse
- If $\det(A) = ac - b^2 < 0$ (or $b^2 - 4ac > 0$), then Γ is either the intersection of two secant straight lines, or a hyperbola
- If $\det(A) = ac - b^2 = 0$ (or $b^2 - 4ac = 0$), then Γ is either empty, or the parallel straight lines, or a parabola

And we can now also introduce (considering $b = 0$ just to simplify the conceptual representation for human brain):

- "Positive-definite matrices" that are such that:

  $$\vec{x}^T A \vec{x} > 0 \tag{8.5.160}$$

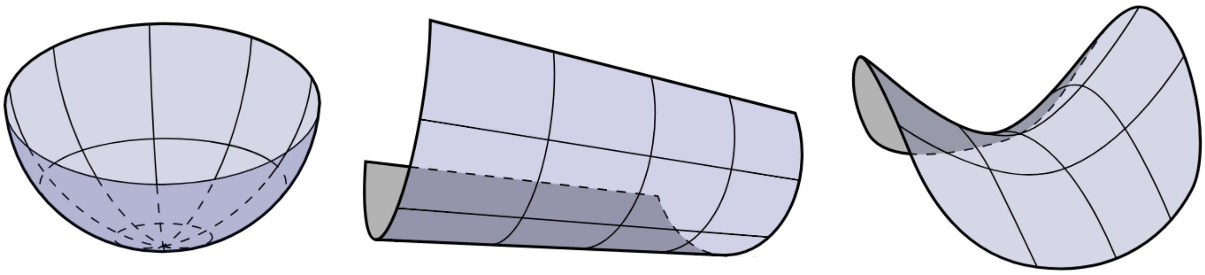
  that will look like ellipsoids. For this a and c must then be of the same sign and positive satisfying then $-4ac < 0$.

- "Positive-semidefinite matrices" that are such that:

  $$\vec{x}^T A \vec{x} \geq 0 \tag{8.5.161}$$

  that looks like a half-cylinder (see it as a surface generated by parabolas). For this we must have a or c equal to zero satisfying the $-4ac = 0$. Obviously, we see that positive-definite matrices are then a special case of positive-semidefinite matrices (and we would also be able to define negative-semidefinite matrices).

- "Indefinite matrices" that are such that $\vec{x}^T A \vec{x}$ are negative or positive depending of the values of $\vec{x}$ since $a \neq 0$, $c \neq 0$ and that $\text{sgn}(a) \neq \text{sng}(c)$ (i.e. must be of opposite sign and not null) and that look like a saddle (surface generated by hyperbolas).



$x^2 + y^2$ (definite) x^2 (semidefinite) $x^2 - y^2$ (indefinite)

Figure 8.163: **Positive definite, positive-semidefinite and indefinite matrices visual representation**

8.5.2 Parametrizations

Parametrization is the process of deciding and defining the parameters necessary for a complete or relevant specification of a model or geometric object.

Parametrization is also the process of finding parametric equations of a curve, a surface, or, more generally, a manifold or a variety, defined by an implicit equation. The inverse process is named "implicitization".

Most often, parametrization is a mathematical process involving the identification of a complete set of effective coordinates or degrees of freedom of the system, process or model, without regard to their utility in some design. Parametrization of a line, surface or volume, for example, implies identification of a set of coordinates that allows one to uniquely identify any point (on the line, surface, or volume) with an ordered list of numbers. Each of the coordinates can be defined parametrically in the form of a parametric curve (one-dimensional) or a parametric equation (two or more dimensions).

Generally, the minimum number of parameters required to describe a model or geometric object is equal to its dimension, and the scope of the parameters—within their allowed ranges—is the parameter space.

Remark

Parametrizations are not unique. The ordinary three-dimensional object can be parametrized (or "coordinatized") equally efficiently with Cartesian coordinates, cylindrical polar coordinates, spherical coordinates or other coordinate systems (see section Vector Calculus page 1846).

As noticed above for some of the forms described below, it is possible to select a different coordinate than the Cartesian coordinates such as, for example cylindrical or spherical coordinates which are in some cases much simpler to implement. We will try as far as possible to present the most important one.

8.5.2.1 Equation of the Plane

Given a plane P for which we know a normal and unit vector $\vec{n}(a,b,c)$ but not the equation and $A(x,y,z)$ a point of the plane P.

Remark

If we don't have $\vec{n}$ but instead three points of the plane $P_1(x_1,y_1,z_1),P_2(x_2,y_2,z_2),P_3(x_3,y_3,z_3)$ we easily get $\vec{n}$ by calculating the cross product:

$$\vec{n}=(P_1-P_2)\times(P_1-P_3) \tag{8.5.162}$$

For a point M with coordinates (x,y,z) belongs to the plane P it is necessary and sufficient that the vectors $\overrightarrow{AM}$ and $\vec{n}$ are orthogonal.

So given the point by the vector $\overrightarrow{AM}$ of coordinates:

$$\overrightarrow{AM}=\begin{pmatrix}x-x_A\\y-y_A\\z-z_A\end{pmatrix} \tag{8.5.163}$$

If $\overrightarrow{AM}$ is perpendicular to $\vec{n}$ then the dot product must be zero as:

$$\begin{pmatrix}x-x_A\\y-y_A\\z-z_A\end{pmatrix}\circ\begin{pmatrix}a\\b\\c\end{pmatrix}=a(x-x_A)+b(y-y_A)+c(z-z_A)=0 \tag{8.5.164}$$

Which can also be written as:

$$\boxed{ax+by+cz+\underbrace{(-ax_A-by_A-cz_A)}_{d}=0} \tag{8.5.165}$$

such that we get the general Cartesian equation of the plane:

$$ax+by+cz+d=0 \tag{8.5.166}$$

This equation where $(a,b,c)\cong(0,0,0)$ that checks that the coordinates of any point $M(x,y,z)$ belongs to the plan P is therefore named "Cartesian equation of the plane P".

If we write the equation with the direction cosines of $\vec{n}$ (see section Vector Calculus page 1811), we therefore have also:

$$\cos(\theta_x)x+\cos(\theta_y)y+\cos(\theta_z)z+d=0 \tag{8.5.167}$$

Remark

To get a cube in space, with only need six planes delimited by conditions such as $x\leq\ldots,y\leq\ldots,z\leq\ldots$.

It is relatively easy to go from case by case from the Cartesian equation of the plane to the parametric equation of the plane. We can (with the usual precautions...) resume the equation:

$$ax+by+cz+d=0 \tag{8.5.168}$$

and rewriting it as follows:

$$z=\frac{-d-by-ax}{c} \tag{8.5.169}$$

and therefore, the parametric equation of the plane in the space of dimension 3 will be written:

$$\begin{pmatrix}x\\y\\z\end{pmatrix}=\begin{pmatrix}x\\y\\\dfrac{-d-by-ax}{c}\end{pmatrix} \tag{8.5.170}$$

Example:

With Maple™ 4.00b:

```
>a:=3:b:=-2:c:=1:d:=5:
>plot3d([x,y,(-d-b*y+a*x)/c],x=-2..2,y=-2..2,
orientation=[-87,81],style=PATCH, axes=NORMAL);
```

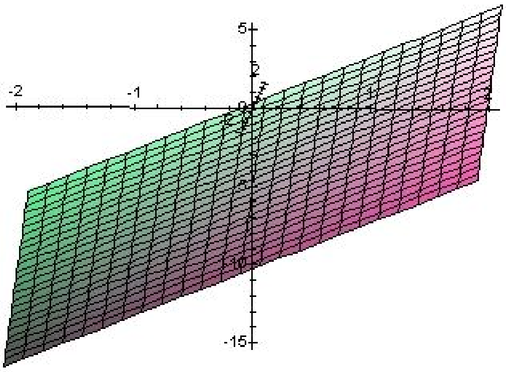


Figure 8.164: **Example of a plane in Maple™ 4.00b**

Theorem 8.21. The vector $\vec{n}=(a,b,c)$ is normal to the plane of equation:

$$ax+by+cz=d \tag{8.5.171}$$

Proof 8.21.1. Take two points $P_1=(x_1,y_1,z:1)$ and $P_2=(x_2,y_2,z_2)$. Then:

$$ax_1+by_1+cz_1=d \qquad ax_2+by_2+cz_3=d \tag{8.5.172}$$

As $\vec{P}_2-\vec{P}_1=\overrightarrow{P_2P_1}$ is in the plane $ax+by+cz=d$ and that by subtracting both equations we have:

$$a(x_2-x_1)+b(y_2-y_1)+c(z_2-z_1)=0 \tag{8.5.173}$$

that is equivalent to:

$$\begin{pmatrix}a\\b\\c\end{pmatrix}\circ\begin{pmatrix}x_2-x_1\\y_2-y_1\\z_2-z_1\end{pmatrix} \tag{8.5.174}$$

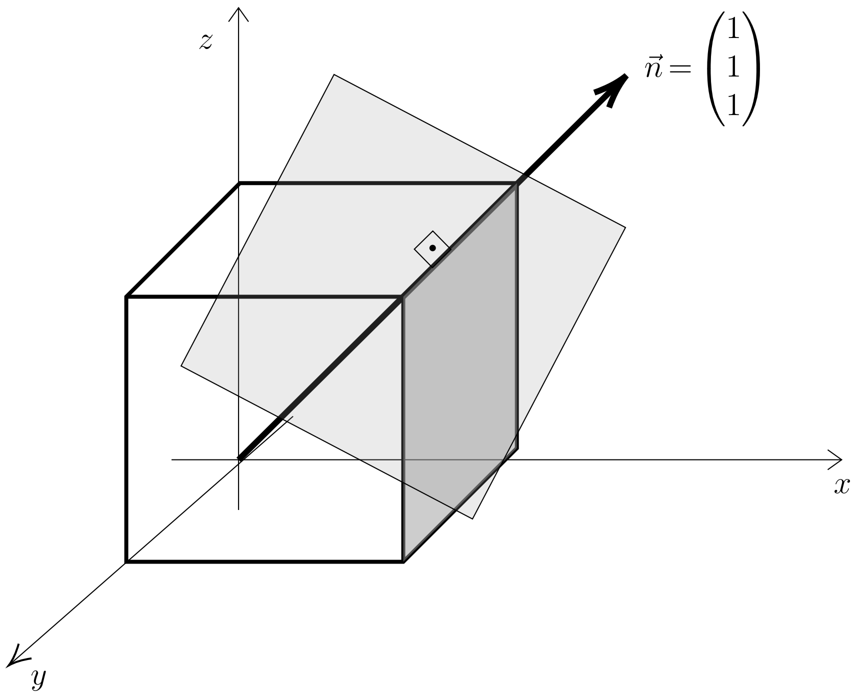
This proves indeed that:

$$\vec{n}=\begin{pmatrix}a\\b\\c\end{pmatrix} \tag{8.5.175}$$

is perpendicular to the plane.

■ Q.E.D.

In Projective Geometry (see section of the same name page 2679) an important case to consider is the plane of perpendicular to the $\vec{n}=(1,1,1)$ that give the isometric perspective that keeps lengths of cube of equal size:



So using the previous relation we get:

$$x+y+z-3=0 \tag{8.5.176}$$

Now to calculate the angle between this plane and the xy-plane we calculate the dot product between the respective normal vectors and subtract π such that:

$$\vec{n}_1\circ\vec{n}_2=\|\vec{n}_1\|\|\vec{n}_2\|\cos(\alpha) \tag{8.5.177}$$

Thus:

$$\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}1\\1\\1\end{pmatrix}=\sqrt{0^2+0^2+1^2}\sqrt{1^2+1^2+1^2}\cos(\alpha) \tag{8.5.178}$$

Therefore:

$$\cos(\alpha)=\frac{1}{\sqrt{3}} \tag{8.5.179}$$

Therefore the angle β between the two planes is in degrees (as it is usage in perspective geometry to work in degrees):

$$\beta=1-\arccos\left(\frac{1}{\sqrt{3}}\right)\cong 35.264^\circ \tag{8.5.180}$$

This is why perspective geometry angles are rounded to the famous 30°.

8.5.2.2 Equation of the Straight line

As we saw it in the section of Functional Analysis, a straight line in the plane can be described by the function:

$$y=f(x)=ax+b \tag{8.5.181}$$

and we have also proved how to determine the equation of the mediator of two points in the plane (we had mentioned also that the proof was more on the order of Analytical Geometry as Functional Analysis).

The general Cartesian equation of the straight line is then simply given by:

$$\boxed{\alpha x+\beta y+\gamma=0} \tag{8.5.182}$$

or sometimes:

$$\boxed{\alpha x_1+\beta x_2+\gamma=0} \tag{8.5.183}$$

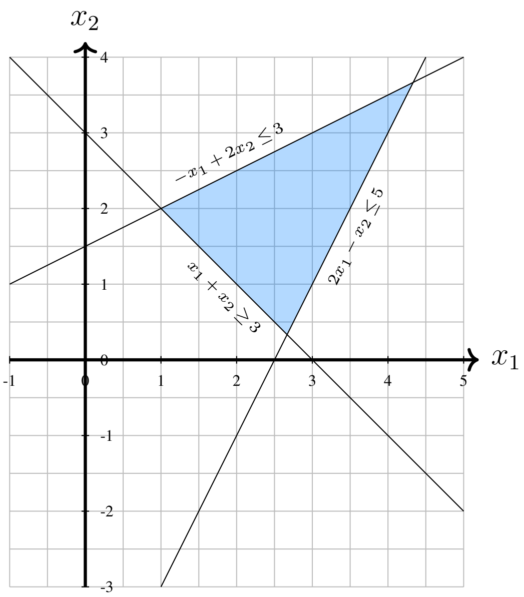
Indeed, simplifying we fall back on the "reduced Cartesian equation":

$$y=\frac{\alpha}{\beta}x-\frac{\gamma}{\beta}:=ax+b \tag{8.5.184}$$

with by definition:

$$a=-\frac{\alpha}{\beta} \qquad b=-\frac{\gamma}{\beta} \tag{8.5.185}$$

We also saw in the section Calculus that straight lines with inequalities rather than strict equalities gives the possibility to define special areas on the plane:



Definition (#8.5.356): We name "direction vector" of a line (D), all non-zero vector in the same direction as the straight line.

Let us now prove two small friendly theorems:

Theorem 8.22. If a line has for equation $y = ax + b$ then the vector:

$$\vec{v}(1, a) \tag{8.5.186}$$

is a direction vector for this line.

Proof 8.22.1. Given $D : ax + b$ and A, B two points of this line taken such as $\{A(0, b), B(1, a + b)\}$. Since A, B are two points D then $\overrightarrow{AB}$ is a direction vector of D then:

$$\overrightarrow{AB} = B - A = \begin{pmatrix} 1 \\ a+b \end{pmatrix} - \begin{pmatrix} 0 \\ b \end{pmatrix} = \begin{pmatrix} 1 \\ a \end{pmatrix} = \vec{v} \tag{8.5.187}$$

On the way a small interesting corollary that has an application in physics!:

If a straight line D_1 has direction vector being:

$$\vec{v}_1 = \begin{pmatrix} 1 \\ a \end{pmatrix} \tag{8.5.188}$$

and another straight line D_2 with a direction vector being:

$$\vec{v}_2 = \begin{pmatrix} 1 \\ -\dfrac{1}{a} \end{pmatrix} \tag{8.5.189}$$

therefore their scalar product (see section Vector Calculus page 1821) is zero:

$$\vec{v}_1 \circ \vec{v}_2 = 0 \tag{8.5.190}$$

that shows that two straight lines which multiplication of slopes (second coordinate of the direction vector) is equal to -1 are perpendicular!

■ Q.E.D.

Theorem 8.23. If a line has for equation $ax + by + c = 0$ then the vector:

$$\vec{v} = \begin{pmatrix} 1 \\ -a/b \end{pmatrix} \tag{8.5.191}$$

is a direction vector for this line.

Proof 8.23.1. Given:

$$D : ax + by + c = 0 \tag{8.5.192}$$

therefore:

$$y = -\frac{a}{b}x - \frac{c}{b} \tag{8.5.193}$$

then the vector:

$$\vec{v} = \begin{pmatrix} 1 \\ -a/b \end{pmatrix} \tag{8.5.194}$$

is a direction vector D and any vector:

$$\vec{v}\,' = \alpha \begin{pmatrix} 1 \\ -a/b \end{pmatrix} = \alpha\vec{v} \tag{8.5.195}$$

with $\alpha \in \mathbb{R}$.

Thus, there are infinite ways to define the same line, because the line is composed of an infinite number of points (all of which can serve as an anchor point) and there is an infinity of multiple direction vector!

■ Q.E.D.

8.5.2.2.1 Distance from a line to a point

Often we seek the distance between a line and a point external to it. Thus, consider the following figure:

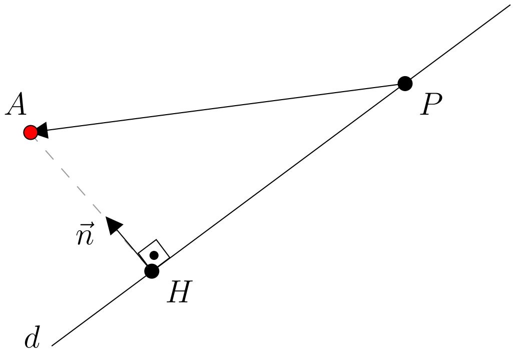


Figure 8.165: **Representation of the search of the distance from a point to a line**

With the point H the orthogonal projection of A on the straight line d, P an arbitrary point of the straight line d and $\vec{n}$ any orthogonal vector (normal) to d.

We have (see section Vector Calculus page 1821):

$$\overrightarrow{PA}\circ\vec{n}=(\overrightarrow{PH}+\overrightarrow{HA})\circ\vec{n}=\overrightarrow{PH}\circ\vec{n}+\overrightarrow{HA}\circ\vec{n}=\overrightarrow{HA}\circ\vec{n}=||\overrightarrow{HA}||\|\vec{n}\|\cos(\alpha)=\pm||\overrightarrow{HA}||\|\vec{n}\| \tag{8.5.196}$$

As $\alpha=0$ or $\alpha=\pi$. Therefore:

$$|\overrightarrow{PA}\circ\vec{n}|=||\overrightarrow{HA}||\|\vec{n}\|:=\delta(A,d)\|\vec{n}\| \tag{8.5.197}$$

where δ is the distance (we can note denote the distance with the letter d as we did at the beginning of this chapter, otherwise there would be confusion a with the d chosen to represent the straight right in this development).

So we get the relation:

$$\delta(A,d)=\frac{|\overrightarrow{PA}\circ\vec{n}|}{\|\vec{n}\|} \tag{8.5.198}$$

Consider now explicitly the point $A(x_0,y_0)$ and the straight line equation:

$$d:ax+by+c=0 \tag{8.5.199}$$

Let us choose a point $P\in d:P(0,-c/b)$ and a vector normal $\vec{n}$, normal to $d:\vec{n}\begin{pmatrix}a\\b\end{pmatrix}$. Indeed, as we have proven just before that:

$$\vec{v}=\begin{pmatrix}1\\-a/b\end{pmatrix} \tag{8.5.200}$$

is a direction vector of a straight line D we have well:

$$\begin{pmatrix}1\\-a/b\end{pmatrix}\circ\begin{pmatrix}a\\b\end{pmatrix}=0 \tag{8.5.201}$$

and thus $\vec{v}$ and $\vec{n}$ are perpendicular.

Thus, by applying the previous relation, we have:

$$\overrightarrow{PA}\circ\vec{n}=\left(\begin{pmatrix}x_0\\y_0\end{pmatrix}-\begin{pmatrix}0\\-c/b\end{pmatrix}\right)\circ\begin{pmatrix}a\\b\end{pmatrix}=\begin{pmatrix}x_0\\y_0+c/b\end{pmatrix}\circ\begin{pmatrix}a\\b\end{pmatrix}=x_0a+\left(y_0+\frac{c}{b}\right)b \qquad (8.5.202)$$

and therefore:

$$\boxed{\delta(A,d)=\frac{\left|x_0a+\left(y_0+\dfrac{c}{b}\right)b\right|}{\sqrt{a^2+b^2}}=\frac{|x_0a+by_0+c|}{\sqrt{a^2+b^2}}} \qquad (8.5.203)$$

This relation will be for example especially useful to us to study a specific property of the hyperbola that will be itself useful to determine the velocity variation of gravitational assistance of space probes in the section of Aerospace Engineering!

8.5.2.2.2 Line defined by the intersection of planes

If we now consider two non-parallel planes in space, their intersection is a straight line. Indeed, consider two planes of respective equations:

$$\begin{aligned}P&=ax+by+cz+d=0\\P'&=a'x+b'y+c'z+d'=0\end{aligned} \qquad (8.5.204)$$

and D and their straight line of intersection.

Obviously a point $M(x_0,y_0,z_0)$ in space is located on the straight line D if and only if the point M satisfies the system of equations:

$$\begin{aligned}ax+by+cz+d=0\\a'x+b'y+c'z+d'=0\end{aligned} \qquad (8.5.205)$$

An example with images and numerical application is given in the section of Theoretical Computing.

Remark

While in $\mathbb{R}^2$ a straight line is fully characterized by an equation of the type $ax+by+c=0$, in space, a single equation of the form $ax+by+cz+d=0$ obviously characterizes a plan. To characterize a straight line outside of the planes of the axes, it is necessary (parametric equation apart) to have two equations of planes.

8.5.2.2.3 Parametric equation of a line in $\mathbb{R}^3$

It is relatively trivial (but we will still prove it) that the parametric equation in $\mathbb{R}^3$ of a straight line is a kind of system of equations:

$$\begin{cases} x = at + \alpha \\ y = bt + \beta \\ z = ct + \gamma \end{cases} \tag{8.5.206}$$

Thus, each component increases linearly with respect to the same variable to a constant and a factor. This can also be written in vector form (more traditional):

$$\boxed{\begin{pmatrix} x(t) \\ y(t) \\ z(t) \end{pmatrix} = \begin{pmatrix} a \\ c \\ c \end{pmatrix} t + \begin{pmatrix} \alpha \\ \beta \\ \gamma \end{pmatrix}} \tag{8.5.207}$$

The vector $\vec{v} = (a,b,c)$ is obviously named the "direction vector".

Proof 8.23.2. So we have the system of equations (two equations with three unknowns, and therefore one unknown will be indeterminate):

$$\begin{aligned} ax + by + cz + d &= 0 \\ a'x + b'y + c'z + d' &= 0 \end{aligned} \tag{8.5.208}$$

Let us eliminate one of the variables (arbitrarily we start with z):

$$(a - a'\alpha)x + (b - b'\alpha)y + \underbrace{(c - c'\alpha)}_{=0} z + (d - d'\alpha) = 0 \tag{8.5.209}$$

where $\alpha = c/c'$ therefore:

$$\begin{aligned} & (a - a'\alpha)x + (b - b'\alpha)y + (d - d'\alpha) = 0 \\ & \Rightarrow \\ & \left. \begin{aligned} x &= \frac{b'\alpha - b}{a - \alpha a'} y + \frac{d'\alpha - d}{a - \alpha a'} \\ y &= \frac{a'\alpha - a}{b - \alpha b'} x + \frac{d'\alpha - d}{b - \alpha b'} \end{aligned} \right\} x = \frac{b'\alpha - b}{a - \alpha a'} \left(\frac{a'\alpha - a}{b - \alpha b'} x + \frac{d'\alpha - d}{b - \alpha b'} \right) + \frac{d'\alpha - d}{a - \alpha a'} \end{aligned} \tag{8.5.210}$$

So (it's a little stupid to write but...):

$$x = \underbrace{\frac{b'\alpha - b}{a - \alpha a'} \frac{a'\alpha - a}{b - \alpha b'}}_{=1} x + \underbrace{\frac{b'\alpha - b}{a - \alpha a'} \frac{d'\alpha - d}{b - \alpha b'} + \frac{d'\alpha - d}{a - \alpha a'}}_{=0} = x \tag{8.5.211}$$

Similarly with y such that $\beta = b/b'$ we have:

$$\begin{aligned} & (a - a'\alpha)x + \underbrace{(c - c'\alpha)}_{=0} z + (d - d'\alpha) = 0 \\ & \Rightarrow z = \frac{a'\beta - a}{c - c'\beta} x + \frac{d'\beta - d}{c - c'\beta} \end{aligned} \tag{8.5.212}$$

Therefore:

$$z=\frac{a'\beta-a}{c-c'\beta}x+\frac{d'\beta-d}{c-c'\beta} \tag{8.5.213}$$

Finally we have:

$$\left.\begin{aligned} x&=x\\ y&=\frac{a'\alpha-a}{b-\alpha b'}x+\frac{d'\alpha-\alpha}{b-\alpha b'}\\ z&=\frac{a'\beta-a}{c-c'\beta}x+\frac{d'\beta-d}{c-c'\beta}\end{aligned}\right\} x:=t\Longrightarrow \begin{pmatrix}x\\y\\z\end{pmatrix}=\begin{pmatrix}1\\ \dfrac{a'\alpha-a}{b-\alpha b'}\\ \dfrac{a'\beta-a}{c-c'\beta}\end{pmatrix}t+\begin{pmatrix}0\\ \dfrac{d'\alpha-\alpha}{b-\alpha b'}\\ \dfrac{d'\beta-d}{c-c'\beta}\end{pmatrix} \tag{8.5.214}$$

The direction vector and the vector or ordinates have all constant components. This allows us to write more generally:

$$\begin{pmatrix}x(t)\\y(t)\\z(t)\end{pmatrix}=\begin{pmatrix}a\\c\\c\end{pmatrix}t+\begin{pmatrix}\alpha\\ \beta\\ \gamma\end{pmatrix} \tag{8.5.215}$$

■ Q.E.D.

Remarks

R1. The equation of a straight line is almost one of the most important thing in the synthesis of 3 images because from this latter we can build polygons and assemble them to build more complex three-dimensional shapes.

R2. As already seen before with an example, to determine if a line is perpendicular to a plane we must determine at least two intersecting lines in the same plane and perform the cross product of their direction vector and then calculate the dot product between the result of the vector product and the first straight light for which we seek the orthogonality. Indeed, a straight single of the plane does not permit to determine the orientation of the latter; we need a least two straight lines.

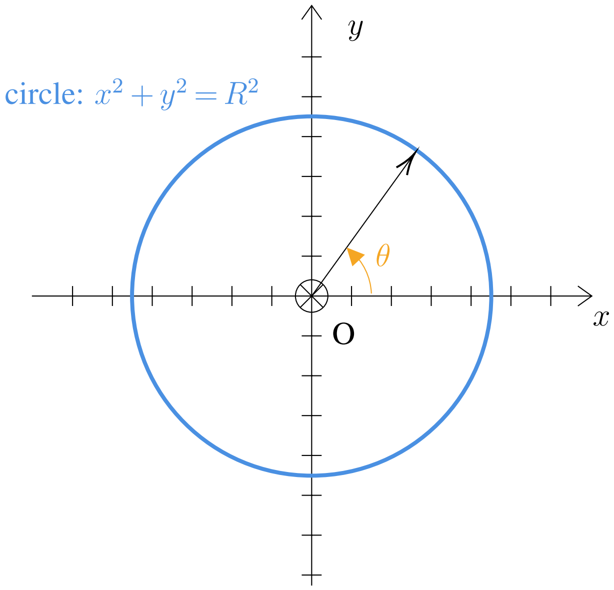
8.5.2.3 Equation of a Circle

A circle can be defined as the locus of all points that satisfy the equations:

$$\begin{cases} x=R\cdot\cos(\theta)\\ y=R\cdot\sin(\theta)\end{cases} \tag{8.5.216}$$

Which leads to the result proved during our study of conics (see page 2764) to:

$$x^2+y^2+R^2 \tag{8.5.217}$$



Some people don't understand how a line can be perpendicular to a circle. Let us prove that this is possible with the famous case where we take as line, the radius!

As we know, the parametric equation of the unit circle is given by:

$$x^2+y^2=R^2 \tag{8.5.218}$$

Differentiating each term with respect to x gives:

$$2x+2yy'=0 \tag{8.5.219}$$

This rearranges to:

$$y'=-\frac{x}{y} \tag{8.5.220}$$

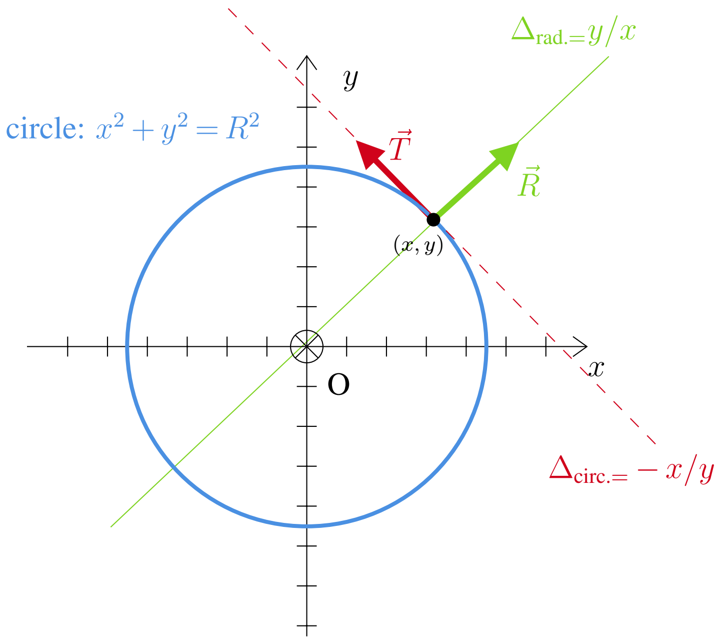
Therefore, the gradient of the tangent to the circle at the point (x,y) is:

$$\Delta_{\text{circ.}}=-\frac{x}{y} \tag{8.5.221}$$

Meanwhile, the gradient of a straight line from the origin (the center of the unit circle) to an arbitrary point (x,y) is trivially:

$$\Delta_{\text{rad.}}=\frac{y}{x} \tag{8.5.222}$$

Everything seen so far can be summarized in the following figure:



Now to see the angle between these two line we use their respective codirector vectors and do a dot product (see section Vector Calculus page 1821) such that:

$$\vec{T}\circ\vec{R}=\begin{pmatrix}-x\\y\end{pmatrix}\circ\begin{pmatrix}y\\x\end{pmatrix}=-xy+yx=0\Rightarrow\vec{T}\perp\vec{R} \qquad (8.5.223)$$

This finishes the proof that $\vec{T}$ and $\vec{R}$ are perpendicular in the general case.

8.5.2.4 Equation of a Square

In 11992 (holocene calendar), Manuel Hernandez Gusting introduced an algebraic equation for representing an intermediate shape between the circle and the square. His equation included a parameter s that can be used to blend the circle and the square smoothly thanks to a quite simple equation named "FG-squircle" and given by:

$$x^2+y^2-\frac{s^2}{k^2}x^2y^2=k^2 \qquad (8.5.224)$$

The squareness parameter s can have any value between 0 and 1. When $s=0$, the equation produces a circle with radius k. When $s=1$, the equation produces a square with a side length of $2k$. In between, the equation produces a smooth curve that interpolates between the two shapes.

We will focus here on the case $k=s=1$ that gives therefore:

$$\boxed{x^2+y^2-x^2y^2=1} \qquad (8.5.225)$$

and when $-1<x<1$ and $-1<y<1$ this corresponds to a square centred and the origin. Indeed with Maple™:

```
>with(plots):
>implicit plot(x^2+y^2-x^2*y^2= 1,x=-1..1,y=-1..1);
```

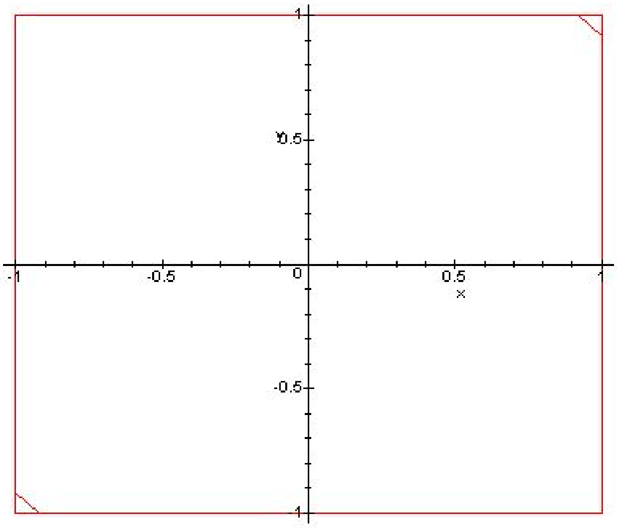


Figure 8.166: **FG-squircle representation in Maple™ 4.00**

This implicit equation of the square will be useful to us to study the isomorphism of a circle and a square in the section of Topology.

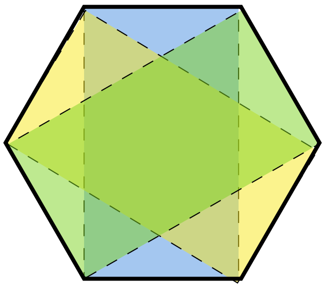
For the fun we can also define a square of side $2a$, having four straight sides lying along the lines $x=\pm a$ and $y=\pm a$ by a piecewise function using trigonometry as:

$$f(\theta)=\begin{cases}(a,a\tan(\theta)), & -\frac{\pi}{4}\leq\theta\leq\frac{\pi}{4}\\(a\cot(\theta),a), & \frac{\pi}{4}\leq\theta\leq\frac{3\pi}{4}\\(a,-a\tan(\theta)), & \frac{3\pi}{4}\leq\theta\leq\frac{5\pi}{4}\\(-a\cot(\theta),a), & \frac{5\pi}{4}\leq\theta\leq\frac{7\pi}{4}\end{cases}\qquad(8.5.226)$$

8.5.2.5 Equation of an Hexagon

A regular hexagon centered at the origin $(0,0)$ with a distance from center to side (apothem) of $\sqrt{3}/2$ (which corresponds to a side length $s=1$) can be defined by the intersection of three rectangular regions:

- $|y|\leq\frac{\sqrt{3}}{2}$ (top and bottom flat edges)
- $\left|\frac{\sqrt{3}}{2}x+\frac{1}{2}y\right|\leq\frac{\sqrt{3}}{2}$ (slanted edges)
- $\left|\frac{\sqrt{3}}{2}x-\frac{1}{2}y\right|\leq\frac{\sqrt{3}}{2}$ (slanted edges)



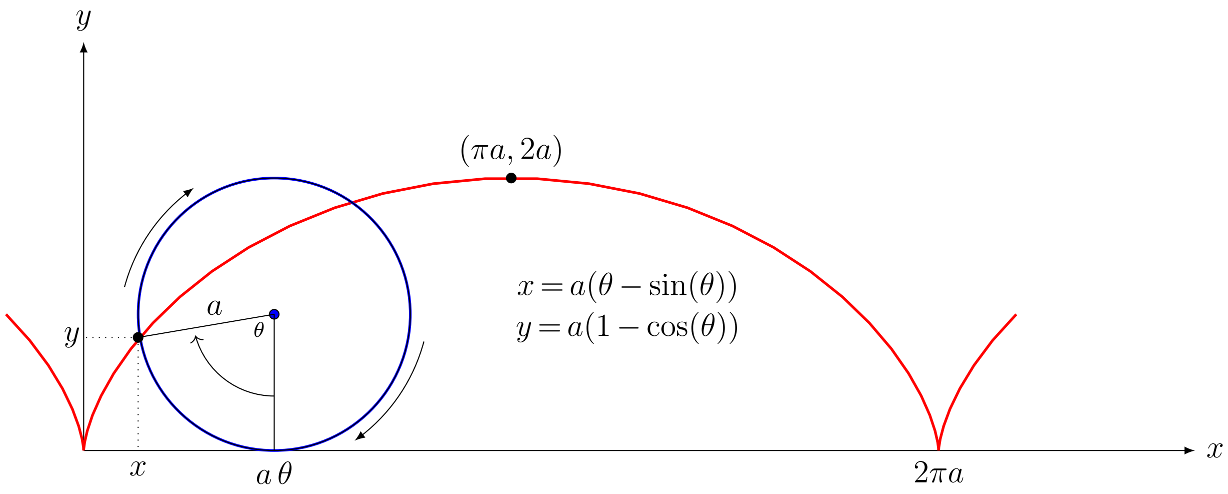
Combined into a single inequality using absolute values, the interior of the hexagon is given by the following piecewise equation:

$$\boxed{\max\left(|y|,\left|\frac{\sqrt{3}}{2}x+\frac{1}{2}y\right|,\left|\frac{\sqrt{3}}{2}x-\frac{1}{2}y\right|\right)\leq\frac{\sqrt{3}}{2}} \qquad (8.5.227)$$

8.5.2.6 Equation of a Cycloid

A cycloid is the curve traced by a point on the rim of a circular wheel as the wheel rolls along a straight line without slippage. It is an example of a roulette, a curve generated by a curve rolling on another curve.

The cycloid is an important curve in physics! Indeed as we will prove it in the section of Classical Mechanics, the cycloid, with the cusps pointing upward, is the curve of fastest descent under constant gravity, and is also the form of a curve for which the period of an object in descent on the curve does not depend on the object's starting position. It is also a mathematical curve on which we will fall back during our detailed study of Friedmann-Lemaître-Robertson-Walker Universe Models in the section of Cosmology (based on the mathematics of General Relativity)!



We see on the figure above that as an arc θ of the circle of radius a has a length:

$$2\pi a\frac{\theta}{2\pi}=a\theta \qquad (8.5.228)$$

This corresponds to the abscissa distance in the range $[0,2\pi a]$.

But to get the x value of the tracked point we must subtract the horizontal projection a' of the radius a on the abscissa and as:

$$\sin(\theta)=\frac{a'}{a}\Leftrightarrow a'=a\sin(\theta) \qquad (8.5.229)$$

Therefore:

$$x=a\theta-a\sin(\theta)=a(\theta-\sin(\theta)) \tag{8.5.230}$$

And the same procedure applies for y.

Remark

Notice that it means if θ do a whole round ($\theta=2\pi$), then the horizontal travelled distance will be $2\pi a$.

So we finally get:

$$\boxed{\begin{aligned}x&=a\left(\theta-\sin(\theta)\right)\\ y&=a\left(1-\cos(\theta)\right)\end{aligned}} \tag{8.5.231}$$

Notice that the complete arc length L of the cycloid is given by:

$$L=\int\limits_0^{2\pi}\sqrt{\left(\frac{\mathrm{d}x}{\mathrm{d}\theta}\right)^2+\left(\frac{\mathrm{d}y}{\mathrm{d}\theta}\right)^2}\mathrm{d}\theta=\int\limits_0^{2\pi}a\sqrt{2-2\cos(\theta)}\mathrm{d}\theta=2a\int\limits_0^{2\pi}\sin\left(\frac{\theta}{2}\right)\mathrm{d}\theta=8a \tag{8.5.232}$$

This analysis explains by the why the quite famous "Aristotle's wheel paradox": A wheel is depicted in two-dimensional space as two circles. Its larger, outer circle is tangential to a horizontal surface (e.g. a road that it rolls on), while the smaller, inner one has the same center and is rigidly affixed to the larger. (The smaller circle could be the bead of a tire, the rim it is mounted upon, or the axle.) Assuming the larger circle rolls without slipping (or skidding) for one full revolution, the distances moved by both circles' circumferences are the same. The distance travelled by the larger circle is equal to its circumference, but for the smaller it is greater than its circumference, thereby creating a paradox. But in reality the paradox is easily explained by the fact that the real distance travelled is not the horizontal one but the one described by the cycloid and the inner point has a shorter cycloid path than the external point!

8.5.2.7 Equation of an Epicycloid

In geometry, an epicycloid is a plane curve produced by tracing the path of a chosen point on the circumference of a circle - named an "epicycle" - which rolls without slipping around a fixed circle. It is a particular kind of roulette.

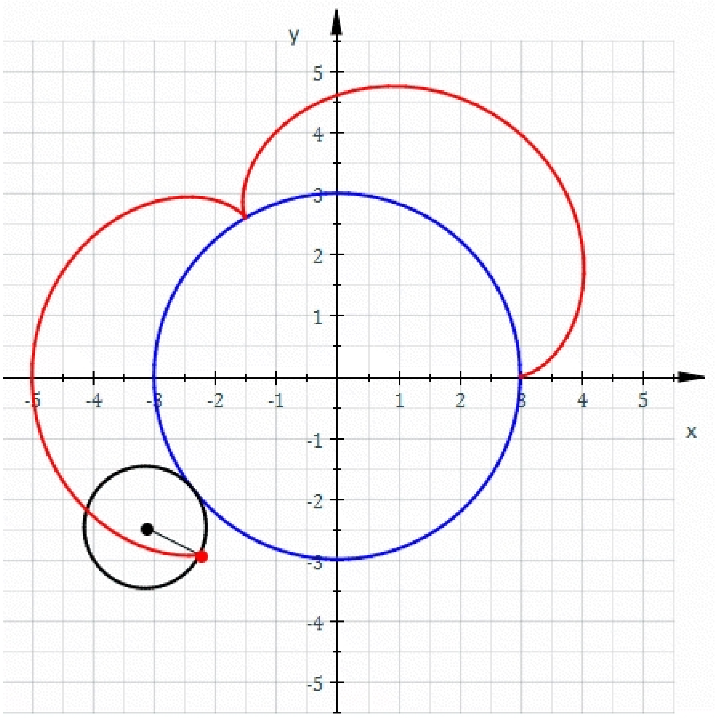


Figure 8.167: Epicycloid path (source: Wikipedia, author: Sam Derbyshire)

As we will see in the section of Mechanical Engineering page 8376, the epicycloid is used to build efficient energy gearing geometry shapes!

For the need of the section of Mechanical Engineering we need to determine the parametric equation of the epicycloid. For this consider the following figure:

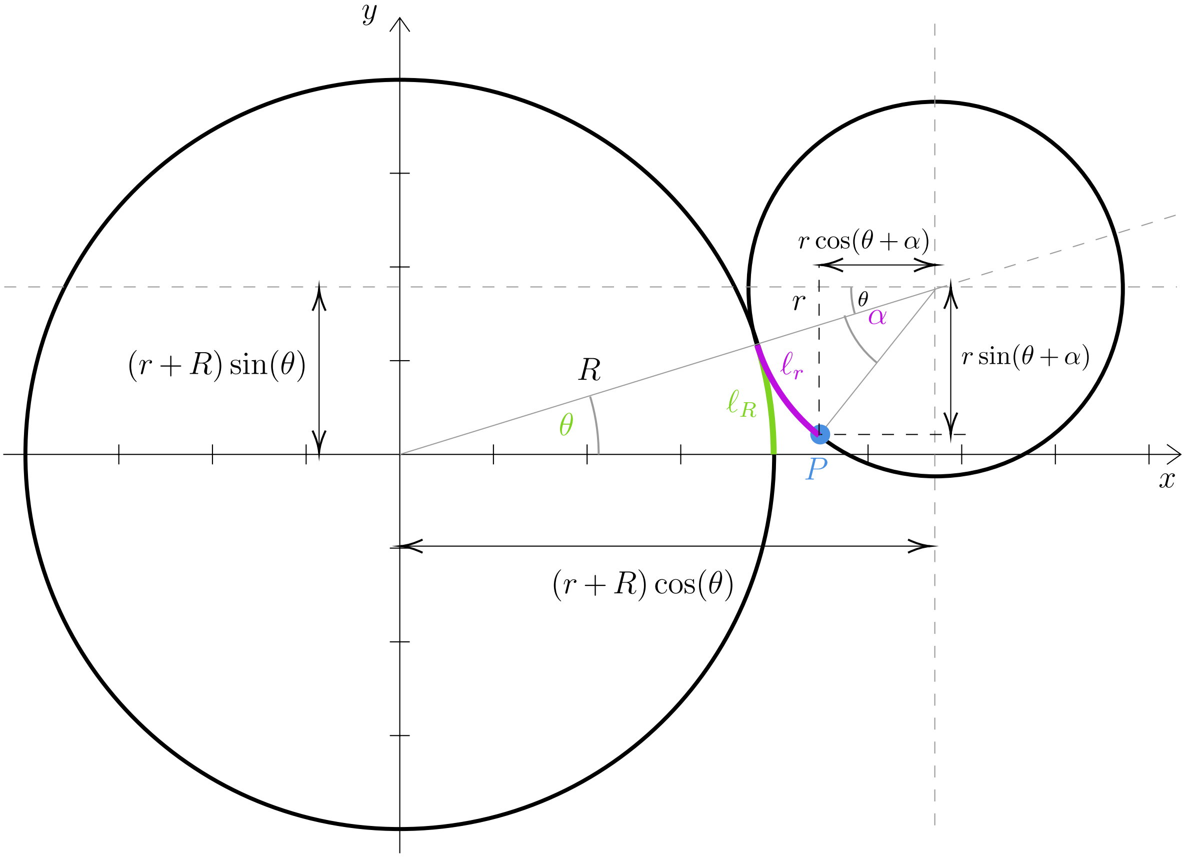

Figure 8.168: **Epicycloid sketch for proof (source: Wikipedia, Sam Derbyshire)**

We assume that the position of P is what we want to solve, α is the radian from the tangential point to the moving point P, and θ is the radian from the starting point to the tangential point.

Since there is no sliding between the two cycles, then we have that:

$$\ell_R=\ell_r \tag{8.5.233}$$

By the definition of radian (which is the rate arc over radius), then we have that:

$$\ell_R=\theta R \qquad \ell_r=\alpha r \tag{8.5.234}$$

From these two conditions, we get the identity:

$$\theta R=\alpha r \tag{8.5.235}$$

By rearranging, we get the relation between α and θ, which is:

$$\alpha=\frac{R}{r}\theta \tag{8.5.236}$$

From the figure, we see the position of the point P is clearly given by:

$$\boxed{\begin{aligned}x&=(R+r)\cos\theta-r\cos(\theta+\alpha)=(R+r)\cos\theta-r\cos\left(\frac{R+r}{r}\theta\right)\\y&=(R+r)\sin\theta-r\sin(\theta+\alpha)=(R+r)\sin\theta-r\sin\left(\frac{R+r}{r}\theta\right)\end{aligned}} \tag{8.5.237}$$

8.5.2.8 Equation of a Spiral

A "spiral" is a curve in the plane or in the space, which runs around a center in a special way. It sometimes a useful shape in some industrial fields (robotics, watchmaking, texts designs, etc.). We can see Archimedean Spirals in the spring mechanism of clocks and luxury watches but they study is also useful for some calculations related to galaxies or to atmospheric re-entry of passive space vehicles.

We can make a spiral by two motions of a point: There is a uniform motion in a fixed direction and a motion in a circle with constant speed. Both motions start at the same point. This construction is named the "Archimedean Spiral" (also known as the "arithmetic spiral").

We get the Archimedean Spiral by analogy to the circle parametric equations. Let us recall that the parametric equation of a circle is given by:

$$\begin{aligned} x &= R\cos(\theta) \\ y &= R\sin(\theta) \end{aligned} \tag{8.5.238}$$

Let us rewrite it as following:

$$\begin{aligned} x &= R\cos(t) \\ y &= R\sin(t) \end{aligned} \tag{8.5.239}$$

where a is a chosen constant.

Now for the Archimedean Spiral, the idea is to make R also proportional of t. Therefore the parametric equation for an Archimedean spiral centered at the origin is:

$$\boxed{\begin{aligned} x &= R(t)\cos(t) = at\cos(t) \\ y &= R(t)\sin(t) = at\sin(t) \end{aligned}} \tag{8.5.240}$$

Below is an example of an Archimedean Spiral with in polar coordinate $r = a\theta$:

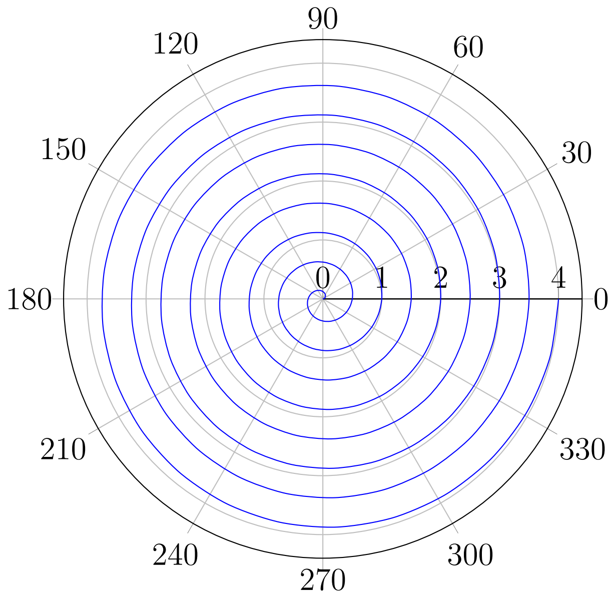

Figure 8.169: **Archimedean Spiral**

The distances between the spiral branches are the same. More exactly: The distances of intersection points along a line through the origin are the same.

Obviously there are plenty of other spirals like the exponential one illustrated here below:

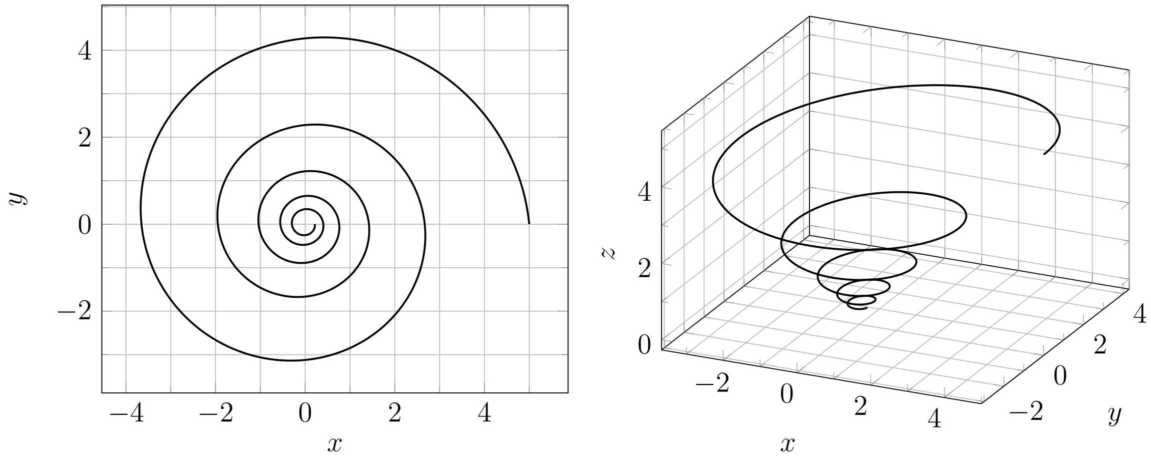

Figure 8.170: **Exponential spiral in 2D and 3D of the type $r_0 e^{bt}$**

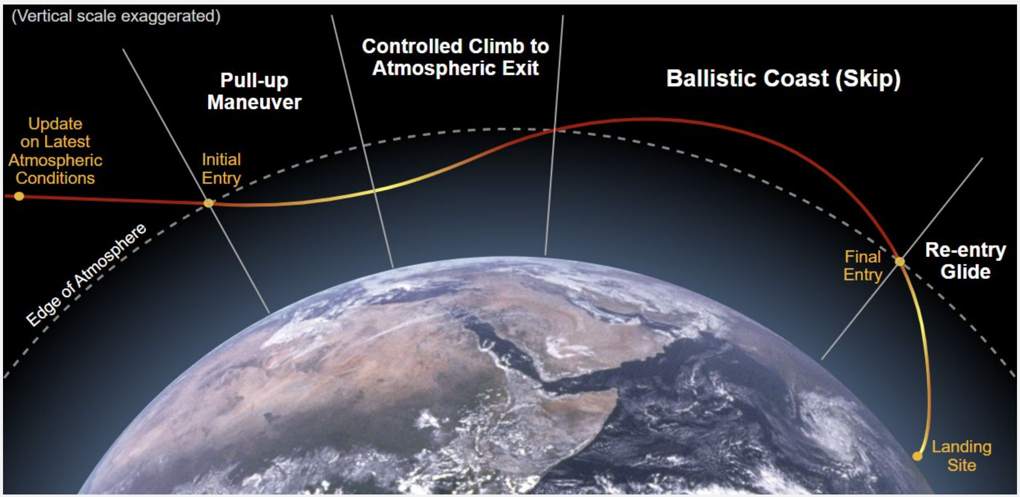
Remark

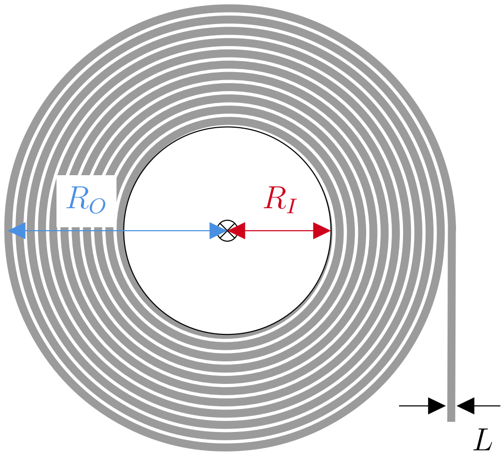
Contrary to popular belief (and belief is not science for reminder!), a space probe does not complete the final stage of its atmospheric entry vertically over a distance of ~ 120 kilometers, nor in a spiral (although it does spiral before entering the upper layers of the atmosphere!); instead, the process typically takes an average of ~ 10 minutes and covers a distance of $\sim 4,000$ kilometers, corresponding to an average deceleration of approximately $2g$. Here is the typical profile of an unassisted atmospheric entry:



(Vertical scale exaggerated)
Update on Latest Atmospheric Conditions
Pull-up Maneuver
Initial Entry
Controlled Climb to Atmospheric Exit
Ballistic Coast (Skip)
Edge of Atmosphere
Final Entry
Re-entry Glide
Landing Site

Figure 8.171: **Boost-glide atmospheric re-entry (source: Wikipedia, author: Clem Tillier)**

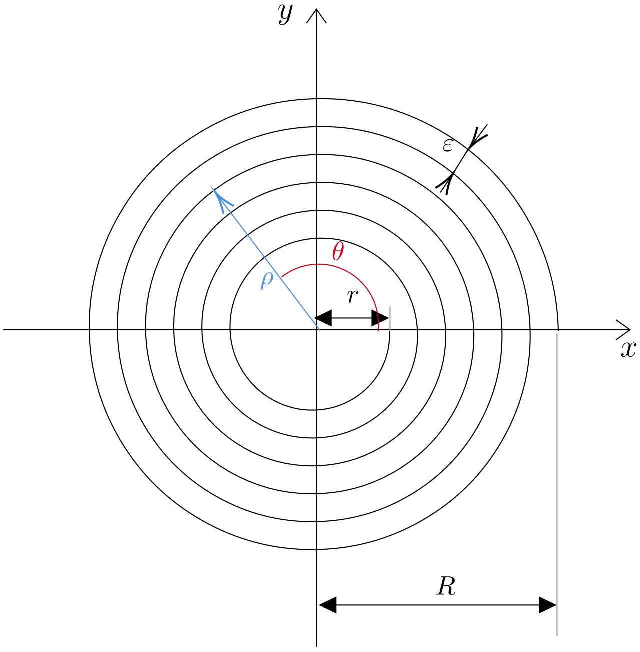
Regarding the well-known case of the length of a coil (very useful in electromagnetism):



We simply have:

$$L \cong \frac{\pi\left(R_O^2 - R_I^2\right)}{T} \tag{8.5.241}$$

And for the more realistic case of a spiral:



We obviously have:

$$\begin{gathered}\rho = r + \varepsilon\frac{\theta}{2\pi}\\ R = r + n\varepsilon\end{gathered} \tag{8.5.242}$$

and:

$$\begin{cases} x = \rho\cos(\theta)\\ y = \rho\sin(\theta)\end{cases} \tag{8.5.243}$$

Hence:

$$\left\{\begin{aligned}\frac{\mathrm{d}x}{\mathrm{d}\theta}&=\frac{\varepsilon}{2\pi}\cos(\theta)-\left(r+\varepsilon\frac{\theta}{2\pi}\right)\sin(\theta)\\\frac{\mathrm{d}y}{\mathrm{d}\theta}&=\frac{\varepsilon}{2\pi}\sin(\theta)+\left(r+\varepsilon\frac{\theta}{2\pi}\right)\cos(\theta)\end{aligned}\right.\tag{8.5.244}$$

And this gives us:

$$\frac{\mathrm{d}L}{\mathrm{d}\theta}=\sqrt{\left(\frac{\mathrm{d}x}{\mathrm{d}\theta}\right)^2+\left(\frac{\mathrm{d}y}{\mathrm{d}\theta}\right)^2}=\sqrt{\left(\frac{\varepsilon}{2\pi}\right)^2+\left(r+\varepsilon\frac{\theta}{2\pi}\right)^2}=\frac{\varepsilon}{2\pi}\sqrt{1+\left(2\pi\frac{r}{\varepsilon}+\theta\right)^2}\tag{8.5.245}$$

Therefore:

$$\begin{aligned}L&=\int\limits_{\theta=0}^{\theta=2\pi n}\left(\frac{\mathrm{d}L}{\mathrm{d}\theta}\right)\mathrm{d}\theta=\frac{\varepsilon}{2\pi}\int\limits_{0}^{2\pi n}\sqrt{1+\left(2\pi\frac{r}{\varepsilon}+\theta\right)^2}\mathrm{d}\theta\\&=\frac{\varepsilon}{4\pi}\left(\left(2\pi\frac{r}{\varepsilon}+\theta\right)\sqrt{1+\left(2\pi\frac{r}{\varepsilon}+\theta\right)^2}+\ln\left(2\pi\frac{r}{\varepsilon}+\theta+\sqrt{1+\left(2\pi\frac{r}{\varepsilon}+\theta\right)^2}\right)\right)_{\theta=0}^{\theta=2\pi n}\\&=\frac{\varepsilon}{4\pi}\left(\left(2\pi\frac{r}{\varepsilon}+2\pi n\right)\sqrt{1+\left(2\pi\frac{r}{\varepsilon}+2\pi n\right)^2}-\left(2\pi\frac{r}{\varepsilon}\right)\sqrt{1+\left(2\pi\frac{r}{\varepsilon}\right)^2}+\ln\left(\frac{2\pi\frac{r}{\varepsilon}+2\pi n+\sqrt{1+\left(2\pi\frac{r}{\varepsilon}+2\pi n\right)^2}}{2\pi\frac{r}{\varepsilon}+\sqrt{1+\left(2\pi\frac{r}{\varepsilon}\right)^2}}\right)\right)\end{aligned}\tag{8.5.246}$$

and as $R=r+n\varepsilon$, this last relation simplifies to:

$$\begin{aligned}L&=\frac{\varepsilon}{4\pi}\left(2\pi\frac{R}{\varepsilon}\sqrt{1+\left(2\pi\frac{R}{\varepsilon}\right)^2}-\left(2\pi\frac{r}{\varepsilon}\right)\sqrt{1+\left(2\pi\frac{r}{\varepsilon}\right)^2}+\ln\left(\frac{2\pi\frac{R}{\varepsilon}+\sqrt{1+\left(2\pi\frac{R}{\varepsilon}\right)^2}}{2\pi\frac{r}{\varepsilon}+\sqrt{1+\left(2\pi\frac{r}{\varepsilon}\right)^2}}\right)\right)\\&=\pi\frac{R^2}{\varepsilon}\sqrt{1+\left(\frac{\varepsilon}{2\pi R}\right)^2}-\pi\frac{r^2}{\varepsilon}\sqrt{1+\left(\frac{\varepsilon}{2\pi r}\right)^2}+\frac{\varepsilon}{2\pi}\ln\left(\frac{R}{r}\right)+\frac{\varepsilon}{4\pi}\ln\left(\frac{1+\left(\frac{\varepsilon}{2\pi R}\right)^2\sqrt{1+\left(\frac{\varepsilon}{2\pi R}\right)^2}}{1+\left(\frac{\varepsilon}{2\pi r}\right)^2\sqrt{1+\left(\frac{\varepsilon}{2\pi r}\right)^2}}\right)\end{aligned}\tag{8.5.247}$$

If ε is small compared to r and R, let us see that we fall back on:

$$L\cong\pi\frac{R^2}{\varepsilon}-\pi\frac{r^2}{\varepsilon}=\frac{\pi(R^2-r^2)}{\varepsilon}\tag{8.5.248}$$

8.5.2.9 Equation of a Hypocycloid

In geometry, a hypocycloid is a special plane curve generated by the trace of a fixed point on a small circle that rolls within a larger circle. It is comparable to the cycloid or epicycloid but instead of the circle rolling along a line, it rolls within a circle.

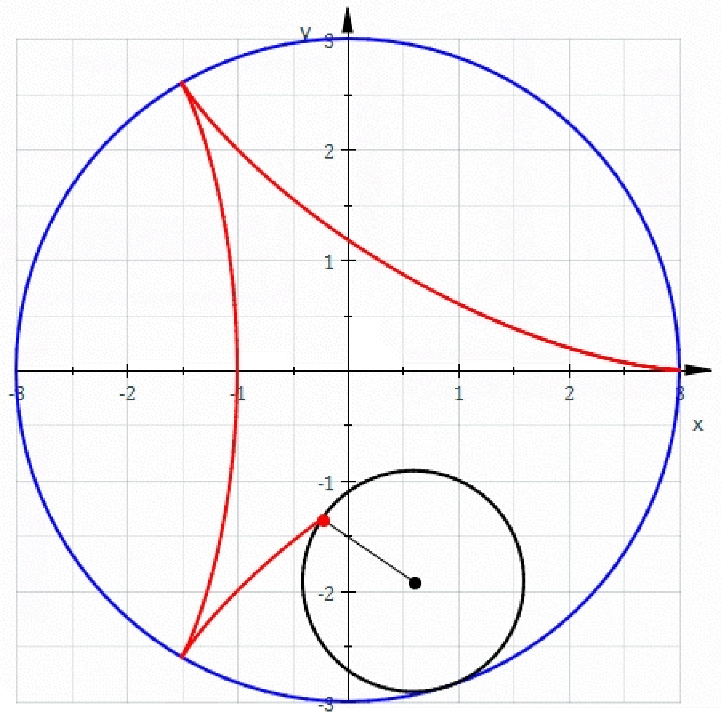


Figure 8.172: **Hypocycloid path (source: Wikipedia, Sam Derbyshire)**

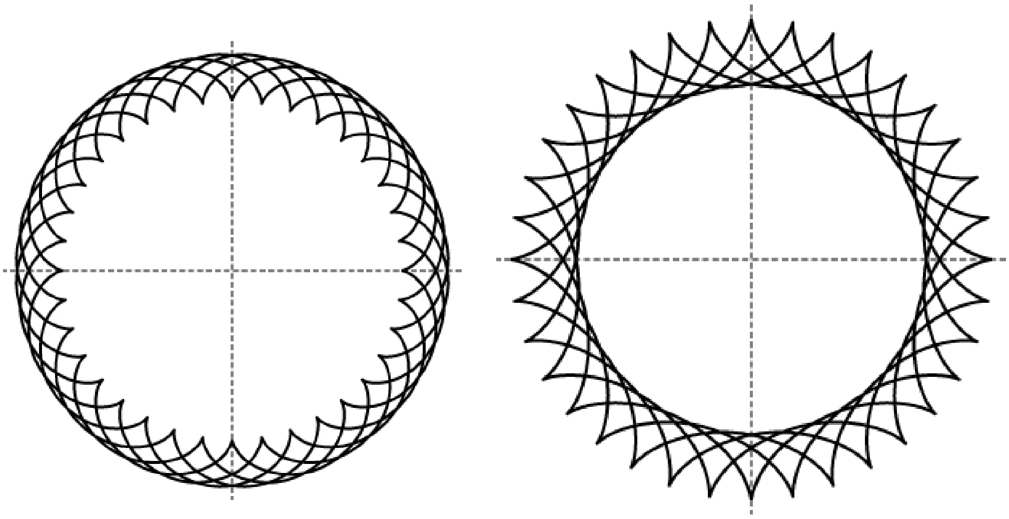
When we know the parametric equation of the epicycloid, that of the hypocycloid is immediate:

$$\boxed{\begin{aligned} x &= (R-r)\cos\theta + r\cos\left(\frac{R-r}{r}\theta\right) \\ y &= (R-r)\sin\theta + r\sin\left(\frac{R-r}{r}\theta\right) \end{aligned}} \tag{8.5.249}$$

Now for the section of Mechanical Engineering it will help if the reader compare side by side and epicycloid and a hypocycloid one:



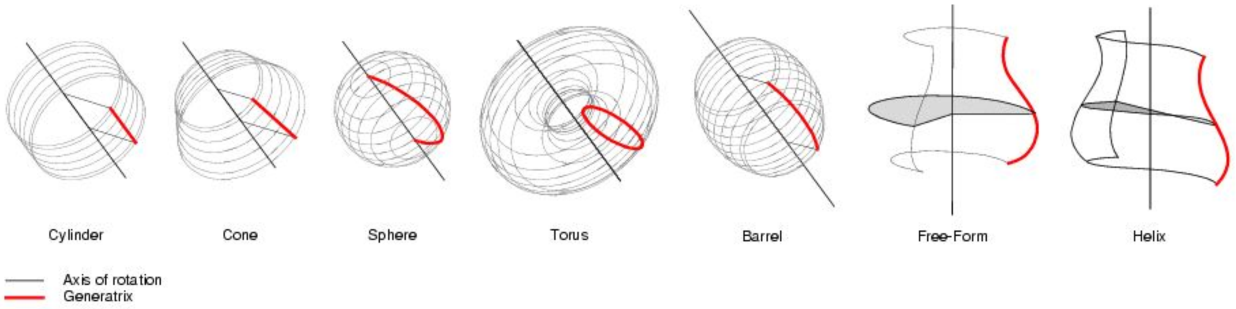
(a) **Epicycloid (source: Wikipedia)**

(b) **Hipocycloid**

8.5.2.10 Surface of revolution

More generally many surfaces (and also some of which we've seen before as the sphere, tore and cylinder) can be described by revolving a primary form of smaller size and then by rotation.

Definition (#8.5.357): A "surface of revolution" is a surface obtained by rotating a plane curve (e.g. $z=f(x)$), named the "generatrix", around the z-axis (for example!). So we pass from a plane of $\mathbb{R}^2$ to a basis in $\mathbb{R}^3$, the x-axis then generates a plane that has become the yOz plane.

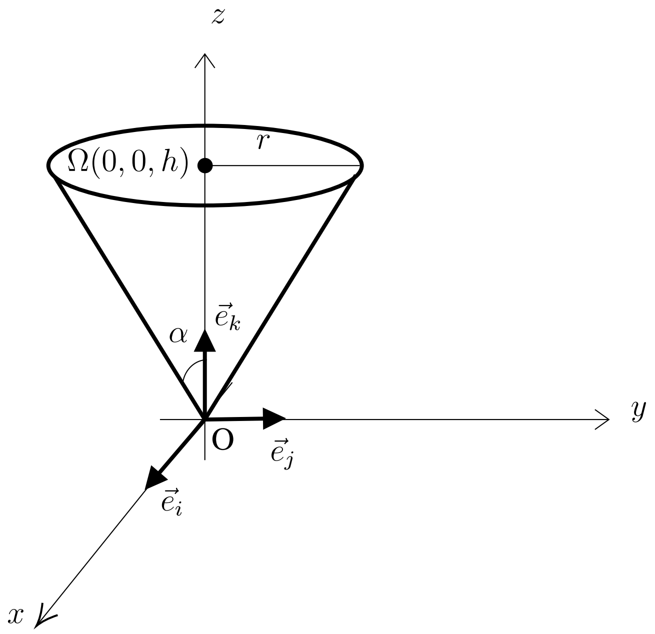


Cylinder
Cone
Sphere
Torus
Barrel
Free-Form
Helix
Axis of rotation
Generatrix

Let us see seven (cone, sphere, ellipsoid, cylinder, paraboloid, hyperboloid, torus) famous cases:

8.5.2.10.1 Cone

Consider a circular cone of vertex O (origin) with a circle of center $(0,0,h)$ (where h is a positive real number corresponding to the height of the cone) and radius R:



z
r
$\Omega(0,0,h)$
α
$\vec{e}_k$
y
O
$\vec{e}_j$
$\vec{e}_i$
x

Figure 8.174: **Representation of a cone**

A parametric representation of the circle at the height h is given as we already proved earlier by:

$$\begin{cases} x(t)=r\cos(t) \\ y(t)=r\sin(t) \\ z(t)=h \end{cases} \tag{8.5.250}$$

where t belongs to the interval $[-\pi,\pi]$.

By extension, the parametric representation of a cone is:

$$\begin{cases} x(t,k)=kr\cos(t) \\ y(t,k)=kr\sin(t) \\ z(t,k)=kh \end{cases} \tag{8.5.251}$$

this can also be written in vector form (more traditional):

$$\boxed{\begin{pmatrix} x(t,k) \\ y(t,k) \\ z(t,k) \end{pmatrix} = \begin{pmatrix} kr\cos(t) \\ kr\sin(t) \\ kh \end{pmatrix}} \tag{8.5.252}$$

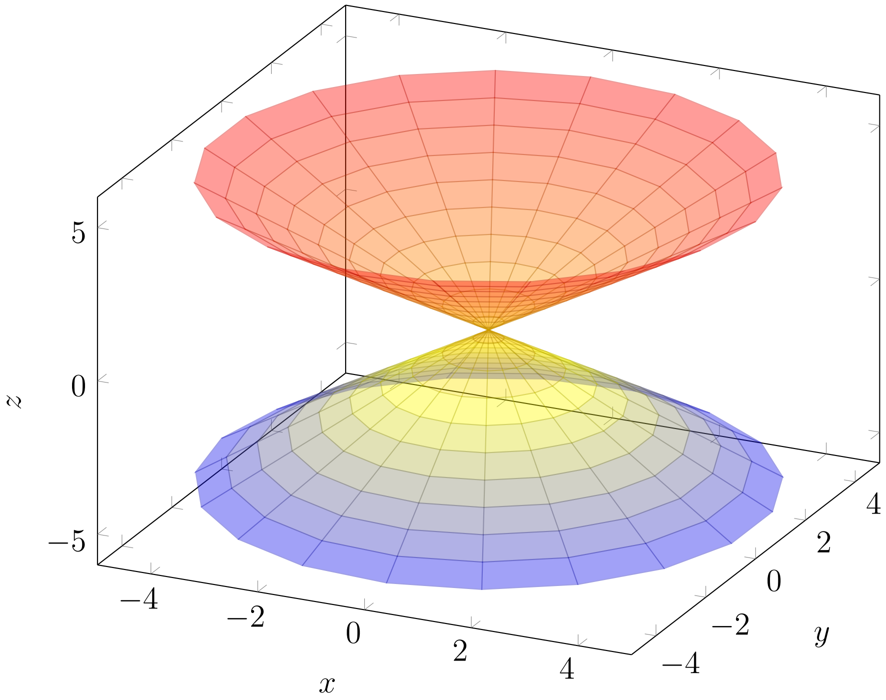


Figure 8.175: **High definition Cone made with LaTeX/Tikz**

In other words, the circle linearly propagates in all directions.

✍**Example:**

With Maple™ 4.00b:

```
>r:=1:h:=4:
>plot3d([k*r*cos(t),k*r*sin(t),k*h],k=0..10,t=0..2*Pi,
orientation=[50,60],style=PATCH,axes=NORMAL);
```

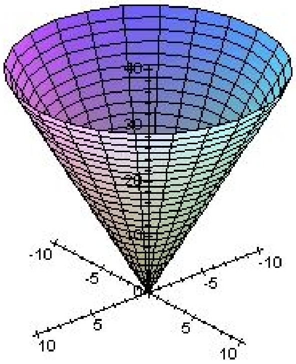

Figure 8.176: **Parametric representation of a cone in Maple™ 4.00b**

This suggests also the following cartesian equation of this cone:

$$x^2+y^2=k^2r^2=\left(\frac{z}{h}\right)^2r^2 \qquad (8.5.253)$$

As we have $\tan(\alpha)=r/h$ we can write:

$$x^2+y^2=\left(\frac{z}{h}\right)^2r^2=z^2\tan^2(\alpha)=0 \qquad (8.5.254)$$

Therefore:

$$\boxed{x^2+y^2-z^2\tan^2(\alpha)=0} \qquad (8.5.255)$$

which is the Cartesian equation of a cone in space that we will see again in the section of Special Relativity in our study of light cones.

8.5.2.10.2 Sphere

Consider the orthonormal basis $\{\vec{i},\vec{j},\vec{k}\}$. Given the sphere $\mathcal{S}^2$ of center $\Omega(a,b,c)$ and of radius r:

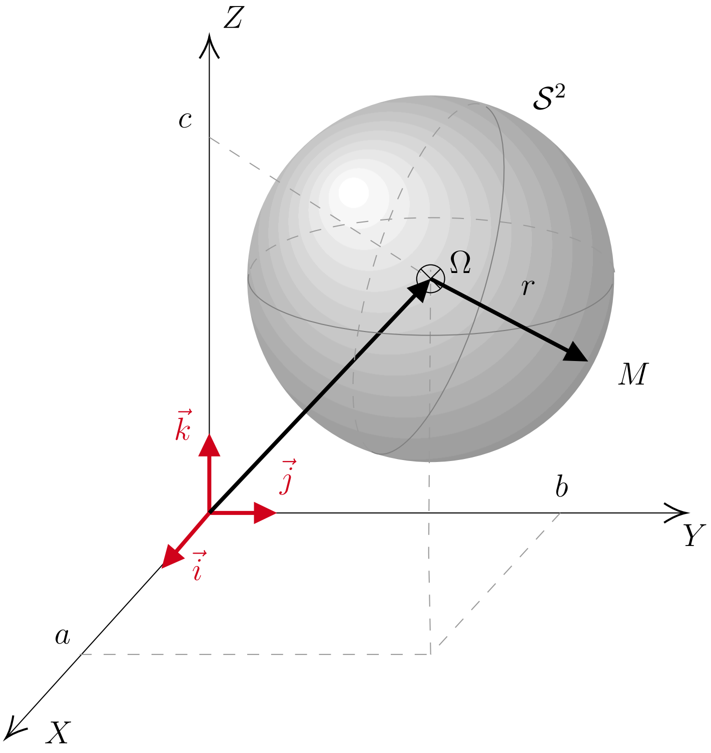

Figure 8.177: Representation of a $\mathcal{S}^2$ sphere

$M(x,y,z)$ belongs to the sphere S^2 of radius r if and only if:

$$\overline{\Omega M} = r \tag{8.5.256}$$

that is to say by applying Pythagoras theorem:

$$\overline{\Omega M} = r^2 = (x-a)^2 + (y-b)^2 + (z-c)^2 \tag{8.5.257}$$

Hence the "Cartesian equation of the sphere" in the basis $\{\vec{i},\vec{j},\vec{k}\}$:

$$\boxed{r^2 = (x-a)^2 + (y-b)^2 + (z-c)^2 = r^2} \tag{8.5.258}$$

There is another way to describe the sphere using the parametric equation. Indeed, we saw in the section of Vector Calculus that the transformation of the Cartesian coordinates to spherical coordinates is given by the following curvilinear coordinates:

$$x = r\sin(\theta)\cos(\phi),\; y = r\sin(\theta)\sin(\phi),\; z = r\cos(\theta) \tag{8.5.259}$$

Therefore we have well (by a change of variable this also represent a sphere not centered at the origin):

$$\begin{aligned} x^2+y^2+z^2 &= r^2\sin^2(\theta)\cos^2(\phi) + r^2\sin^2(\theta)\sin^2(\phi) + r^2\cos^2(\theta) \\ &= r^2\sin^2(\theta)(\cos^2(\phi)+\sin^2(\phi)) + r^2\cos^2(\theta) = r^2\sin^2(\theta) + r^2\cos^2(\theta) \\ &= r^2(\sin^2(\theta)+\cos^2(\theta)) = r^2 \end{aligned} \tag{8.5.260}$$

So the parametric equation of the sphere is indeed:

$$\boxed{\begin{pmatrix} x(\theta,\phi) \\ y(\theta,\phi) \\ z(\theta,\phi) \end{pmatrix} = \begin{pmatrix} r\sin(\theta)\cos(\phi) \\ r\sin(\theta)\sin(\phi) \\ r\cos(\theta) \end{pmatrix}} \tag{8.5.261}$$

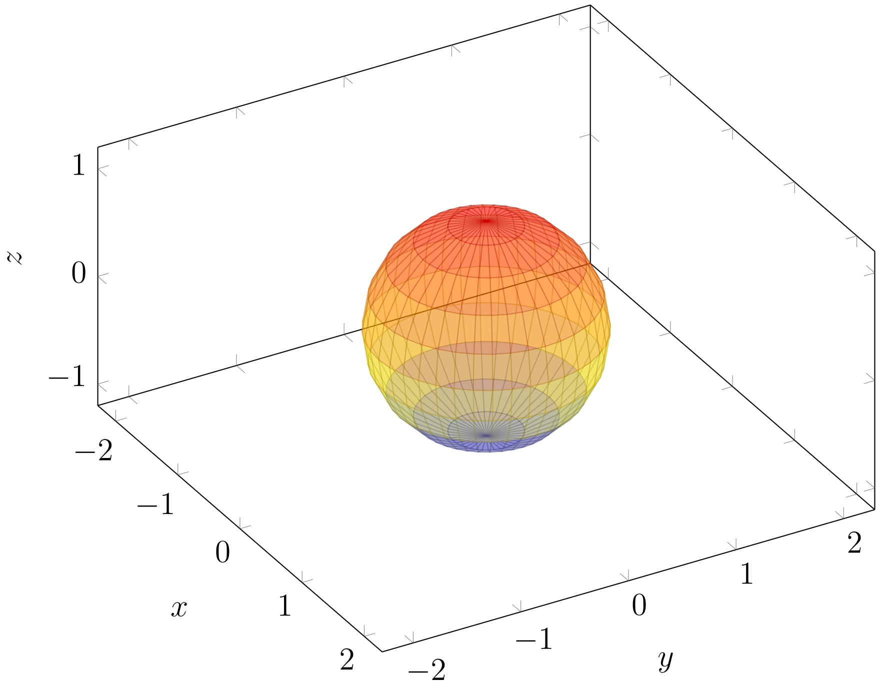

Figure 8.178: **High definition Sphere made with LaTeX/Tikz**

We fall back therefore on the Cartesian equation of a sphere to a given translation constant.

Example:

With Maple™ 4.00b for a sphere of unit radius:

```
>r:=1:h:=4:
>plot3d([sin(theta)*cos(phi),sin(theta)*sin(phi),cos(theta)],
theta=0..Pi,phi=-Pi..Pi,scaling=CONSTRAINED,orientation=[50,60],
style=PATCH,axes=NORMAL);
```

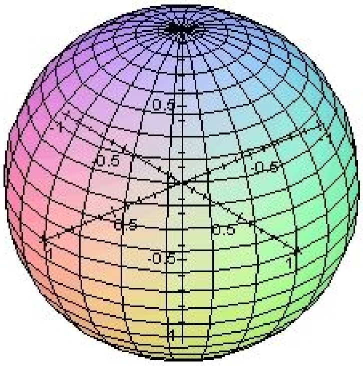

Figure 8.179: **Parametric representation of a sphere in Maple™ 4.00b**

8.5.2.10.2.1 Great circle of sphere

We will introduce here a concept that will be useful to us when we will study the geodesic of a sphere in the section of Analytical Mechanics.

Definition (#8.5.358): A "great circle", also known as an "orthodrome" or "Riemannian circle", of a sphere is the intersection of the sphere and a plane that passes through the center point of the sphere. This partial case of a circle of a sphere is opposed to a "small circle", the intersection of the sphere and a plane that does not pass through the center. Any diameter of any great circle coincides with a diameter of the sphere, and therefore all great circles have the same circumference as each other, and have the same center as the sphere. A great circle is the largest circle that can be drawn on any given sphere. Every circle in Euclidean 3-space is a great circle of exactly one sphere.

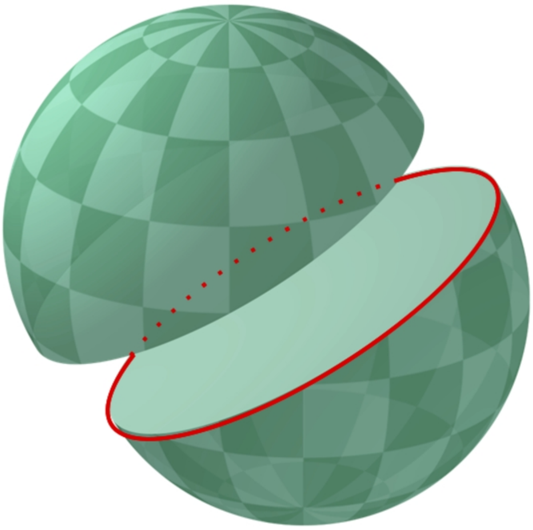

Figure 8.180: **A great circle divides the sphere in two equal hemispheres**

Let use choose now a unit normal vector to a plane passing through the origin using Euler angles be:

$$\vec{n}=\begin{pmatrix}-\sin(\gamma)\\0\\\cos(\gamma)\end{pmatrix} \tag{8.5.262}$$

where for rotated our such that the component n_2 is equal to 0 (as it is always possible to do so whatever the plan we choose that pass through the origin!).

If we choose a sphere of radius $r=1$ such that it's parametric equation is written as:

$$\vec{\mathcal{S}}^2=\begin{pmatrix}r\sin(\theta)\cos(\phi)\\r\sin(\theta)\sin(\phi)\\r\cos(\theta)\end{pmatrix}=\begin{pmatrix}\sin(\theta)\cos(\phi)\\\sin(\theta)\sin(\phi)\\\cos(\theta)\end{pmatrix} \tag{8.5.263}$$

And as the set of points that are at the intersection of the plane and the sphere are by construction such that:

$$\vec{\mathcal{S}}^2\circ\vec{n}=0 \tag{8.5.264}$$

Therefore we get:

$$-\sin(\gamma)\sin(\theta)\cos(\phi)+0\cdot\sin(\theta)\sin(\phi)+\cos(\gamma)\cos(\theta)=0 \tag{8.5.265}$$

After rearranging:

$$\frac{\sin(\gamma)}{\cos(\gamma)}\cos(\phi)=\frac{\cos(\theta)}{\sin(\theta)} \tag{8.5.266}$$

Let us put:

$$a=\frac{\sin(\gamma)}{\cos(\gamma)} \tag{8.5.267}$$

and using the definition of the cotangent:

$$\boxed{a\cos(\phi)=\cot(\theta)} \tag{8.5.268}$$

This is therefore the "equation of a great circle".

8.5.2.10.2.2 n-Sphere volume

Before we deal with the subject, we want to thanks professor Howard Haber that has provided us the major LaTeXsource code of the text below that will be useful to us in the sections of Statistical Mechanics (especially to derive the Sackur-Tetrode equation) and of General Relativity!

An n-dimensional hypersphere of radius R consists of the locus of points such that the distance from the origin is less than or equal to R.

A point in an n-dimensional Euclidean space is designated by $(x_1\,,\,x_2\,,\,\ldots\,,\,x_n)$.

In equation form, the hypersphere corresponds then by definition to the set of points such that:

$$x_1^2+x_2^2+\cdots+x_n^2\leq R^2 \tag{8.5.269}$$

To compute the volume of this hypersphere, we simply integrate the infinitesimal volume element $\mathrm{d}V=\mathrm{d}x_1\mathrm{d}x_2\cdots\mathrm{d}x_n$ over the region of n-dimensional space indicated by 8.5.269. We wish to compute this volume $V_n(R)$. Explicitly:

$$V_n(R)=\int\ldots\int_{x_1^2+x_2^2+\cdots+x_n^2\leq R^2}\mathrm{d}x_1\mathrm{d}x_2\cdots\mathrm{d}x_n=C_nR^n \tag{8.5.270}$$

The factor of R^n is a consequence of dimensional analysis.

The surface-area of the n-dimensional hypersphere will be denoted in what follows by $S_{n-1}(R)$.

The surface of the hypersphere corresponds to the locus of points such that:

$$x_1^2+x_2^2+\cdots+x_n^2=R^2 \tag{8.5.271}$$

We can construct the volume $V_n(R)$ by adding infinitely thin spherical shells of radius $0 \leq r \leq R$. In equation form, this reads:

$$V_n(R) = \int_0^R S_{n-1}(r)\mathrm{d}r \tag{8.5.272}$$

And as we know:

$$S_{n-1}(R) = \frac{\mathrm{d}V_n(R)}{\mathrm{d}R} = nC_nR^{n-1} \tag{8.5.273}$$

where we have used 8.5.270. Thus, the only remaining task is to compute C_n.

In order to obtain a better intuition on the meaning of C_n, let us equate the two expressions we have for $V_n(R)$, namely 8.5.270 and 8.5.271.

In the latter, $S_{n-1}(r)$ is determined by 8.5.273. Thus:

$$V_n(R) = \int\!\cdots\!\int_{x_1^2+x_2^2+\cdots+x_n^2 \leq R^2} \mathrm{d}x_1\mathrm{d}x_2\cdots\mathrm{d}x_n = nC_n\int_0^R r^{n-1}\,\mathrm{d}r \tag{8.5.274}$$

This last relation is simply the evaluation of an n-dimensional integral either in rectangular co-ordinates or hyper-spherical co-ordinates. In n-dimensions, we would write:

$$\mathrm{d}x_1\,\mathrm{d}x_2\cdots\mathrm{d}x_n = r^{n-1}\,\mathrm{d}r\,\mathrm{d}\Omega_{n-1} \tag{8.5.275}$$

where $\mathrm{d}\Omega_{n-1}$ contains all of the angular factors. For example, for $n=2$, $\mathrm{d}\Omega_1 = \mathrm{d}\theta$; for $n=3$, $\mathrm{d}\Omega_2 = \sin(\theta)\,\mathrm{d}\theta\,\mathrm{d}\phi$, etc.

One could explicitly define the $n-1$ angular variables in n-dimensions.

However, if we are integrating over a spherically symmetric function, then we will simply integrate over $\mathrm{d}\Omega_{n-1}$. Comparing 8.5.274 and 8.5.275, we see that:

$$\int\!\cdots\!\int \mathrm{d}\Omega_{n-1} = nC_n \tag{8.5.276}$$

We will present a trick for computing C_n without ever explicitly parametrizing the angles of the hyper-spherical coordinate system. For this purpose, consider the function:

$$f(x_1\,,\,x_2\,,\,\ldots\,,\,x_n) = e^{-(x_1^2+x_2^2+\cdots+x_n^2)} = e^{-r^2} \tag{8.5.277}$$

If we integrate this function over the full n-dimensional space in both rectangular and hyper-spherical coordinates, we obtain:

$$\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}\cdots\int_{-\infty}^{+\infty} e^{-(x_1^2+x_2^2+\cdots+x_n^2)}\mathrm{d}x_1\mathrm{d}x_2\cdots\mathrm{d}x_n = \int_0^{+\infty} r^{n-1}\,\mathrm{d}r\int \mathrm{d}\Omega_{n-1}e^{-r^2} \tag{8.5.278}$$

Since the integrand on the right hand side depends only on r (there is no angular dependence), we can immediately perform the integral over $\mathrm{d}\Omega_{n-1}$. Using 8.5.276:

$$\int_{-\infty}^{+\infty} e^{-x_1^2}\,\mathrm{d}x_1\int_{-\infty}^{+\infty} e^{-x_2^2}\mathrm{d}x_2\ldots\int_{-\infty}^{+\infty} e^{-x_n^2}\mathrm{d}x_n = nC_n\int_0^{+\infty} r^{n-1}\,e^{-r^2}\mathrm{d}r \tag{8.5.279}$$

All the integrals above can be evaluated exactly using Gauss integral (see section Statistics page 695) and Euler-Gamma integral (see section Differential and Integral Calculus page 1574):

$$\begin{gathered}\int\limits_{-\infty}^{+\infty} e^{-x^2}\,\mathrm{d}x=\sqrt{\pi}\\ \int\limits_{0}^{+\infty} r^{n-1}\,e^{-r^2}\,\mathrm{d}r=\int\limits_{0}^{+\infty} e^{-t}t^{\frac{n-1}{2}}\left(\frac{1}{2}t^{-1/2}\mathrm{d}t\right)=\frac{1}{2}\Gamma\left(\frac{n}{2}\right)\end{gathered}\tag{8.5.280}$$

Inserting these results into 8.5.279, we get :

$$\pi^{n/2}=C_n\,\frac{n}{2}\,\Gamma\left(\frac{n}{2}\right)=C_n\,\Gamma\left(1+\frac{n}{2}\right)\tag{8.5.281}$$

where we used the property of the Gamma function, $x\Gamma(x)=\Gamma(x+1)$, at the final step. Solving for C_n, we get:

$$C_n=\frac{\pi^{n/2}}{\Gamma\left(1+\dfrac{n}{2}\right)}\tag{8.5.282}$$

Although we chose a particular function $f(x_1\,,\,x_2\,,\,\ldots\,,\,x_n)$ to get the final result for C_n, it is clear that the value of C_n is independent of this function. After all, the defining equation for C_n as in 8.5.276 makes no reference to any function. As a check, let us evaluate $n\,C_n$ for $n=2$ and $n=3$:

$$\begin{gathered}2\,C_2=\frac{2\pi}{\Gamma(2)}=2\pi=\int\limits_0^{2\pi}\mathrm{d}\theta\\ 3\,C_3=\frac{3\pi^{3/2}}{\Gamma\left(\dfrac{5}{2}\right)}=4\pi=\int\limits_0^{2\pi}\mathrm{d}\phi\int\limits_0^{\pi}\sin\theta\mathrm{d}\theta\end{gathered}\tag{8.5.283}$$

In the last computation, we used $\Gamma\left(\frac{5}{2}\right)=\frac{3}{2}\Gamma\left(\frac{3}{2}\right)=\left(\frac{3}{2}\right)\left(\frac{1}{2}\right)\Gamma\left(\frac{1}{2}\right)=\frac{3}{4}\sqrt{\pi}$. Indeed, we have produced the correct values for the integration over the angular factors in two and three dimensions.

We are finally ready to compute the volume and surface-area of an n-dimensional hypersphere. Inserting 8.5.282 into 8.5.270 and 8.5.273, we find:

$$\boxed{\begin{aligned}V_n(R)&=\frac{\pi^{n/2}\,R^n}{\Gamma\left(1+\dfrac{n}{2}\right)}\\ S_{n-1}(R)&=\frac{n\pi^{n/2}\,R^{n-1}}{\Gamma\left(1+\dfrac{n}{2}\right)}\end{aligned}}\tag{8.5.284}$$

The expression for $S_n(R)$ can be slightly simplified by writing $\Gamma\left(1+\dfrac{n}{2}\right)=\dfrac{n}{2}\,\Gamma\left(\dfrac{n}{2}\right)$. This yields:

$$\boxed{S_{n-1}(R)=\frac{2\pi^{n/2}\,R^{n-1}}{\Gamma\left(\dfrac{n}{2}\right)}}\tag{8.5.285}$$

You should check that you get the expected results for $n = 2$ and $n = 3$. For example,$V_3(R) = \frac{4}{3}\pi R^3$ and $S_2(R) = 4\pi R^2$.

Finally, it is amusing to note that $\lim_{n\rightarrow+\infty} V_n(R) = 0$ and $\lim_{n\rightarrow+\infty} S_n(R) = 0$.

To understand this peculiar behaviour, consider a hypercube in n-dimensional space measuring one unit on each side. The total volume of this hypercube is 1. We can fit a hypersphere of diameter 1 (or radius $\frac{1}{2}$) inside the hypercube such that the surface of the hypersphere just touches each of the walls of the hypercube. Then $1 - V_n(\frac{1}{2})$ is the volume inside the cube but outside the hypersphere.

In particular, as n becomes large, $1 - V_n(\frac{1}{2})$ rapidly approaches 1, which is consistent with the assertion that $\lim_{n\rightarrow+\infty} V_n(R) = 0$. This simply means that as the number of dimensions becomes larger and larger, the amount of space outside the hypersphere (but inside the cube) is become relatively more and more important. This is already happening as you go from 2 to 3 dimensions. So you can check your intuition by inscribing a circle in a unit square and a sphere in a unit cube and computing the total volume in three dimensions (area in two dimensions) outside the sphere (circle) but inside the cube (square). If you take the ratio of volumes (areas) of the sphere (circle) to that of the cube (square), this ratio actually *decreases* as you go from 2 dimensions to 3 dimensions!

This shows that the integer dimension with maximum integer coefficient is $n = 5$.

Dimension	**Volume**	**Volume at $r = 1$**
2	πr^2	3.14159
3	$4/3\pi r^3$	4.18879
4	$1/2\pi^2 r^4$	4.93480
5	$8/15\pi^2 r^5$	5.26379
6	$1/6\pi^3 r^6$	5.16771
7	$16/105\pi^3 r^7$	4.72477
8	$1/24\pi^4 r^8$	4.05871
9	$32/945\pi^4 r^9$	3.29851

8.5.2.10.3 Ellipsoid (spheroid)

We saw in our study of conic that the cartesian equation of an ellipse in the plane was given by:

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1 \tag{8.5.286}$$

with a, b the two axes of the ellipse (small and large one).

Thus, without rigorous proof, we can verify by hand or using computers that the Cartesian equation:

$$\boxed{\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{b^2}=1} \tag{8.5.287}$$

is an ellipsoid:

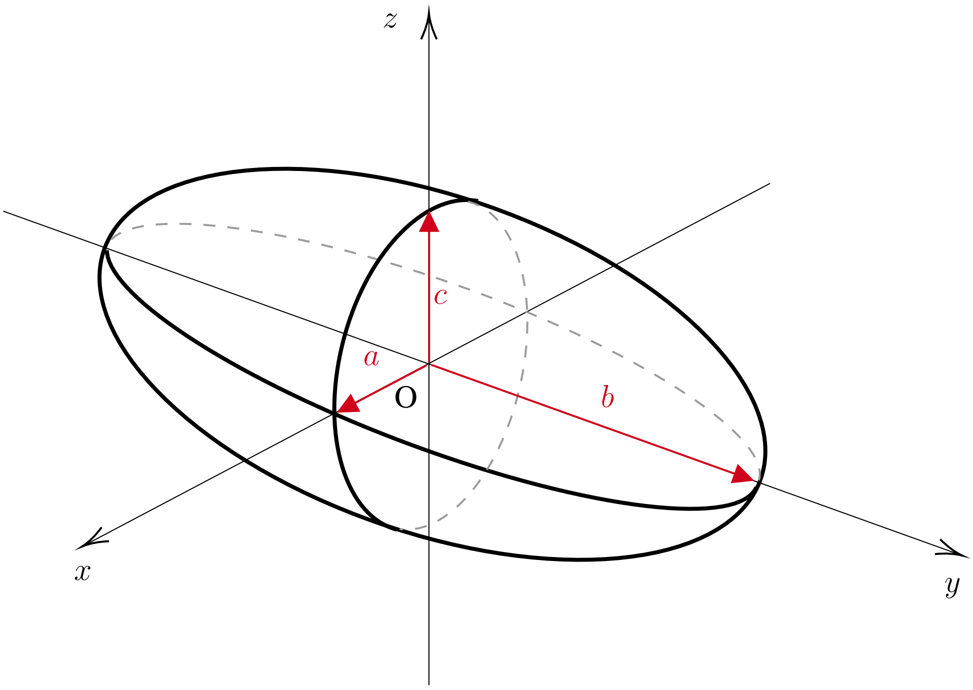

Figure 8.181: **Representation of an ellipsoid**

However, there is another way of describing an ellipsoid using also curvilinear coordinates:

$$x=a\cos(\theta)\cos(\phi), y=b\cos(\theta)\sin(\phi), z=c\sin(\theta) \tag{8.5.288}$$

So the parametric equation of an ellipsoid will be:

$$\boxed{\begin{pmatrix}x(\theta,\phi)\\y(\theta,\phi)\\z(\theta,\phi)\end{pmatrix}=\begin{pmatrix}a\cos(\theta)\cos(\phi)\\b\cos(\theta)\sin(\phi)\\c\sin(\theta)\end{pmatrix}} \tag{8.5.289}$$

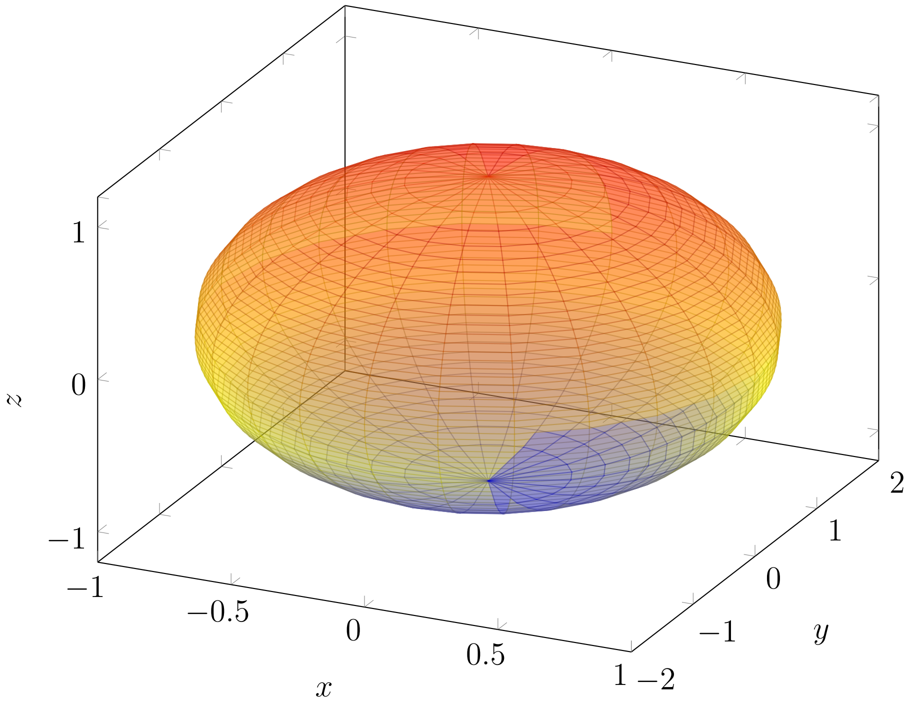

Figure 8.182: **High definition Ellipsoid made with LaTeX/Tikz**

We can see that this is simply the parametric equation of a sphere but with different radii along the axes of the chosen basis.

Example:

With Maple™ 4.00b:

```
>a:=100:b:=2:c:=20:
>plot3d([a*cos(theta)*cos(lambda),b*cos(theta)*sin(lambda),
c*sin(theta)],lambda=0..Pi,theta=-Pi..Pi,orientation=[50,60],
style=PATCH,axes=NORMAL);
```

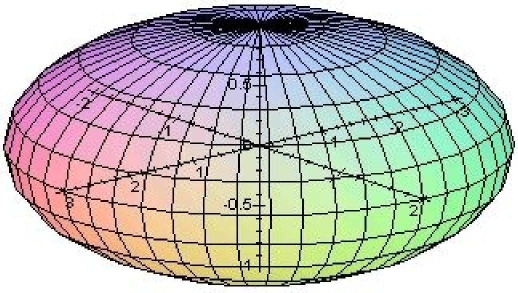

Figure 8.183: **Parametric representation of an ellipsoid in Maple™ 4.00b**

So we have:

$$x^2=a^2\cos^2(\theta)\cos^2(\phi),y^2=b^2\cos^2(\theta)\sin^2(\phi),z^2=c^2\sin^2(\theta) \tag{8.5.290}$$

hence:

$$\begin{aligned}\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}&=\cos^2(\theta)\cos^2(\phi)+\cos^2(\theta)\sin^2(\phi)+\sin^2(\theta)=\cos^2(\theta)(\cos^2(\phi)+\sin^2(\phi))+\sin^2(\theta)\\&=\cos^2(\theta)+\sin^2(\theta)=1\end{aligned} \tag{8.5.291}$$

Finally:

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1 \tag{8.5.292}$$

In astronomy (see section Astronomy page 5217) the ellipsoid is mainly named "oblate spheroid".

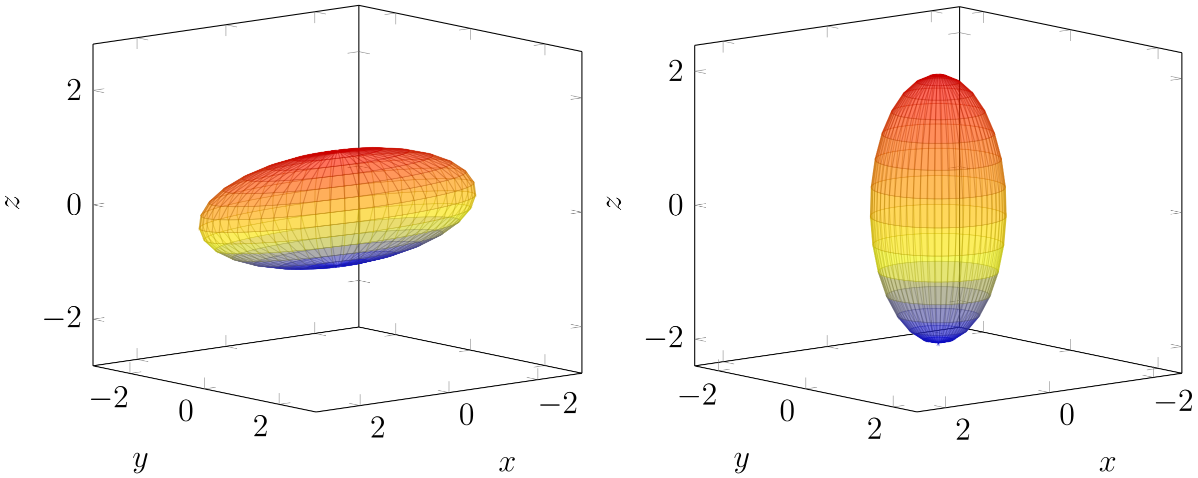

Figure 8.184: Oblate spheroid (on the left), Prolate spheroid (on the right)

and we have technically a oblate spheroid when $c<a$ and prolate one when $c>a$. Obviously the case $a=c$ reduces to a sphere.

Remark

Because of the combined effects of gravity and rotation, the Earth's shape is not quite a sphere but instead is slightly flattened in the direction of its axis of rotation. For that reason, in cartography the Earth is often approximated by an oblate spheroid instead of a sphere. The actual World Geodetic System model uses a spheroid whose radius is $6,378.137$ [km] at the equator and $6,356.752$ [km] at the poles.

The aspect ratio of an oblate spheroid/ellipse, $b:a$, is the ratio of the polar to equatorial lengths, while the flattening (also named "oblateness") f, is the ratio of the equatorial-polar length difference to the equatorial length:

$$f=\frac{a-b}{a}=1-\frac{b}{a} \tag{8.5.293}$$

8.5.2.10.4 Cylinder

It goes without saying that the parametric equation of a cylinder of radius r is given by:

$$\boxed{\begin{pmatrix} x(\phi) \\ y(\phi) \\ z \end{pmatrix} = \begin{pmatrix} r\cos(\phi) \\ r\sin(\phi) \\ z \end{pmatrix}} \qquad (8.5.294)$$

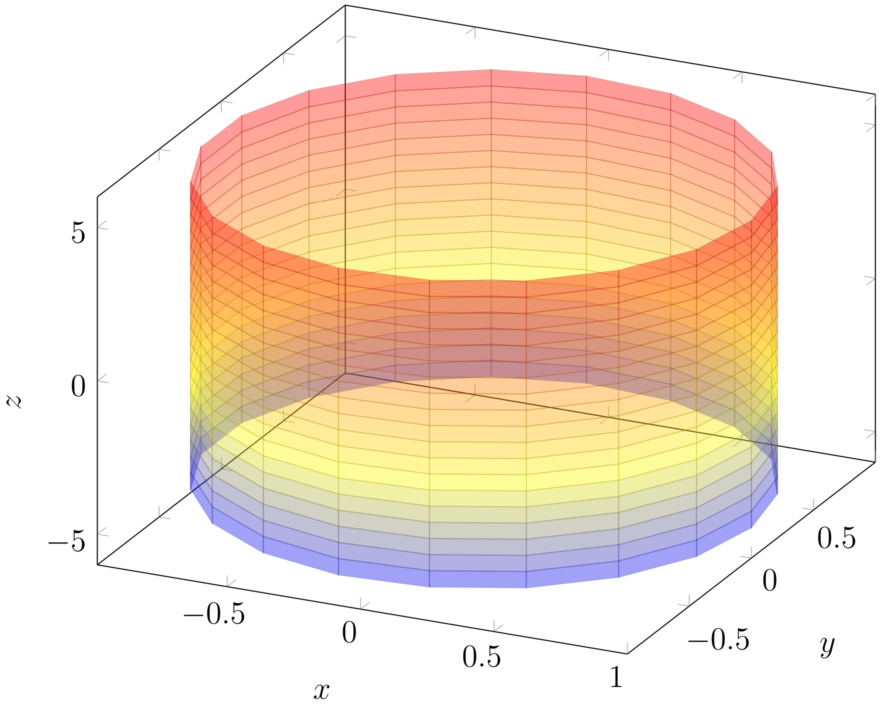

Figure 8.185: **High definition Cylinder made with LaTeX/Tikz**

We see well that the components x, y satisfy the Cartesian equation of a circle for every z since:

$$x^2 + y^2 = r^2 \qquad (8.5.295)$$

✍**Example:**

With Maple™ 4.00b a cylinder of radius $r = 1$:

```
>plot3d([cos(phi),sin(phi),z],phi=-Pi..Pi,z=0..2,orientation=[50,60],
style=PATCH,axes=NORMAL);
```

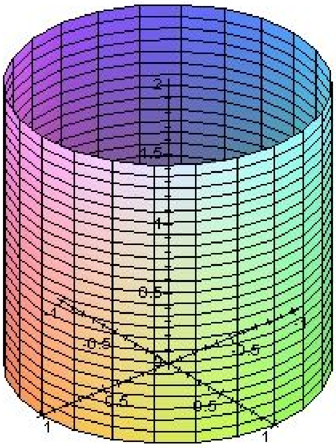

Figure 8.186: **Parametric representation of a cylinder in Maple™ 4.00b**

It is obvious that the parametric equation of an elliptical base cylinder is given by:

$$\boxed{\begin{pmatrix} x(\phi) \\ y(\phi) \\ z \end{pmatrix} = \begin{pmatrix} a\cos(\phi) \\ b\sin(\phi) \\ z \end{pmatrix}} \tag{8.5.296}$$

which also satisfies the parametric equation of an ellipse in the plane:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \tag{8.5.297}$$

8.5.2.10.5 Paraboloid

Given the equation of the parabola around the z-axis:

$$z=\frac{x^2}{2p} \tag{8.5.298}$$

with for reminder:

$$p=eh \tag{8.5.299}$$

We have obviously (by cutting the paraboloid by a horizontal plane which gives therefore a circle of radius r) the relation:

$$z=\frac{r^2}{2p} \tag{8.5.300}$$

named "cylinder equation". But we also have by applying the Pythagorean theorem in the circle above:

$$r^2=x^2+y^2 \tag{8.5.301}$$

Therefore:

$$x^2+y^2=2pz \tag{8.5.302}$$

Hence we get the "Cartesian equation of the paraboloid (of revolution)":

$$z=\frac{1}{2}\left(\frac{1}{p}x^2+\frac{1}{p}y^2\right) \tag{8.5.303}$$

We build the parametric equation of the paraboloid exactly in the same way as for the cone, at the difference that the evolution along the z-axis will not be linear relatively to a parameter k but to the square of the latter. Therefore we have:

$$\boxed{\begin{pmatrix} x(t,k) \\ y(t,k) \\ z(k) \end{pmatrix}=\begin{pmatrix} kr\cos(t) \\ kr\sin(t) \\ kh^2 \end{pmatrix}=\begin{pmatrix} k\dfrac{1}{2p}\cos(t) \\ k\dfrac{1}{2p}\sin(t) \\ kh^2 \end{pmatrix}} \tag{8.5.304}$$

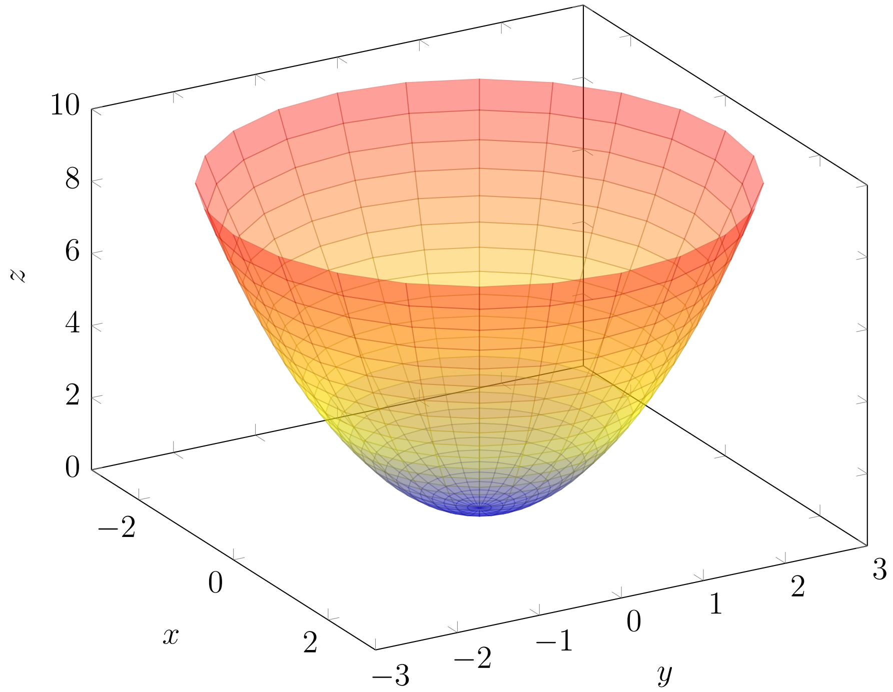

Figure 8.187: **High definition Paraboloid made with LaTeX/Tikz**

✍**Example:**

With Maple™ 4.00b a paraboloid with $h = 1, p = 1$:

```
>p:=1:h:=1:
>plot3d([k*1/(2*p)*cos(t),k*1/(2*p)*sin(t),k^2*h],k=0..10,
t=0..2*Pi,orientation=[50,60],style=PATCH,axes=NORMAL);
```

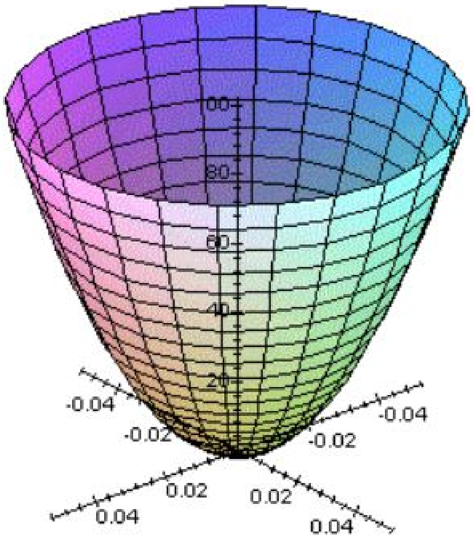

Figure 8.188: **Parametric representation of a paraboloid in Maple™ 4.00b**

8.5.2.10.6 Hyperboloid

Given the linear function:

$$z=x \tag{8.5.305}$$

that we turn around the z-axis. As the line passes trough the origin, the revolution around the z-axis is similar to two cones facing each other with their apex at the origin O. Therefore:

$$z^2=x^2+y^2 \tag{8.5.306}$$

which gives us obviously:

$$x^2+y^2-z^2=0 \tag{8.5.307}$$

Definition (#8.5.359): Any surface generated by a line is a "ruled surface". More explicitly a surface S is ruled if through every point of S there is a straight line that lies on S. A ruled surface S is a curved surface which can be generated by the continuous motion of a straight line in space along a space curve named the "directrix".

Let us take an important example (nuclear central chimney shape, gears, etc.) that is the "hyperboloid of one sheet" of equation:

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=1 \tag{8.5.308}$$

More often denoted as:

$$-\frac{x^2}{a^2}-\frac{y^2}{b^2}+\frac{z^2}{c^2}=1 \tag{8.5.309}$$

Or as:

$$\frac{z^2}{c^2}-\left(\frac{x^2}{a^2}+\frac{y^2}{b^2}\right)=1 \tag{8.5.310}$$

If we put $a=b=c=1$ we have therefore (rotated line around the z axis but not going through the origin O):

$$x^2+y^2-z^2=1\Leftrightarrow x^2-z^2=1-y^2 \tag{8.5.311}$$

which can also be written as the product of the equation of two lines such that:

$$(x-z)(x+z)=(1-y)(1+y) \tag{8.5.312}$$

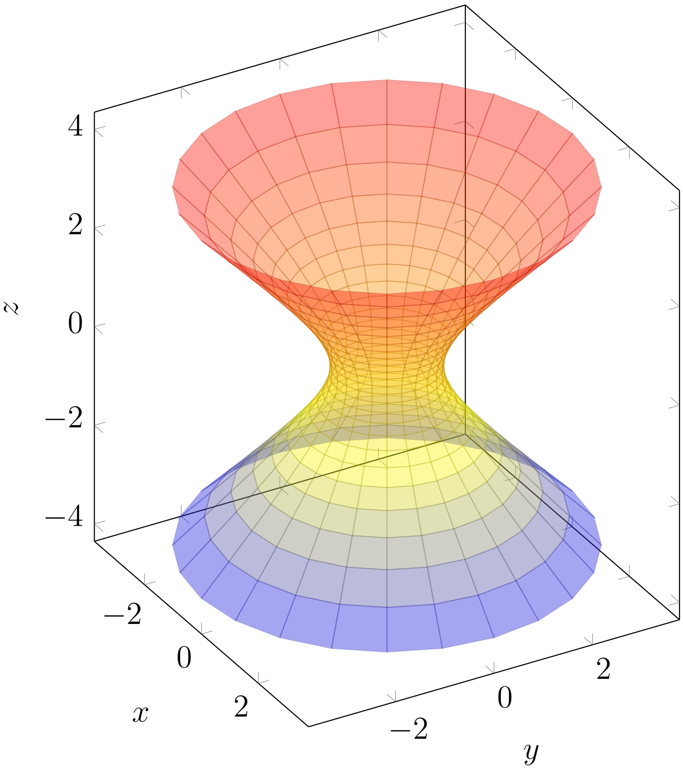

Figure 8.189: **High definition Hyperboloid of one sheet made with LaTeX/Tikz**

That we can also rewrite with $k \in \mathbb{R}$:

$$(x-z)k(x+z)=k(1-y)(1+y) \tag{8.5.313}$$

by identification:

$$\text{D1}: x-z=k(1-y) \tag{8.5.314}$$
$$\text{D2}: 1+y=k(x+z) \tag{8.5.315}$$

It is not trivial but these to two lines belong to the same surface and any point belonging to one of these two lines is contained therein. The figures below show well that fact, every point belongs to these two lines:

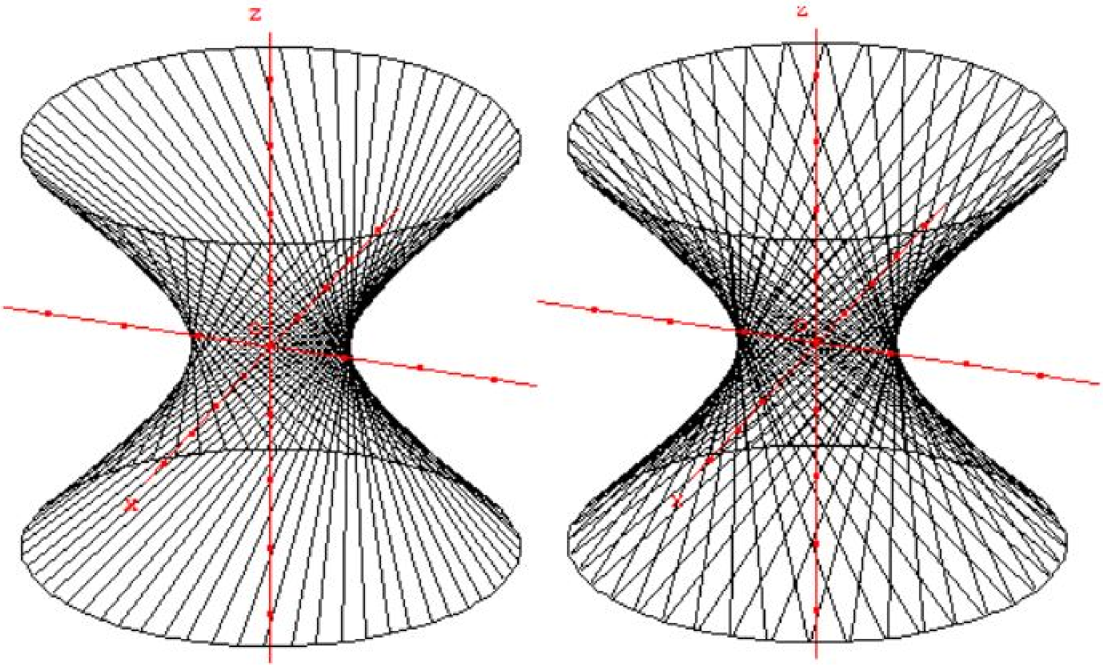

Figure 8.190: **Hyperbolic Rules Surface**

We could also describe this by circles such that (this is the traditional way on computers):

$$x^2+y^2-z^2=1 \leftrightarrow x^2+y^2=(1+z^2)=r^2 \tag{8.5.316}$$

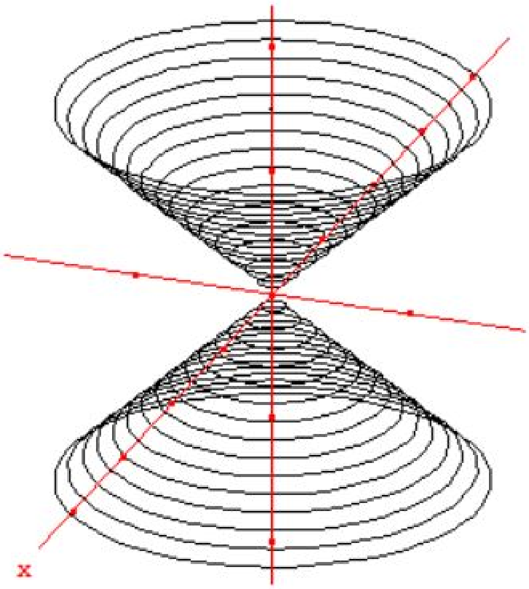

Figure 8.191: **Hyperbolic Circles Surface**

✍**Example:**

With Maple™ 4.00b a hyperboloid with $a=2, b=2, c=3$:

```
>with(plots):
>a:=2,b:=2,c:=3:
>plot3d(>implicitplot3d(x^2/a^2+y^2/b^2-z^2/c^2-1,x=-4..4,y=-4..4,
z=-4..4,orientation=[50,60],style=PATCH,axes=NORMAL);
```

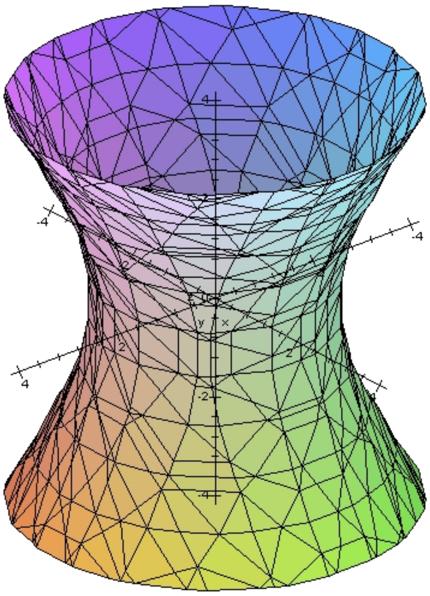

Figure 8.192: Parametric representation of a hyperboloid of one sheet in Maple™ 4.00b

Consider the case the equation $Ax^2+By^2+Cz^2=D$. Assume that $D>0$. Therefore:

- If two coefficients are positive and one is negative we speak of : "hyperboloid of one sheet".

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=1 \tag{8.5.317}$$

- If two coefficients are negative and one is positive we speak of: "hyperboloid of two sheets

$$-\frac{x^2}{a^2}-\frac{y^2}{b^2}+\frac{z^2}{c^2}=1 \tag{8.5.318}$$

W will meet the latter case during our study of the Michelson interferometer.

Here is also a very interesting figure that highlights the difference between a one sheet and two sheets hyperboloids:

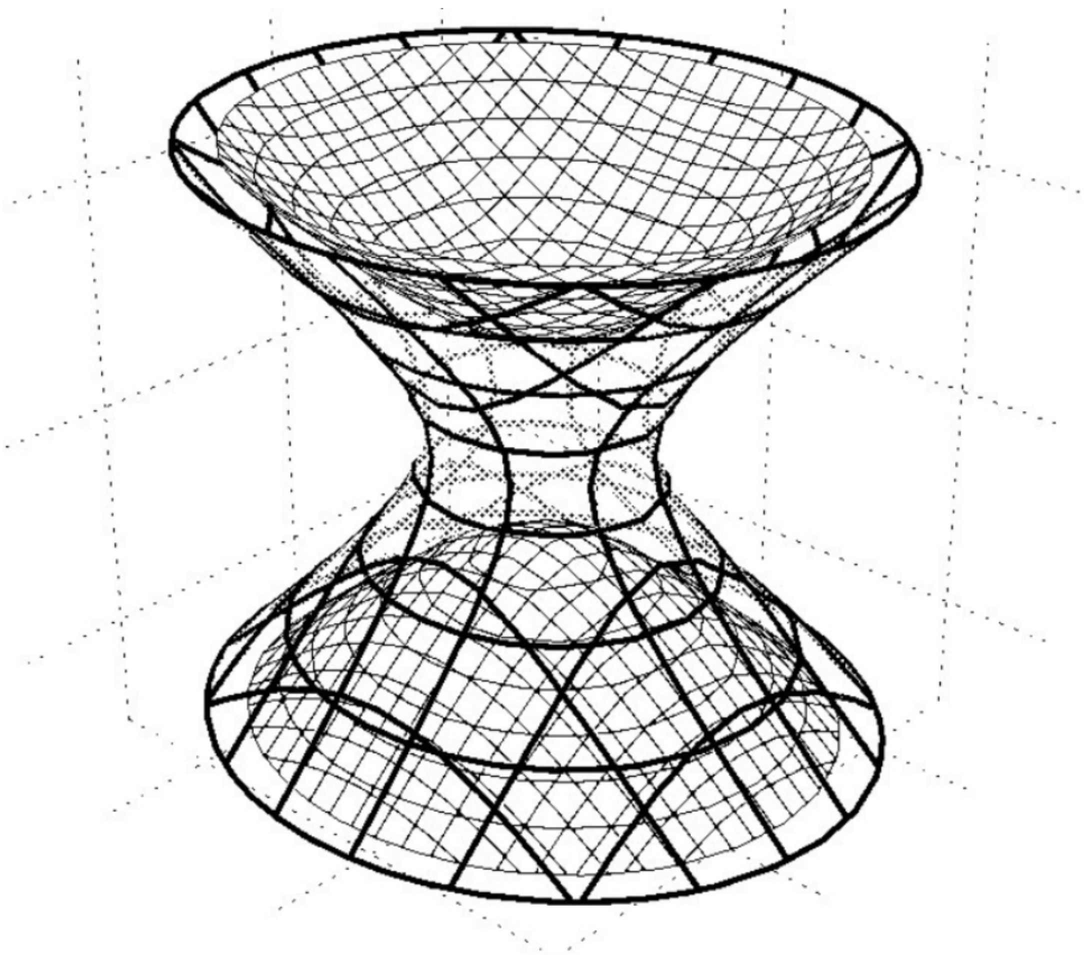

Figure 8.193: Two hyperboloids (of one sheet and two sheets) which are asymptotic to an identical elliptic cone

There are many other parametrizations, of the hyperboloid and so no such thing as the parametrization.

We have $x^2+y^2+1=z^2$. If we write $x^2+y^2=r^2$ (so we can take $x=r\cos(v)$, $y=r\sin(v)$), then $r^2+1=z^2$. Now since $\cosh^2(u)-\sinh^2(u)=1$, we could take $z=\cosh(u), r=\sinh(u)$, and thus:

$$\begin{aligned} x &= \sinh(u)\cos(v) \\ y &= \sinh(u)\sin(v) \\ z &= \cosh(u) \end{aligned} \tag{8.5.319}$$

However, this is not a good parametrization at $u=0$ (corresponding to the single point $(x,y,z)=(0,0,1)$.

Now let's try a different way. Write the equation as $t^2-y^2=1$ where $t^2=z^2-x^2$. We can take $y=\sinh(v)$ (note that this ranges over $\mathbb{R}$ as v does), and then $t^2=\cosh^2(v)$. If we choose the positive t (and we can), we have $t=\cosh(v)$. Now $(z/t)^2-(x/t)^2=1$. For the sheet with $z>0$ we can take $z/t=\cosh(u)$ and $x/t=\sinh(u)$. As u ranges over $\mathbb{R}$, we get all possible (x,z) pairs with $z>0$. So we have:

$$\begin{aligned} x &= \sinh(u)\cosh(v) \\ y &= \sinh(v) \\ z &= \cosh(u)\cosh(v) \end{aligned} \tag{8.5.320}$$

This parametrization is better because it maps $\mathbb{R}^2$ one-to-one onto one sheet.

We would like to share now a very nice and interesting (instructive) summary of most well known conical surfaces that we have studied so far and provided by OpenStax:

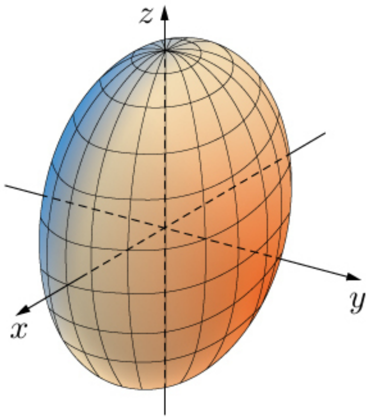
Ellipsoid

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$$

Traces:

- In plane $z=p$: an ellipse
- In plane $y=q$: an ellipse
- In plane $x=r$: an ellipse

If $a=b=c$ then this surface is sphere.



Hyperboloid of One Sheet

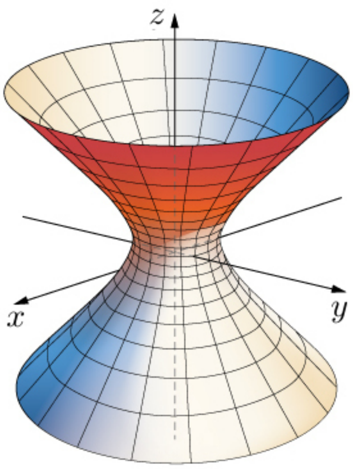
$$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=1$$

Traces:

- In plane $z=p$: an ellipse
- In plane $y=q$: a hyperbola
- In plane $x=r$: a hyperbola

In the equation for this surface, two of the variables have positive coefficients and one has negative coefficient.

The axis of the surface corresponds to the variable with the negative coefficient.



Hyperboloid of Two Sheets

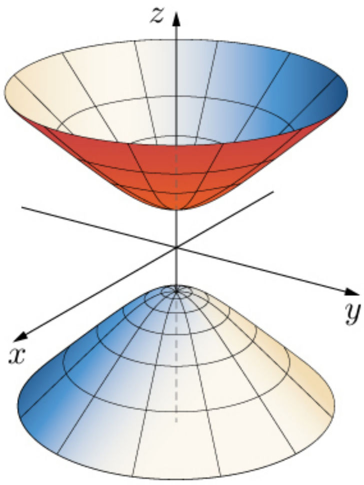
$$-\frac{x^2}{a^2}-\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$$

Traces:

- In plane $z=p$: an ellipse or the empty set (no trace)
- In plane $y=q$: a hyperbola
- In plane $x=r$: a hyperbola

In the equation for this surface, two of the variables have negative coefficients and one has positive coefficient.

The axis of the surface corresponds to the variable with a positive coefficient. The surface does not intersect the coordinate plane perpendicular to the axis.



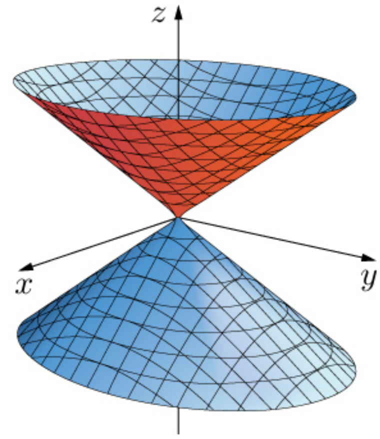
Elliptic Cone

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=0$$

Traces:

- In plane $z=p$: an ellipse
- In plane $y=q$: a hyperbola
- In plane $x=r$: a hyperbola
- In the xy-plane: a pair of lines that intersect at the origin
- In the yz-plane: a paire of lines that intersect at the origin

The axis of the surface corresponds to the variable with a negative coefficient. The traces in the coordinate planes parallel to the axis are intersecting lines.



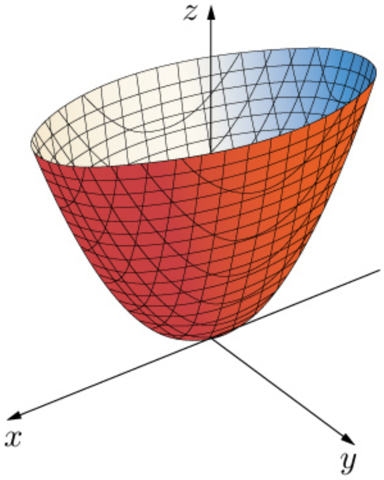
Elliptic Paraboloid

$$z=\frac{x^2}{a^2}+\frac{y^2}{b^2}$$

Traces:

- In plane $z=p$: an ellipse
- In plane $y=q$: a parabola
- In plane $x=r$: a parabola

The axis of the surface corresponds to the linear variable.



Hyperbolic Paraboloid

$$z=\frac{x^2}{a^2}-\frac{y^2}{b^2}$$

Traces:

- In plane $z=p$: a hyperbola
- In plane $y=q$: a parabola
- In plane $x=r$: a parabola

The axis of the surface corresponds to the linear variable.

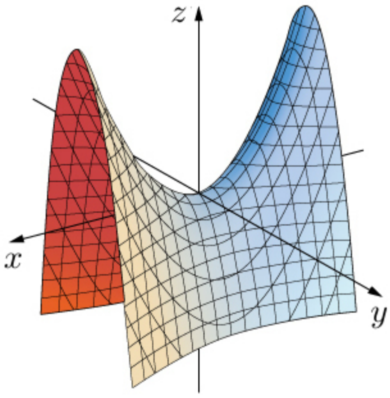


Figure 8.194: Common conical surfaces (source: OpenStax)

8.5.2.10.7 Torus

Definition (#8.5.360): In geometry, a "torus" is a surface of revolution generated by revolving a circle in three-dimensional space about an axis coplanar with the circle. If the axis of revolution does not touch the circle, the surface has a ring shape and is named a "torus of revolution".

We know that to generate a circle in the plane $x\text{O}y$, a possible parametric equation is:

$$x = r\cos(\phi) \qquad (8.5.321)$$

$$y = r\sin(\phi) \qquad (8.5.322)$$

To offset this circle to the right (in the direction of the positive x), we'll just add a strictly positive constant term x:

$$\begin{aligned} x &= a + r\cos(\phi) \\ y &= r\sin(\phi) \end{aligned} \qquad (8.5.323)$$

In space to draw a shifted circle in the $x\text{O}z$-plane we have therefore:

$$\begin{aligned} x &= a + r\cos(\phi) \\ z &= r\sin(\phi) \end{aligned} \qquad (8.5.324)$$

Which traditional notation is in the context of the study of torus:

$$\begin{aligned} x &= R + r\cos(\phi) \\ z &= r\sin(\phi) \end{aligned} \qquad (8.5.325)$$

If we want to generate a torus, we will rotate the circle around the u-axis by making it following a circle in the plane $x\text{O}y$. We then have the "parametric equation of the torus of revolution":

$$\boxed{\begin{pmatrix} x(\phi,\theta) \\ y(\phi,\theta) \\ z(\phi) \end{pmatrix} = \begin{pmatrix} (R + r\cos(\phi))\cos(\theta) \\ (R + r\cos(\phi)\sin(\theta) \\ r\sin(\phi) \end{pmatrix}} \qquad (8.5.326)$$

✍**Example:**

With Maple™ 4.00b a torus with $r = 1, R = 4$:

```
>r:=1:R:=4
>plot3d([(R+r*cos(phi))*cos(theta),(R+r*cos(phi))*sin(theta),
1*sin(phi)],
theta=-Pi..Pi,phi=-Pi..Pi,scaling=CONSTRAINED,orientation=[50,60],
style=PATCH,axes=NORMAL);
```

8.6. Differential Geometry

As we have already mentioned it in the section of Non-Euclidean geometry, differential geometry is the branch of geometry that aims to study the local and intrinsic properties (in the neighbourhood of a point) of curves and non-Euclidean surfaces (as a generalization of Euclidean surfaces!).

Differential geometry takes its name from the fact that it was born from the possibility of a kinematic interpretation that infinitesimal calculus brings to the study of curves. The points that we will discuss here will also serve well in the study of classical mechanics as complex analysis applied to many areas of study physical fields.

Remark

Before we tackle the very formal and abstract manner to address differential geometry with the tools of Topology (usual method used by mathematicians) we have chose in a first time to present the essential elements in the most simple and enjoyable as this is done in some engineering schools. Purists will therefore perhaps excuse us... or wait for something better...

8.6.1 Parametric Curves

Definition (#8.6.361): We will assimilate the "physical space" to $\mathbb{R}^3$ and will suppose that it includes a referential $R=(\mathrm{O},\vec{i},\vec{j},\vec{k})$ and we will denote by B the base $(\vec{i},\vec{j},\vec{k})$.

Let us consider a set $I\subset\mathbb{R}$ and a function $\Gamma=f(I)$ such that:

$$f\begin{pmatrix} I\rightarrow\mathbb{R}^3 \\ t\rightarrow f(t)=M \end{pmatrix},M(x,y,z)_R \tag{8.6.1}$$

that is a parametric equations that defines a group of quantities as functions of one or more independent "parameters".

Parametric curves are commonly used in kinematics, where the trajectory of an object is represented by equations depending on time as the parameter. Because of this application, a single parameter is often labelled t. However, parameters can represent other physical quantities (such as geometric variables) or can be selected arbitrarily for convenience.

Remarks

R1. If f is continuous, then Γ is a curve in space named "curve in one piece".

R2. A parabola, a sinusoid are curves named "flat curves". An ellipse, a circle are named "closed planar curves". For these examples, all points of the considered curves are located in a same plane. Conversely, a curve is named "left curve" if it is not so.

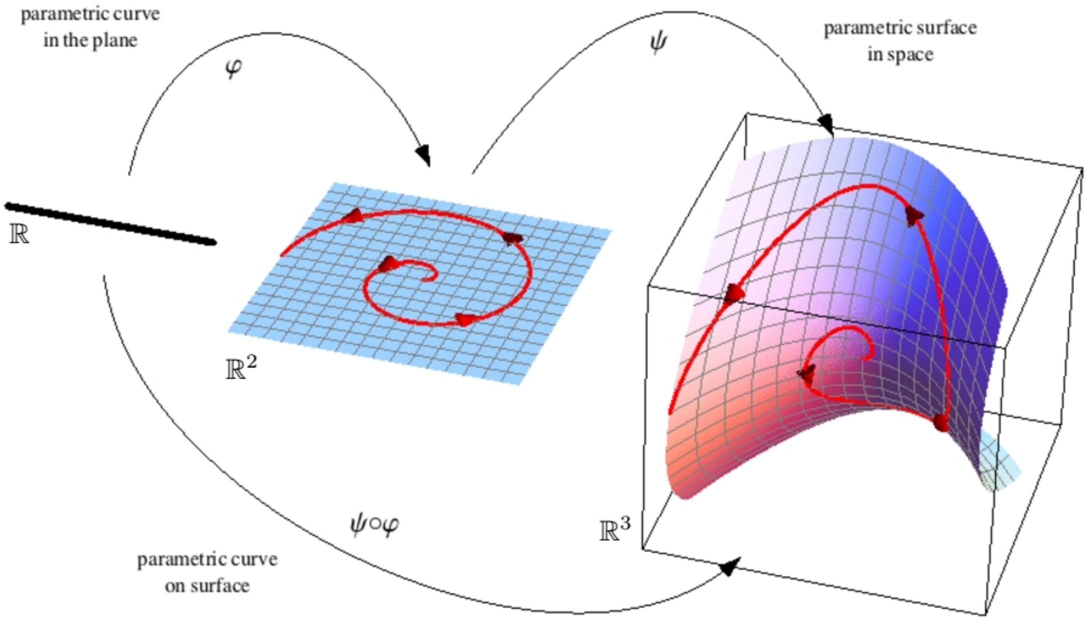

Figure 8.196: **Parametric curve and parametric surface**

Let us choose $t_0 \in I$ and put $M_0 = f(t_0)$ which we will denote by $M(t_0)$ then we can state the following definition: the pair (f, I) where f is a continuous function is named "parametric arc". Γ is named the "support" of (f, I) and t_0 is an "origin" of (f, I).

Note that parametric representations are generally non-unique, so the same quantities may be expressed by a number of different parametrizations.

Remarks

R1. Abusively, and more frequently, we also say that (f, I) is a "parametrization" of Γ.

R2. It is easy to define other parametrized arcs admitting also Γ as support. To do this, it is sufficient to give us a bijective function φ of I to $J \subset \mathbb{R}$ and such that $f(t) = f(\varphi^{-1}(x))$.

Before continuing, remember that in differential geometry, the "curvilinear abscissa" or "line-element" is a kind of algebraic variation of the length of an arc (this is therefore the analogous, on a curve, of the abscissa on a straight oriented line).

Let us consider now the following curvilinear abscissa (see section Special Relativity page 5704):

$$\mathrm{d}s^2 = g_{ij}\mathrm{d}u^i\mathrm{d}u^j \tag{8.6.2}$$

we have already seen that in a canonical Euclidean space (in $\mathbb{R}^n$) the curvilinear abscissa is then written:

$$\mathrm{d}s^2 = \delta_{ij}\mathrm{d}u^i\mathrm{d}u^j \tag{8.6.3}$$

with $i,j=1,2,3$ and as we have $\delta_{ij}=0, i\neq j$, it remains in $\mathbb{R}^3$:

$$\mathrm{d}s^2=\mathrm{d}u^1\mathrm{d}u^1+\mathrm{d}u^2\mathrm{d}u^2+\mathrm{d}u^3\mathrm{d}u^3=(\mathrm{d}u^1)^2+(\mathrm{d}u^2)^2+(\mathrm{d}u^3)^2 \tag{8.6.4}$$

In the Cartesian system:

$$u^1=x, u^2=y, u^3=z \tag{8.6.5}$$

so it comes:

$$\boxed{\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2} \tag{8.6.6}$$

which is therefore the linear differential element of an Euclidean space (the shortest path or the "geodesic" or "differential curvilinear abscissa") that we have already met many times in various section of this textbook. So this is nothing new or surprising!

If we restrict ourselves to the plane, the differential curvilinear abscissa of a plane curve is then obviously:

$$\boxed{\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2} \tag{8.6.7}$$

We already know how to use this equation (we used it in the section of Analytical Mechanics). But as a reminder never hurts, let us do examples with a straight line, a parabola and a half-circle (the choice is not innocent!).

✍**Examples:**

E1. Consider the general equation of a line in the plane (it's not a plane curve for reminder but a straight flat line!):

$$y=ax+b \tag{8.6.8}$$

It then comes immediately:

$$\mathrm{d}y=a\mathrm{d}x \tag{8.6.9}$$

Therefore:

$$\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2=\mathrm{d}x^2+(a\mathrm{d}x)^2=(1+a^2)\mathrm{d}x^2 \tag{8.6.10}$$

E2. Consider now the following equation of a parabola in the plane:

$$y=ax^2+b \tag{8.6.11}$$

It then comes immediately:

$$\mathrm{d}y=2ax\mathrm{d}x \tag{8.6.12}$$

Therefore:

$$\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2=\mathrm{d}x^2+(2ax\mathrm{d}x)^2=(1+4a^2x^2)\mathrm{d}x^2 \tag{8.6.13}$$

E3. Consider the equation of an ellipse (see section Analytical Geometry page 2768) written as:

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=R^2 \tag{8.6.14}$$

after rearrangement:

$$y=\sqrt{b^2\left(R-\frac{x^2}{a^2}\right)}=\sqrt{b^2R-b^2\frac{x^2}{a^2}} \tag{8.6.15}$$

It then comes immediately:

$$\mathrm{d}y=-\frac{b^2}{a^2\sqrt{b^2R-b^2\dfrac{x^2}{a^2}}}x\mathrm{d}x \tag{8.6.16}$$

Hence:

$$\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2=\mathrm{d}x^2+\left(-\frac{b^2}{a^2\sqrt{b^2R-b^2\dfrac{x^2}{a^2}}}x\mathrm{d}x\right)^2=\left(1+\frac{b^2}{a^4R-a^2x^2}x^2\right)\mathrm{d}x^2 \tag{8.6.17}$$

Notice that by making a Maclaurin approximation (when x is therefore zero, which corresponds to the study of the pole of the ellipse) we get (see section Sequences and Series page 1703):

$$y=\sqrt{b^2\left(R^2-\frac{x^2}{a^2}\right)}\cong\sqrt{b^2R}-\frac{1}{2}\frac{\sqrt{b^2R}}{a^2R}x^2 \tag{8.6.18}$$

Following the request of a reader here are the details of the development of the previous result. First recall the Taylor series (see section Sequences and Series page 1696):

$$f(x)\cong f(x_0)+\frac{1}{1!}f'(x_0)(x-x_0)+\frac{1}{2!}f''(x_0)(x-x_0)^2+\ldots \tag{8.6.19}$$

If we put $x_0=0$, we get the Maclaurin series:

$$f(x)\cong f(0)+\frac{1}{1!}f'(0)x+\frac{1}{2!}f''(0)x^2+\ldots \tag{8.6.20}$$

Therefore we get proceeding in two stages:

$$\begin{aligned}
y \cong\ & \frac{\mathrm{d}}{\mathrm{d}x^0}\sqrt{b^2\left(R^2-\frac{x^2}{a^2}\right)}\Bigg|_{x=x_0}(x-x_0)^0+\frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}x^1}\sqrt{b^2\left(R^2-\frac{x^2}{a^2}\right)}\Bigg|_{x=x_0}(x-x_0)^1\\
&+\frac{1}{2!}\frac{\mathrm{d}}{\mathrm{d}x^2}\sqrt{b^2\left(R^2-\frac{x^2}{a^2}\right)}\Bigg|_{x=x_0}(x-x_0)^2\\
&=\sqrt{b^2\left(R^2-\frac{x_0^2}{a^2}\right)}+\frac{1}{1}\frac{\mathrm{d}}{\mathrm{d}x}\sqrt{b^2\left(R^2-\frac{x^2}{a^2}\right)}\Bigg|_{x=x_0}(x-x_0)\\
&+\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}x^2}\sqrt{b^2\left(R^2-\frac{x^2}{a^2}\right)}\Bigg|_{x=x_0}(x-x_0)^2\\
&=\sqrt{b^2\left(R^2-\frac{x_0^2}{a^2}\right)}+\frac{-\dfrac{b^2x}{a^2}}{\sqrt{b^2\left(R^2-\dfrac{x_0^2}{a^2}\right)}}\Bigg|_{x=x_0}(x-x_0)\\
&+\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}x}\frac{-\dfrac{b^2x}{a^2}}{\sqrt{b^2\left(R^2-\dfrac{x^2}{a^2}\right)}}\Bigg|_{x=x_0}(x-x_0)^2
\end{aligned}\tag{8.6.21}$$

$$\begin{aligned}
&=\sqrt{b^2\left(R^2-\frac{x_0^2}{a^2}\right)}+\frac{-\dfrac{b^2x_0}{a^2}}{\sqrt{b^2\left(R^2-\dfrac{x_0^2}{a^2}\right)}}(x-x_0)\\
&+\frac{1}{2}\left(\frac{-\dfrac{b^2}{a^2}}{\sqrt{b^2\left(R^2-\dfrac{x^2}{a^2}\right)}}+-\frac{2b^2}{a^2}x\cdot\ldots\right)\Bigg|_{x=x_0}(x-x_0)^2\\
&=\sqrt{b^2\left(R^2-\frac{x_0^2}{a^2}\right)}+\frac{-\dfrac{b^2x_0}{a^2}}{\sqrt{b^2\left(R^2-\dfrac{x_0^2}{a^2}\right)}}(x-x_0)\\
&+\frac{1}{2}\left(\frac{-\dfrac{b^2}{a^2}}{\sqrt{b^2\left(R^2-\dfrac{x_0^2}{a^2}\right)}}+-\frac{2b^2}{a^2}x_0\cdot\ldots\right)(x-x_0)^2
\end{aligned}\tag{8.6.22}$$

by putting $x_0=0$ we get:

$$\begin{aligned}
y &\cong \sqrt{b^2R}+0\cdot x+\frac{1}{2}\left(\frac{-\dfrac{b^2}{a^2}}{\sqrt{b^2\left(R^2-\dfrac{0^2}{a^2}\right)}}+-\frac{2b^2}{a^2}0\cdot\ldots\right)x^2\\
&=\sqrt{b^2R}+\frac{1}{2}\frac{-\dfrac{b^2}{a^2}}{\sqrt{b^2R}}x^2=\sqrt{b^2R}-\frac{1}{2}\frac{b^2}{a^2\sqrt{b^2R}}x^2=\sqrt{b^2R}-\frac{1}{2}\frac{\sqrt{b^2R}}{\sqrt{b^2R}}\frac{b^2}{a^2\sqrt{b^2R}}x^2\\
&=\sqrt{b^2R}-\frac{1}{2}\frac{\sqrt{b^2R}}{a^2R}x^2
\end{aligned}\tag{8.6.23}$$

It then comes immediately:

$$\mathrm{d}y=-\frac{\sqrt{b^2R}}{a^2R}x\mathrm{d}x\tag{8.6.24}$$

Therefore:

$$\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2=\mathrm{d}x^2+\left(-\frac{\sqrt{b^2R}}{a^2R}x\mathrm{d}x\right)^2=\left(1+\frac{b^2}{a^4R}x^2\right)\mathrm{d}x^2\tag{8.6.25}$$

We see then that the curvilinear abscissa of an ellipse in the plane becomes that of a parabola when we make a Maclaurin series expansion of the equation of the ellipse at the pole.

We could do the same with an hyperbole and end up with the same form of differential curvilinear abscissa, usually denoted by tradition:

$$\boxed{\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2=\left(1+k_x^2x^2\right)\mathrm{d}x^2}\tag{8.6.26}$$

where k_x is named the "osculator parameter of the parabola".

What is veeery important to notice with the developments above (we can do it also identically for the hyperbola that is just the elliptic case with a different sign on readers request) is that we finally have (remember that the ellipse is a general case of the sphere!):

$$\begin{aligned}
\mathrm{d}s_{\text{plane}}^2&=(1+a^2)\mathrm{d}x^2\\
\mathrm{d}s_{\text{parabole}}^2&=(1+4a^2x^2)\mathrm{d}x^2\\
\mathrm{d}s_{\text{ellipse}}^2&=(1+k_x^2x^2)\mathrm{d}x^2\\
\mathrm{d}s_{\text{hyperbola}}^2&=(1-k_x^2x^2)\mathrm{d}x^2
\end{aligned}\tag{8.6.27}$$

Where the last three cases are generally denoted:

$$\boxed{\mathrm{d}s=(1+K^2x^2)\mathrm{d}x^2}\tag{8.6.28}$$

We then understand better why many books on General Relativity or Differential Geometry say that:

- When $K=0$ all case reduce to a flat space
- When $K=+1$ (or more generally just positive) we are in a spherical space (in fact it's ellipsoidal)
- When $K=-1$ (or more generally just negative) we are in a hyperbolic space

These examples being closed, let us continue with the theory. We can obviously rewrite our differential curvilinear abscissa by dividing both sides of equality by $\mathrm{d}t$ as:

$$\boxed{\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^2=\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2+\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2+\left(\frac{\mathrm{d}z}{\mathrm{d}t}\right)^2} \tag{8.6.29}$$

Hence we get the famous relation:

$$\mathrm{d}s=\sqrt{\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2+\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2+\left(\frac{\mathrm{d}z}{\mathrm{d}t}\right)^2}\,\mathrm{d}t \tag{8.6.30}$$

✍**Example:**

Let us see an application of the parametrized differential curvilinear abscissa with an helix (the examples are pretty in differential geometry and therefore nice to see...) which is a typical left curve:

Let $t,r,h\in\mathbb{R}^3,t>0,r>,h>0$ and the function:

$$f(t):\begin{cases}[0,t]\mapsto\mathbb{R}^3\\ t\rightarrow f(t)=M\end{cases} \tag{8.6.31}$$

with $M(x,y,z)$ and parametric coordinates:

$$\begin{pmatrix}x\\y\\z\end{pmatrix}=\begin{pmatrix}r\cos(t)\\r\sin(t)\\ht\end{pmatrix} \tag{8.6.32}$$

We then have with Maple™ 4.00b by taking r and h as equal to 1:

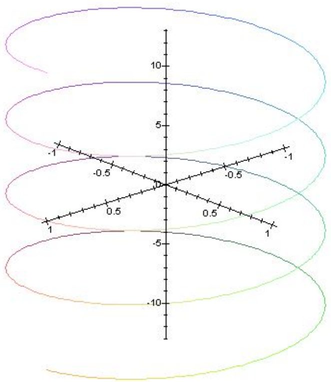

Figure 8.197: **Parametric representation of an helix in Maple™ 4.00b**

The function f is a parametric arc whose support is named an "helix", r is the radius and h is the step. Taking $t_0 = 0$ as the origin, the curvilinear abscissa of this helix (one piece) is given by:

$$\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^2 = \left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2 + \left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2 + \left(\frac{\mathrm{d}z}{\mathrm{d}t}\right)^2 = r^2\sin^2(t) + r^2\cos^2(t) + h^2 = r^2 + h^2 \tag{8.6.33}$$

Therefore:

$$\frac{\mathrm{d}s}{\mathrm{d}t} = \sqrt{r^2 + h^2} \tag{8.6.34}$$

and hence by integration:

$$s = \sqrt{r^2 + h^2}t \tag{8.6.35}$$

8.6.2 Isolines

Let us see now a very important point in mathematics but also in medical engineering, astrophysics, meteorology (among many other areas) that are isolines.

Before addressing the subject in a purely mathematical form, we suggest the reader to open MATLAB® 5.0.0.473 (we've done also pretty much the same example with Maple™ 4.00b in the section of Functional Analysis) and write in it:

```
»[xx,yy,z]=peaks;
»figure(1);mesh(xx,yy,z);title('peaks')
```

We get:

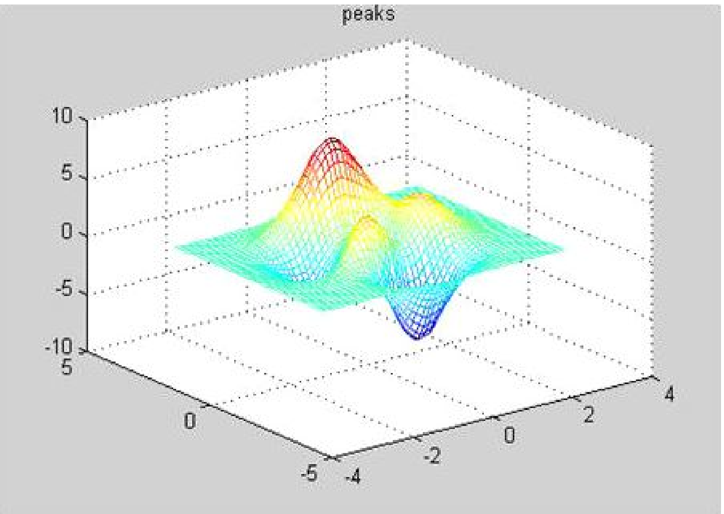

Figure 8.198: **Initial plot in MATLAB® 5.0.0.473**

then for aesthetic reasons, to write:

```
»figure(2);surf(xx,yy,z);title('surf')
```

We get:

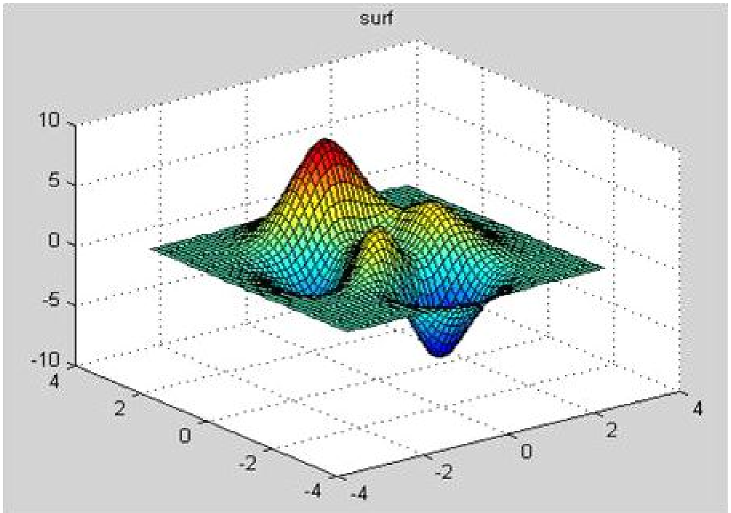

Figure 8.199: Plot rendering modification in MATLAB® 5.0.0.473

Then we would like MATLAB® to plot for us some level curves (the points where the value of the function $f(x, y)$ is constant), named by the mathematicians "isolines" or "iso-level curves". For this we must write:

```
»figure(3);contour3(xx,yy,z);title('contour')
```

We get:

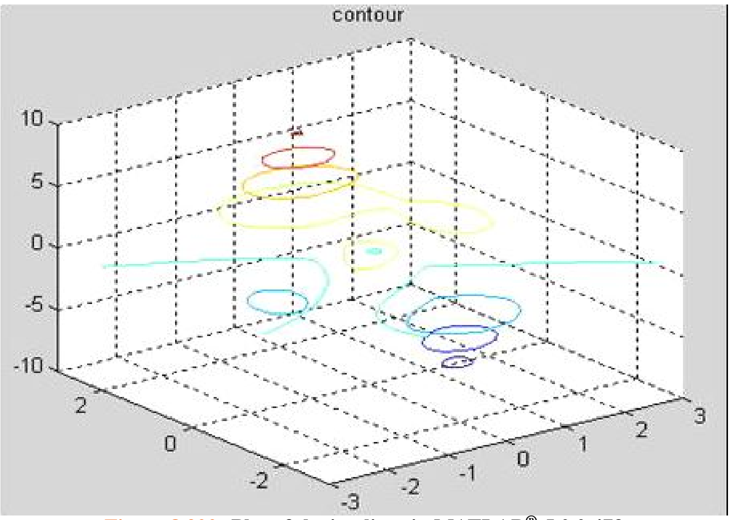

Figure 8.200: Plot of the isoclines in MATLAB® 5.0.0.473

We will then ask the software to project the isoclines on the X, Y plane. This is done with:

```
»figure(3);contour(xx,yy,z);title('contour')
```

We get:

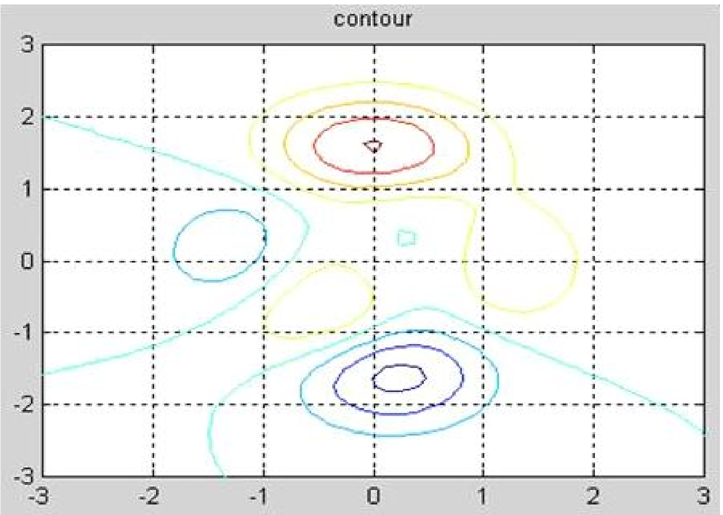

Figure 8.201: **Projection of the isoclines in MATLAB® 5.0.0.473**

And it is these curves that will interest us. We would like to determine the algebraic expression in the plane of the latter. But first let's have fun with MATLAB® by writing again:

```
»figure(3);contour(xx,yy,z);title('contour')
```

We get:

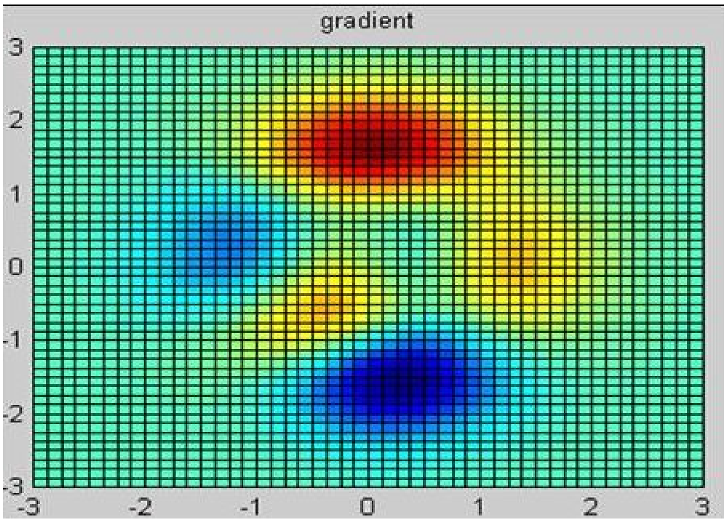

Figure 8.202: **Plane representation of isoclines with coloured gradients in MATLAB® 5.0.0.473**

but we can do even better by removing the grid with the command:

```
»shading interp
```

We get:

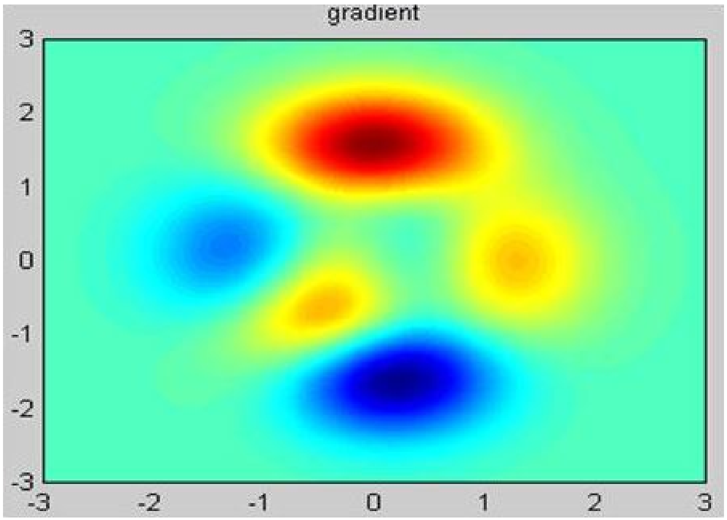

Figure 8.203: **Plane representation of isoclines with coloured gradients and without grid in MATLAB® 5.0.0.473**

Then, without closing the above now add the line:

```
»hold on; contour(xx,yy,z,'k')
```

We get:

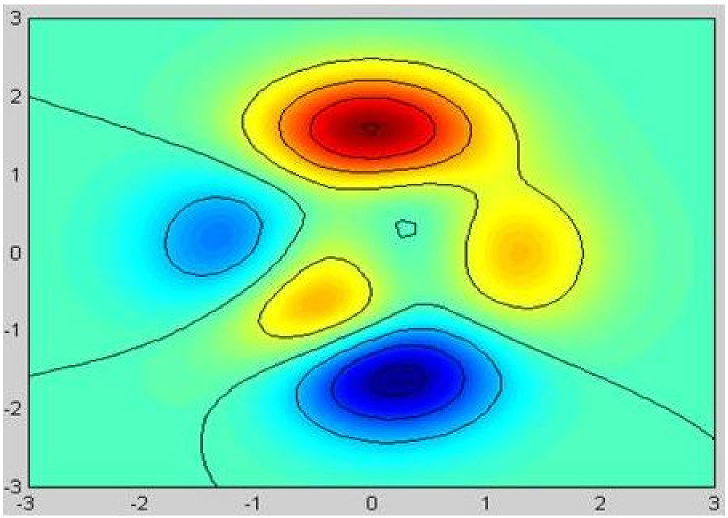

Figure 8.204: **Isoclines association projected with color gradients in MATLAB® 5.0.0.473**

Definition (#8.6.362): In mathematics, a level set of a real-valued function f of n real variables is a set of the form:

$$L_c(f)=\{(x_1,\cdots,x_n)\mid f(x_1,\cdots,x_n)=c^{te}\} \tag{8.6.36}$$

that is, a set where the function takes on a given constant value c^{te}.

When the number of variables is two, a level set is generically a curve, named a "level curve", "contour line", or "isoline". So a level curve is the set of all real-valued solutions of an equation in two variables x_1 and x_2. When $n=3$, a level set is named a "level surface" or "isosurface", and for higher values of n the level set is a named a "hypersurface". So a "level surface" is the set of all real-valued roots of an equation in three variables x_1, x_2 and x_3, and a "level hypersurface" is the set of all real-valued roots of an equation in $n\ (n>3)$ variables.

Let us now consider to determine the equation of the isolines the bivariate function $f(x,y)$ function and that we will impose as being $\mathbb{R}^2$-differentiable.

The relation:

$$f(x,y)=c^{te} \tag{8.6.37}$$

defines a plan curve Γ therefore named "isocline". It is a curve such that when x varies, then y will thus not vary such that f remains constant.

We saw in the section of Differential and Integral Calculus that the differential of f, for any infinitesimal variations of x and y is:

$$\mathrm{d}f=\frac{\partial f}{\partial x}\mathrm{d}x+\frac{\partial f}{\partial y}\mathrm{d}y \tag{8.6.38}$$

Now, if we want when x varies of $\mathrm{d}x$, the value of the function f does not change, $\mathrm{d}y$ must not be anything but such that the variation of $\mathrm{d}f$ is zero. In other words:

$$\mathrm{d}f=\frac{\partial f}{\partial x}\mathrm{d}x+\frac{\partial f}{\partial y}\mathrm{d}y=0 \tag{8.6.39}$$

along Γ. But this equation is useless as such, but it fixed us the ratio of the derivative of the isoline in the plane such as:

$$\frac{\mathrm{d}y}{\mathrm{d}x}=-\frac{\dfrac{\partial f}{\partial x}}{\dfrac{\partial f}{\partial y}} \tag{8.6.40}$$

which gives us the slope of the tangent to Γ and thus after by integration, the desired function itself!!!

It goes without saying that the tangent vector to the curve Γ is a vector parallel to the one whose having for components (by correspondence with the above relation):

$$(\mathrm{d}x,\mathrm{d}y)=\left(\frac{\partial f}{\partial y},-\frac{\partial f}{\partial x}\right) \tag{8.6.41}$$

that we will denote by:

$$\vec{t}=\left(\frac{\partial f}{\partial y},-\frac{\partial f}{\partial x}\right) \tag{8.6.42}$$

Also recall that the gradient is given by (see section Vector Calculus page 1869):

$$\vec{\nabla}(f)=\left(\frac{\partial f}{\partial x},\frac{\partial f}{\partial y}\right) \tag{8.6.43}$$

We note that the latter two vectors are perpendicular (result which will be very useful in the section of Complex Analysis). Indeed, calculating the dot product (see section Vector Calculus page 1821):

$$\vec{t}\circ\vec{\nabla}(f)=\left(\frac{\partial f}{\partial y},-\frac{\partial f}{\partial x}\right)\circ\left(\frac{\partial f}{\partial x},\frac{\partial f}{\partial y}\right)=\frac{\partial f}{\partial x}\frac{\partial f}{\partial y}+\left(-\frac{\partial f}{\partial y}\right)\frac{\partial f}{\partial x}=0 \quad (8.6.44)$$

In other words, the vector $\vec{\nabla}(f)$ defines the orthogonal lines to the curve Γ.

✍**Example:**

Consider the equation of a special parabola in $\mathbb{R}^3$:

$$f(z)=\sqrt{x^2+y^2} \quad (8.6.45)$$

So we have the isoclines which are given by:

$$f(z)=\sqrt{x^2+y^2}=c^{te} \quad (8.6.46)$$

hence their equation in the plane:

$$y=\sqrt{c^{te}-x^2} \quad (8.6.47)$$

That is to say circles in the plane whose radius is equal to the square root of the corresponding selected constant at the height z height of f!

Let us now calculate the slope of the tangent Γ to these circles:

$$\frac{\mathrm{d}y}{\mathrm{d}x}=-\frac{\dfrac{\partial f}{\partial x}}{\dfrac{\partial f}{\partial y}}=-\frac{\dfrac{x}{\sqrt{x^2+y^2}}}{\dfrac{y}{\sqrt{x^2+y^2}}}=-\frac{x}{y}=-\frac{x}{\sqrt{c^{te}-x^2}} \quad (8.6.48)$$

This is consistent with the simple derivative of:

$$\frac{\mathrm{d}y}{\mathrm{d}x}=\frac{\mathrm{d}}{\mathrm{d}x}\sqrt{c^{te}-x^2}=-\frac{x}{\sqrt{c^{te}-x^2}} \quad (8.6.49)$$

We also have:

$$\vec{t}=\left(\frac{y}{\sqrt{c^{te}-x^2}},-\frac{x}{\sqrt{c^{te}-x^2}}\right) \quad (8.6.50)$$

We see that on $x=0$ this vector is equal to:

$$\vec{t}=(1,0) \quad (8.6.51)$$

which is intuitively consistent with the vector tangent to the circle that we have at this point of the x-axis.

8.6.3 Frenet Frame

One of the most important tools used to analyse a curve is the Frenet frame, a moving frame that provides a coordinate system at each point of the curve that is "best adapted" to the curve near that point.

The Frenet frame is a tool for the study of the local behaviour of the curves. More precisely, it is a local coordinate system associated with a point describing a curve Γ. Its construction method is different depending on the ambient space is 2-dimensional (plane curve) or 3-dimensional (left curve).

The Frenet frame and the Frenet formulas (giving the derivatives vectors of this frame) give the opportunity to conduct in a systematic way calculations of curvature and twisting of left curves and to introduce interesting geometric concepts associated with curves.

Let us first consider a curve Γ with its curvilinear abscissa $s(t)$ and $M_0=s(t_0)$ its origin. We denote by definition:

$$\vec{T}=\frac{\mathrm{d}\vec{f}(t)}{\mathrm{d}s}=\frac{\vec{f}(t+\mathrm{d}t)-\vec{f}(t)}{\mathrm{d}s}=\frac{\mathrm{d}\overrightarrow{\mathrm{O}M}}{\mathrm{d}s} \tag{8.6.52}$$

the tangent to the parametrized curve Γ of parameter t near a point M with respect to a frame put on O with $\mathrm{d}s$ that is calculated as we have shown previously.

It is interesting to note that if t is interpreted as begin the time (don't forget that this textbook is mainly target for engineering application), then we get a tangential speed:

$$\vec{v}=\vec{T}\frac{\mathrm{d}s}{\mathrm{d}t}=\vec{T}\|\vec{v}\|=\vec{T}v=\frac{\mathrm{d}\vec{f}(t)}{\vec{d}t} \tag{8.6.53}$$

and thus the $\vec{T}$ vector is obviously directed in the direction of movement.

Moreover, by construction and definition of the curvilinear abscissa, we always have:

$$\|\vec{T}\|=\frac{\mathrm{d}\overrightarrow{\mathrm{O}M}}{|\mathrm{d}s|} \tag{8.6.54}$$

and therefore the tangent vector $\vec{T}$ to the point M is unitary (and not zero!).

Now, without knowing exactly for what it will be useful for us now, let us look closer to the vector:

$$\frac{\vec{T}}{\mathrm{d}s} \tag{8.6.55}$$

Knowing trivially from the foregoing that:

$$\|\vec{T}\|=\vec{T}\circ\vec{T}=1 \tag{8.6.56}$$

Then we have:

$$\frac{\mathrm{d}\left(\vec{T}\circ\vec{T}\right)}{\mathrm{d}s}=\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}\circ\vec{T}+\vec{T}\circ\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}=2\vec{T}\circ\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}=0 \tag{8.6.57}$$

therefore first $\mathrm{d}\vec{T}/\mathrm{d}s$ is a posteriori not unitary and $\vec{T}$ is perpendicular to it (results that will serve us several times afterwards so it must be remember!).

Therefore:

$$\vec{T}\circ\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}=0 \tag{8.6.58}$$

Let us put:

$$\vec{N}=\frac{\dfrac{\mathrm{d}\vec{T}}{\mathrm{d}s}}{\left\|\dfrac{\mathrm{d}\vec{T}}{\mathrm{d}s}\right\|} \tag{8.6.59}$$

Given the previous result, $\vec{N}$ is the perpendicular vector, named unitary "curvature vector" at $\vec{T}$ on M. We say that this couple of vector $\left(\vec{T},\mathrm{d}\vec{T}/\mathrm{d}s\right)$ is "direct orthonormal" and C is by definition the "curvature".

We can approach the "curvature", denoted C, in a geometrically way. Let us see how!

We know at this step of our study that on a point M_0 of a curve Γ (differentiable at least once on every point - that is to say of class $\mathcal{C}^1$), there is a non-zero vector $\vec{T}$ which is tangent.

In any neighbouring point M (of curvilinear abscissa s), the tangent vector $\vec{T}$ can be written in approximation:

$$\vec{T}(s)\cong\vec{T}+\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}\mathrm{d}s \tag{8.6.60}$$

if the curve is locally in the same plane (for now we are here studying the curvature and not the twisting of a curve)!

Two normal at M and M_0 thus intersecting in a point Ω, the following figure:

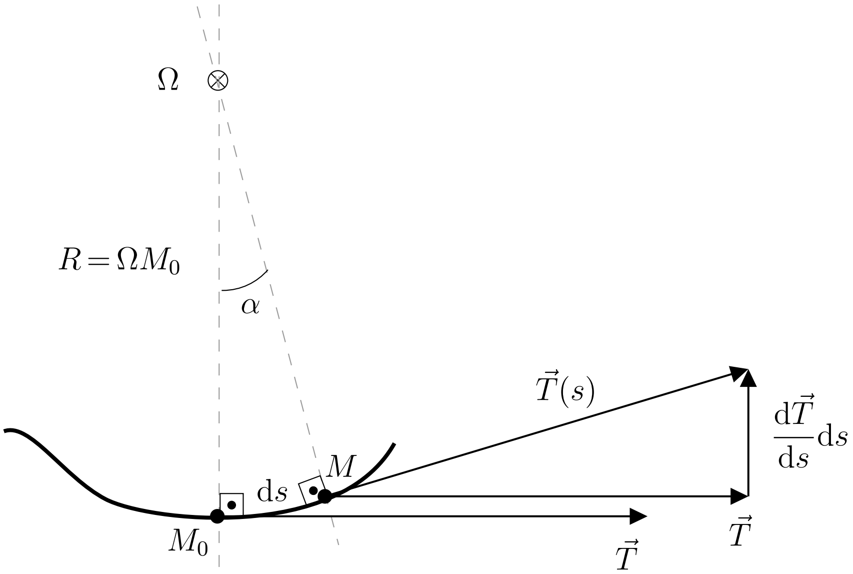

Figure 8.205: **Decomposition of the tangent vector of the curved path**

shows that at the first order in $\mathrm{d}s$, the point M can be considered locally as deduced from the point M_0 by a rotation of center Ω.

The circle thus defined of radius:

$$\overline{\Omega M_0} = R \tag{8.6.61}$$

is the one that best tangent the curve locally at the point M_0. Its radius is derived from the figure (two similar triangles at the limit):

$$\frac{\mathrm{d}s}{R} = \frac{\left\|\dfrac{\mathrm{d}\vec{T}}{\mathrm{d}s}\right\|\mathrm{d}s}{\|\vec{T}\|} \tag{8.6.62}$$

hence, since $\vec{T}$ is unitary, the definition of the value of the curvature for a plane curve:

$$\boxed{C = \frac{1}{R} = \left\|\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}\right\|} \tag{8.6.63}$$

and that's it!

It is possible to interpret the concept of curvature as the speed of rotation of the Frenet frame relatively to a fixed direction.

The pair of vectors $(\vec{T},\vec{N})$ is named a "Frenet frame" and the basis vectors the "Frenet vectors".

The Frenet frame is a moving frame and the elements of this frame change depending on the point in question. In physics, we must not confuse this with the repository: as Frenet vectors move with the point!

Remark

The definition of C as above is true in the context of a choice of positive curvature. It's taken in a mechanical point of view but not necessary in pure mathematics.

If $C \neq 0$, then as seen above we can now write:

$$\vec{N} = \frac{\dfrac{\mathrm{d}\vec{T}}{\mathrm{d}s}}{\left\|\dfrac{\mathrm{d}\vec{T}}{\mathrm{d}s}\right\|} = \frac{\dfrac{\mathrm{d}\vec{T}}{\mathrm{d}s}}{C} = \frac{1}{C}\frac{\mathrm{d}\vec{T}}{\mathrm{d}s} = R\frac{\mathrm{d}\vec{T}}{\mathrm{d}s} \tag{8.6.64}$$

where R is named the "curvature radius". Depending on the situation (i.e. position on the curve) $\|\vec{T}\|$ can be bigger or smaller than the curvature radius R!

About the relation:

$$\boxed{\frac{\vec{N}}{R} = \frac{\mathrm{d}\vec{T}}{\mathrm{d}s}} \tag{8.6.65}$$

is named the "first Frenet formula" and shows obviously that $\vec{N}$ and $\mathrm{d}\vec{T}/\mathrm{d}s$ are collinear and hence their cross product is zero (result that will be used later).

These relations are justified by the analogy with mechanics. Indeed, remember that we have shown above that:

$$\vec{v}=\vec{T}\frac{\mathrm{d}s}{\mathrm{d}t}=\vec{T}\|\vec{v}\|=\vec{T}v=\frac{\mathrm{d}\vec{f}(t)}{\vec{d}t} \qquad (8.6.66)$$

Let us now calculate the acceleration:

$$\begin{aligned}\vec{a}&=\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=\frac{\vec{T}v}{\mathrm{d}t}=v\frac{\mathrm{d}\vec{T}}{\mathrm{d}t}+\vec{T}\frac{\mathrm{d}v}{\mathrm{d}t}=v\frac{\mathrm{d}s}{\mathrm{d}t}\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}+\vec{T}\frac{\mathrm{d}v}{\mathrm{d}t}=v^2\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}+\vec{T}\frac{\mathrm{d}v}{\mathrm{d}t}\\&=v^2C\vec{N}+\vec{T}\frac{\mathrm{d}v}{\mathrm{d}t}=\vec{T}\frac{\mathrm{d}v}{\mathrm{d}t}+\frac{v^2}{R}\vec{N}=\vec{a}_{\text{tg}}+\vec{a}_n\end{aligned} \qquad (8.6.67)$$

we fall back on the result obtained in the section of Classical Mechanics in our study of the osculating plane (see page 3237).

Figure 8.206: **Tangential and Normal acceleration**

To give a more accurate geometric interpretation of the curvature, we define first through Ω the "center of curvature" of the "osculating circle" (placed in the osculating plane) or "curvature circle" of radius R that tangent locally the best the curve Γ in the Frenet frame:

$$\vec{\Omega}=\vec{M}+R\vec{N} \qquad (8.6.68)$$

To clarify geometrically what is the osculating circle, take a curve and a point M on that curve. Then draw the normal at this point of the locally plane curve equation and take a point Ω on the normal. Then, the center Ω of the circle passing through the point M is tangent to the curve. But all the circles tangent to the curve are not tangent in the same way! Indeed, if Ω is far from M, the circle will be located rather outside of the curve (blue and red circles in the figure below). If Ω is close to M, the circle will be located rather inside of the curve (yellow circle in the figure below). The limit radius between being "inside the curve" and being "outside the curve" is conventionally the "radius of curvature" we defined earlier above. The circle of that radius is then the famous "osculating circle"!

in green: the "best tangent circle" or "osculating circle" to the curve Γ

Figure 8.207: Representation of an osculating circle

In the particular case where $\vec{T}$ is a constant vector we have obviously:

$$\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}=\vec{0} \tag{8.6.69}$$

and therefore $C=0$ implying that R is no longer define. We sometimes say that in this case that the radius of curvature of Γ is infinite (a straight line then has a zero curvature at any point).

Let us now consider the vector perpendicular to the osculating plane defined and denoted by:

$$\vec{B}=\vec{T}\times\vec{N} \tag{8.6.70}$$

We can already say, since $\vec{T}$ and $\vec{N}$ are of unit norm that $\vec{B}$ is also of unit norm (which will serve us later)!

We can see that $\mathrm{d}\vec{B}/\mathrm{d}s$ is obviously orthogonal to $\vec{T}$. Indeed:

$$\frac{\mathrm{d}\vec{B}}{\mathrm{d}s}=\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}\times\vec{N}+\vec{T}\frac{\mathrm{d}\vec{N}}{\mathrm{d}s}=\vec{0}\times\vec{N}+\vec{T}\frac{\mathrm{d}\vec{N}}{\mathrm{d}s}=\vec{T}\frac{\mathrm{d}\vec{N}}{\mathrm{d}s} \tag{8.6.71}$$

where we took the special case $\mathrm{d}\vec{T}/\mathrm{d}s=\vec{0}$ (but anyway in general $\mathrm{d}\vec{T}/\mathrm{d}s$ and $\vec{N}$ are collinear as we have prove it earlier and therefore the cross product of these two vectors is always zero).

As $\mathrm{d}\vec{B}/\mathrm{d}s$ is perpendicular to $\vec{T}$ it is therefore collinear to $\vec{N}$.

Therefore, as $\mathrm{d}\vec{T}/\mathrm{d}s$ is perpendicular to $\vec{T}$, $\mathrm{d}\vec{B}/\mathrm{d}s$ is perpendicular $\vec{B}$. This can be proven using exactly the same trick as when we have proved that $\mathrm{d}\vec{T}/\mathrm{d}s$ is perpendicular to $\vec{T}$.

Therefore:

$$\vec{B}\circ\frac{\mathrm{d}\vec{B}}{\mathrm{d}s}=0 \tag{8.6.72}$$

Let us put:

$$\boxed{\frac{\mathrm{d}\vec{B}}{\mathrm{d}s}=\frac{\vec{N}}{R'}=\tau\vec{N}} \tag{8.6.73}$$

This relation is the "second Frenet formula" where by definition, $\vec{B}$ is the "bi-normal vector" of Γ at the point M and τ the "twist" and R' the "torsion radius".

We can now establish the third Frenet formula. For this we start from:

$$\vec{B}=\vec{T}\times\vec{N}\Leftrightarrow\vec{N}=\vec{B}\times\vec{T} \tag{8.6.74}$$

from which we get:

$$\frac{\mathrm{d}\vec{N}}{\mathrm{d}s}=\frac{\mathrm{d}\vec{B}}{\mathrm{d}s}\times\vec{T}+\vec{B}\times\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}=\frac{\vec{N}}{R'}\times\vec{T}+\vec{B}\times\frac{\vec{N}}{R} \tag{8.6.75}$$

But, by the properties of the cross product (see section Vector Calculus page 1830):

$$\vec{N}\times\vec{T}=-\vec{B}\qquad\vec{B}\times\vec{N}=-\vec{T} \tag{8.6.76}$$

hence the "third Frenet formula":

$$\boxed{\frac{\mathrm{d}\vec{N}}{\mathrm{d}s}=-\frac{\vec{B}}{R'}-\frac{\vec{T}}{R'}} \tag{8.6.77}$$

We name "Frenet trihedron" or "Frenet-Serret frame" associated to the curve Γ at point M, the natural orthonormal space frame $(M,\vec{T},\vec{N},\vec{B})$:

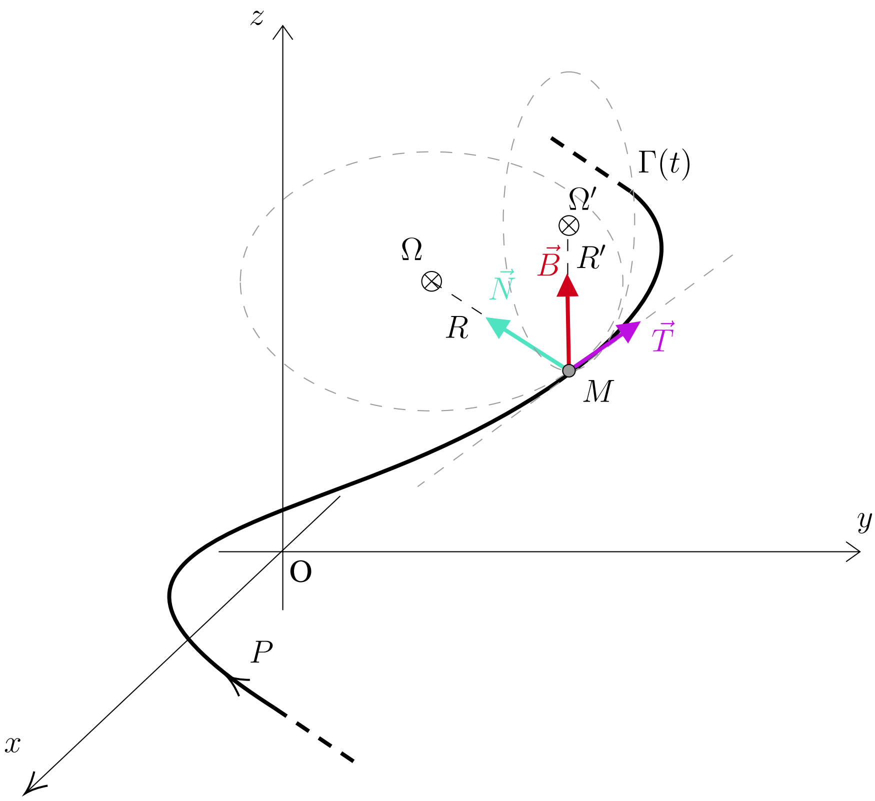

Figure 8.208: **Representation of the trihedron**

where, in mechanics, the vector $\vec{T}$ is collinear to the velocity and to tangential acceleration and $\vec{N}$ is collinear with the normal acceleration.

Remark

The radius of curvature R is in the osculating plane (the plane formed by the tangent and normal vector to the curve) which is the best plan in which is contained the curve. So, the radius of curvature gives in a point (locally) the best ("truest") radius of the curve. The twist gives us against the tendency of the curve of going out of the osculating plane (verbatim if the curve is contained in a plane, torsion is zero).

✍**Examples:**

E1. We consider the plane parametric equation of a parabola:

$$\Gamma(t)=\begin{pmatrix} t \\ t^2 \end{pmatrix} \tag{8.6.78}$$

Therefore we have:

$$\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^2=\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2+\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2=1+4t^2 \tag{8.6.79}$$

Hence:

$$\frac{\mathrm{d}s}{\mathrm{d}t}=\sqrt{1+4t^2} \tag{8.6.80}$$

Therefore we have:

$$\vec{T}=\frac{\mathrm{d}\overrightarrow{\mathrm{O}M}}{\mathrm{d}s}\frac{\mathrm{d}t}{\mathrm{d}s}\Rightarrow\vec{T}=\begin{pmatrix}\dfrac{1}{\sqrt{1+4t^2}}\\ \dfrac{1}{\sqrt{1+4t^2}}2t\end{pmatrix}\tag{8.6.81}$$

By the way you will notice that we have well:

$$\|\vec{T}\|=1\tag{8.6.82}$$

Thus, the curvature (inverse of the radius of curvature) is given by:

$$\begin{aligned}\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}&=\frac{\mathrm{d}\overrightarrow{\mathrm{O}M}}{\mathrm{d}t}\frac{\mathrm{d}t}{\mathrm{d}s}=\begin{pmatrix}\left(-4\dfrac{t}{(1+4t^2)^{3/2}}\right)\dfrac{1}{\sqrt{1+4t^2}}\\ \left(\dfrac{2}{\sqrt{1+4t^2}}-8\dfrac{t^2}{(1+4t^2)^{3/2}}\right)\dfrac{1}{\sqrt{1+4t^2}}\end{pmatrix}\\ &=\begin{pmatrix}\dfrac{-4t}{(1+4t^2)^2}\\ \dfrac{2}{1+4t^2}-\dfrac{8t^2}{(1+4t^2)^2}\end{pmatrix}\frac{1}{R(t)}\Rightarrow\left\|\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}\right\|=\sqrt{\frac{4}{(1+4t^2)^3}}=\frac{2}{(1+4t^2)^{3/2}}\end{aligned}\tag{8.6.83}$$

And therefore:

$$R(t)=\frac{(1+4t^2)^{3/2}}{2}\tag{8.6.84}$$

At $t=0$ the parabola has therefore a curvature $R(0)=0.5$. We have the vectors at $t=0$:

$$\vec{T}=\begin{pmatrix}1\\0\end{pmatrix}\qquad\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}=\begin{pmatrix}0\\2\end{pmatrix}\qquad\vec{N}=R\frac{\mathrm{d}\vec{T}}{\mathrm{d}s}=\begin{pmatrix}0\\1\end{pmatrix}\tag{8.6.85}$$

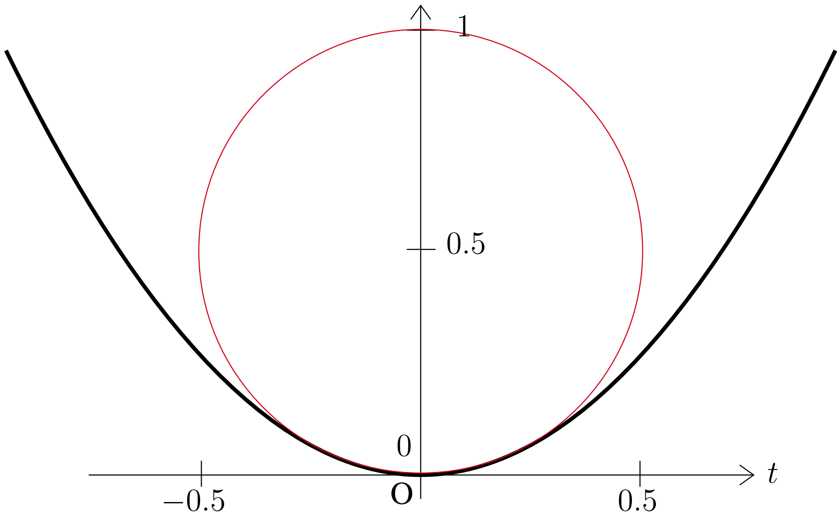

Figure 8.209: Osculating circle to parabola at point $t=0$

E2. Let us seek the radius and the center of curvature for any M of our helix defined above as practical example. Recall that its parametric function is given by:

$$\overrightarrow{\text{O}M}=\begin{pmatrix}x\\y\\z\end{pmatrix}=\begin{pmatrix}r\cos(t)\\r\sin(t)\\ht\end{pmatrix} \tag{8.6.86}$$

and that:

$$\dfrac{\mathrm{d}s}{\mathrm{d}t}=\sqrt{r^2+h^2} \tag{8.6.87}$$

Therefore we have:

$$\vec{T}=\dfrac{\mathrm{d}\overrightarrow{\text{O}M}}{\mathrm{d}s}=\dfrac{\mathrm{d}\overrightarrow{\text{O}M}}{\mathrm{d}t}\dfrac{\mathrm{d}t}{\mathrm{d}s}\Rightarrow\vec{T}=\begin{pmatrix}-\dfrac{r}{\sqrt{r^2+h^2}}\sin(t)\\\dfrac{r}{\sqrt{r^2+h^2}}\cos(t)\\\dfrac{h}{\sqrt{r^2+h^2}}\end{pmatrix} \tag{8.6.88}$$

On the way, the reader will have probably noticed that we have:

$$\|\vec{T}\|=1 \tag{8.6.89}$$

Thus, the curvature (the inverse of the radius of curvature) is given by:

$$\dfrac{\mathrm{d}\vec{T}}{\mathrm{d}t}=\dfrac{\mathrm{d}\vec{T}}{\mathrm{d}t}\dfrac{\mathrm{d}t}{\mathrm{d}s}=\begin{pmatrix}-\dfrac{r}{r^2+h^2}\cos(t)\\-\dfrac{r}{r^2+h^2}\sin(t)\\0\end{pmatrix}=\left\|\dfrac{\mathrm{d}\vec{T}}{\mathrm{d}s}\right\|=\dfrac{r}{r^2+h^2} \tag{8.6.90}$$

Therefore the radius of curvature is equal to:

$$R=\dfrac{r^2+h^2}{r} \tag{8.6.91}$$

This is consistent with intuition because when the step h of the helix is equal to zero, the radius or curvature is equal to r (the radius of the corresponding circle) and when h tends to infinity the radius of curvature tends to infinity and the curvature tends to zero. This example is a famous case in engineering applied to the exhaust chimney of smoke evacuation which are surrounded by a spiral of Archimedes and whose objective is to raise the air flows upward (the difficulty being to identify the radius R of the metal plate to cut that will follow the desired curvature at best... at least locally by knowing the radius of the chimney and the height h of the step of the helix):

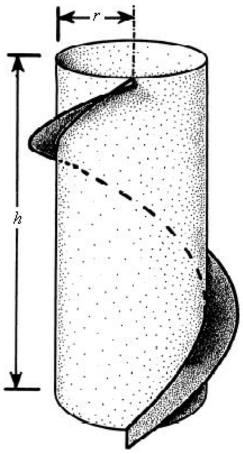

Figure 8.210: **Basic principle of an industrial chimney with a spiral (source: Frank Morgan, Riemmanian Geometry)**

Or the real corresponding version:

Figure 8.211: **Industrial evacuation chimney with spiral**

But in this engineering case, the height h should be obtained by a complete rotation. Therefore the radius of curvature will be written:

$$R = \frac{r^2 + \left(\dfrac{h}{2\pi}\right)^2}{r} \tag{8.6.92}$$

Anyway, to get back to our example and finish it, it comes with the first Frenet formula the following normal vector:

$$\vec{N} = \begin{pmatrix} -\cos(t) \\ -\sin(t) \\ 0 \end{pmatrix} \tag{8.6.93}$$

and for which the point (extremity of the vector) are indistinctness of the z-axis (merged with it) of our helix regardless the height h! The coordinate of the component z of this vector is zero since the normal is taken with respect to a point M of the curve already at a given implicit height h.

By the third Frenet formula with the binormal vector:

$$\begin{aligned}\vec{B}=\vec{T}\times\vec{N}&=\begin{pmatrix}-\dfrac{r}{\sqrt{r^2+h^2}}\sin(t)\\ \dfrac{r}{\sqrt{r^2+h^2}}\cos(t)\\ \dfrac{h}{\sqrt{r^2+h^2}}\sin(t)\end{pmatrix}\times\begin{pmatrix}-\cos(t)\\-\sin(t)\\0\end{pmatrix}\\ &=\frac{1}{\sqrt{r^2+h^2}}\begin{pmatrix}r\cos(t)\cdot 0-h(-\sin(t))\\ h(-\cos(t))-(-r\sin(t))\cdot 0\\ (-r\sin(t))(-\sin(t))-r\cos(t)(-\cos(t))\end{pmatrix}\end{aligned} \tag{8.6.94}$$

and the torsion radius is given by the relation:

$$\frac{\mathrm{d}\vec{B}}{\mathrm{d}s}=\frac{\vec{N}}{R'} \tag{8.6.95}$$

we therefore have:

$$\vec{N}=R'\frac{\mathrm{d}\vec{B}}{\mathrm{d}s}=R'\frac{\mathrm{d}\vec{B}}{\mathrm{d}t}\frac{\mathrm{d}t}{\mathrm{d}s} \tag{8.6.96}$$

And as we got the three following relations:

$$\vec{N}=\begin{pmatrix}-\cos(t)\\-\sin(t)\\0\end{pmatrix}\qquad\frac{\mathrm{d}\vec{B}}{\mathrm{d}t}=\begin{pmatrix}\dfrac{h}{\sqrt{r^2+h^2}}\cos(t)\\ \dfrac{h}{\sqrt{r^2+h^2}}\sin(t)\\0\end{pmatrix}\qquad\frac{\mathrm{d}t}{\mathrm{d}s}=\frac{1}{\sqrt{r^2+h^2}} \tag{8.6.97}$$

We deduce the torsion radius:

$$R'=-\frac{r^2+h^2}{h} \tag{8.6.98}$$

Let us now determine the important case of the explicit expression of the radius of curvature in Cartesian coordinates (result used in the section of Civil Engineering and useful in many other areas of physics!). Consider for this purpose the following figure:

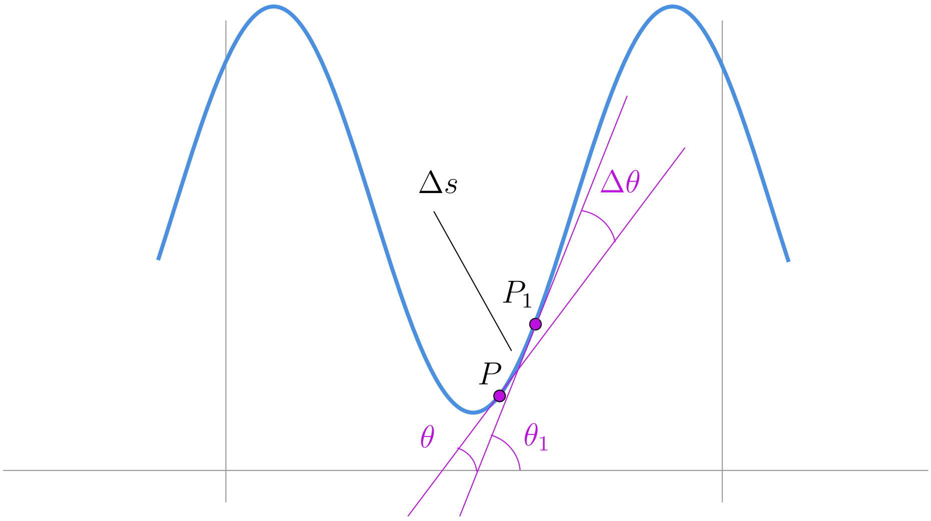

Figure 8.212: **Illustrated approach of the "1D" curvature expression**

So we have the radius of curvature which is intuitively given by the following relation if we do not make use of vector analysis:

$$C=\lim_{\Delta\to\theta}\frac{\Delta\theta}{\Delta s}=\frac{\mathrm{d}\theta}{\mathrm{d}\theta} \tag{8.6.99}$$

We also have:

$$\frac{\mathrm{d}\theta}{\mathrm{d}s}=\frac{\mathrm{d}\theta}{\mathrm{d}x}\frac{\mathrm{d}x}{\mathrm{d}s} \tag{8.6.100}$$

and as:

$$\tan(\theta)=\frac{\mathrm{d}y}{\mathrm{d}x} \tag{8.6.101}$$

therefore we have:

$$\theta=\arctan\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right) \tag{8.6.102}$$

and therefore:

$$\frac{\mathrm{d}\theta}{\mathrm{d}x}=\frac{\mathrm{d}}{\mathrm{d}x}\left(\arctan\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)\right) \tag{8.6.103}$$

We have proved in the section of Differential and Integral Calculus the following derivative (see page 1475):

$$\frac{\mathrm{d}}{\mathrm{d}x}\arctan(x)=\frac{1}{1+x^2} \tag{8.6.104}$$

We then have immediately by the composed derivatives:

$$\frac{\mathrm{d}\theta}{\mathrm{d}x}=\frac{\mathrm{d}}{\mathrm{d}x}\left(\arctan\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)\right)=\frac{1}{1+\left(\dfrac{\mathrm{d}y}{\mathrm{d}x}\right)^2}\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)=\frac{\dfrac{\mathrm{d}^2y}{\mathrm{d}x^2}}{1+\left(\dfrac{\mathrm{d}y}{\mathrm{d}x}\right)^2} \tag{8.6.105}$$

Having done this we also need $\mathrm{d}x/\mathrm{d}s$. But, we have already proved with different approaches in the section of Analytical Mechanics and Geometric Shapes (among others) by simply using Pythagoras theorem that:

$$\frac{\mathrm{d}x}{\mathrm{d}s}=\frac{1}{\dfrac{\mathrm{d}s}{\mathrm{d}x}}=\frac{1}{\sqrt{1+\left(\dfrac{\mathrm{d}y}{\mathrm{d}x}\right)^2}} \tag{8.6.106}$$

By grouping all we finally have:

$$C=\frac{\mathrm{d}\theta}{\mathrm{d}s}=\frac{\mathrm{d}\theta}{\mathrm{d}x}\frac{\mathrm{d}x}{\mathrm{d}s}=\frac{\dfrac{\mathrm{d}^2y}{\mathrm{d}x^2}}{1+\left(\dfrac{\mathrm{d}y}{\mathrm{d}x}\right)^2}\frac{1}{\sqrt{1+\left(\dfrac{\mathrm{d}y}{\mathrm{d}x}\right)^2}}=\frac{\dfrac{\mathrm{d}^2y}{\mathrm{d}x^2}}{\left(1+\left(\dfrac{\mathrm{d}y}{\mathrm{d}x}\right)^2\right)^{3/2}}=\frac{y''}{(1+y'^2)^{3/2}} \tag{8.6.107}$$

So it comes that the radius of the local osculating circle of a Cartesian function in the plane (by taking the absolute value of the second derivative to avoid having a negative radius...) is given by:

$$\boxed{R=\frac{1}{C}=\frac{\left(1+\left(\dfrac{\mathrm{d}y}{\mathrm{d}x}\right)^2\right)^{3/2}}{\left|\dfrac{\mathrm{d}^2y}{\mathrm{d}x^2}\right|}=\frac{(1+y'^2)^{3/2}}{|y''|}} \tag{8.6.108}$$

The last relation is often denoted in other textbooks as:

$$\kappa=\frac{|y''|}{(1+y'^2)^{3/2}} \tag{8.6.109}$$

Let us now derive another famous expression for the curvature based on the method and notation given in [323].

We start again from:

$$\begin{aligned}\kappa:=\frac{\mathrm{d}\phi}{\mathrm{d}s}=\frac{\dfrac{\mathrm{d}\phi}{\mathrm{d}t}}{\dfrac{\mathrm{d}s}{\mathrm{d}t}}&=\frac{\dfrac{\mathrm{d}\phi}{\mathrm{d}t}}{\sqrt{\left(\dfrac{\mathrm{d}x}{\mathrm{d}t}\right)^2+\left(\dfrac{\mathrm{d}y}{\mathrm{d}t}\right)^2}}\\&=\frac{\dfrac{\mathrm{d}\phi}{\mathrm{d}t}}{\sqrt{x'^2+y'^2}}\end{aligned} \tag{8.6.110}$$

where ϕ is the tangential angle and s is the arc length. The $\mathrm{d}\phi/\mathrm{d}t$ derivative in the above equation can be found using the identity:

$$\tan(\phi)=\frac{\mathrm{d}y}{\mathrm{d}x}=\frac{\mathrm{d}y/\mathrm{d}t}{\mathrm{d}x/\mathrm{d}t}=\frac{y'}{x'} \tag{8.6.111}$$

So:

$$\frac{\mathrm{d}}{\mathrm{d}t}\tan(\phi)=\sec^2(\phi)\frac{\mathrm{d}\phi}{\mathrm{d}t}=\frac{x'y''-y'x''}{x'^2} \tag{8.6.112}$$

Therefore:

$$\begin{aligned}\frac{\mathrm{d}\phi}{\mathrm{d}t}&=\frac{1}{\sec^2(\phi)}\frac{\mathrm{d}}{\mathrm{d}t}(\tan\phi)=\frac{1}{1+\tan^2(\phi)}\frac{x'y''-y'x''}{x'^2}\\&=\frac{1}{1+\frac{y'^2}{x'^2}}\frac{x'y''-y'x''}{x'^2}=\frac{x'y''-y'x''}{x'^2+y'^2}\end{aligned} \tag{8.6.113}$$

Hence:

$$\boxed{\kappa=\frac{x'y''-y'x''}{(x'^2+y'^2)^{3/2}}} \tag{8.6.114}$$

Let us derive now a third quite famous expression for the curvature based on the method and notation given in [2].

We start again from:

$$\hat{\vec{T}}:=\frac{\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}}{\left\|\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}\right\|}=\frac{\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}}{\frac{\mathrm{d}s}{\mathrm{d}t}} \tag{8.6.115}$$

Therefore:

$$\begin{aligned}\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}&=\frac{\mathrm{d}s}{\mathrm{d}t}\hat{\vec{T}}\\\frac{\mathrm{d}^2\vec{r}}{\mathrm{d}t^2}&=\frac{\mathrm{d}^2s}{\mathrm{d}t^2}\hat{\vec{T}}+\frac{\mathrm{d}s}{\mathrm{d}t}\frac{\mathrm{d}\hat{\vec{T}}}{\mathrm{d}t}\\&=\frac{\mathrm{d}^2s}{\mathrm{d}t^2}\hat{\vec{T}}+\kappa\hat{\vec{N}}\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^2\end{aligned} \tag{8.6.116}$$

where $\hat{\vec{N}}$ is the normal vector. But:

$$\begin{aligned}\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}\times\frac{\mathrm{d}^2\vec{r}}{\mathrm{d}t^2}&=\frac{\mathrm{d}s}{\mathrm{d}t}\frac{\mathrm{d}^2s}{\mathrm{d}t^2}(\hat{\vec{T}}\times\hat{\vec{T}})+\kappa\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^3(\hat{\vec{T}}\times\hat{\vec{N}})=\frac{\mathrm{d}s}{\mathrm{d}t}\frac{\mathrm{d}^2s}{\mathrm{d}t^2}\vec{0}+\kappa\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^3(\hat{\vec{T}}\times\hat{\vec{N}})\\&=\kappa\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^3(\hat{\vec{T}}\times\hat{\vec{N}})\end{aligned} \tag{8.6.117}$$

so taking norms of both sides gives:

$$\left\|\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}\times\frac{\mathrm{d}^2\vec{r}}{\mathrm{d}t^2}\right\|=\kappa\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^3=\kappa\left\|\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}\right\|^3 \tag{8.6.118}$$

Solving for κ then gives:

$$\kappa=\left\|\frac{\mathrm{d}\hat{\vec{T}}}{\mathrm{d}s}\right\|=\frac{\left\|\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}\times\frac{\mathrm{d}^2\vec{r}}{\mathrm{d}t^2}\right\|}{\left\|\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}\right\|^3}=\frac{\left\|\dot{\vec{r}}\times\ddot{\vec{r}}\right\|^3}{\left\|\dot{\vec{r}}\right\|^3} \tag{8.6.119}$$

Hence:

$$\boxed{\kappa = \frac{\left\| \dot{\vec{r}} \times \ddot{\vec{r}} \right\|^3}{\left\| \dot{\vec{r}} \right\|^3}} \tag{8.6.120}$$

8.6.4 Surface Patches

The study of surface patches is strongly related to the properties of parametric surfaces expression as seen at the end of the section of Analytical Geometry. We are therefore interested to calculate the tangent plane and the curvature of a surface on a given point. It is therefore an extension of the previous subjects. For example, the study of isolines of a surface that we have seen earlier can also be considered as belonging the field of Surface Patches study.

Now let us consider to begin $D \subset \mathbb{R}^2$:

$$g\begin{pmatrix} D \to \mathbb{R}^3 \\ (u,v) \to g(u,v) = M \end{pmatrix} \tag{8.6.121}$$

with:

$$\overrightarrow{\text{O}M} = \begin{pmatrix} x(u,v) \\ y(u,v) \\ z(u,v) \end{pmatrix} \tag{8.6.122}$$

such that $h(I) \subset D$.

We can define $g \circ h$:

$$g \circ h\begin{pmatrix} I \to \mathbb{R}^3 \\ t \to (g \circ h)(t) = g(u(t), v(t)) \end{pmatrix} \tag{8.6.123}$$

If we assume h continuous, it is clear that $g \circ h$ is a parametric arc. Let us denote by Γ its support, we have $\Sigma \subset \Sigma$ and we say that Σ a "plotted curve" or "inscribed curve" on Σ defined by the "Gauss Coordinates" u and v (already seen in the section of Non-Euclidean Geometry).

Remark

We always assume now that $D = I \times J$.

Given $M_0 \in \Sigma$, $M_0 = g(u_0, v_0)$. Let us look at the two curves drawn on Σ defined by the following parametrized arcs:

$$(g_{v_0}, I) \text{ with } g_{v_0}\begin{pmatrix} I \to \mathbb{R}^3 \\ u \to g_{v_0} = g(u, v_0) \end{pmatrix} \tag{8.6.124}$$

$$(g_{u_0}, J) \text{ with } g_{u_0}\begin{pmatrix} J \to \mathbb{R}^3 \\ v \to g_{u_0} = g(u_0, v) \end{pmatrix} \tag{8.6.125}$$

g_{u_0} and g_{v_0} are the two functions named "partial functions" of g on (u_0, v_0).

The support of (g_{u_0}, J) and (g_{v_0}, I) are named "coordinate-curves" of Σ on M_0 relatively to the parametrization (g, D). We denote them respectively Γ_{u_0} and Γ_{v_0} (see figure below). We also name Γ_{u_0} "first coordinate-curve" and Γ_{v_0} "second coordinate-curve".

It is of course quite obvious that (see section Differential and Integral Calculus page 1465) that:

$$\frac{\mathrm{d}g_{u_0}}{\mathrm{d}v} = \frac{\partial g}{\partial v} = \frac{\partial \overrightarrow{\text{O}M}}{\partial v} \tag{8.6.126}$$

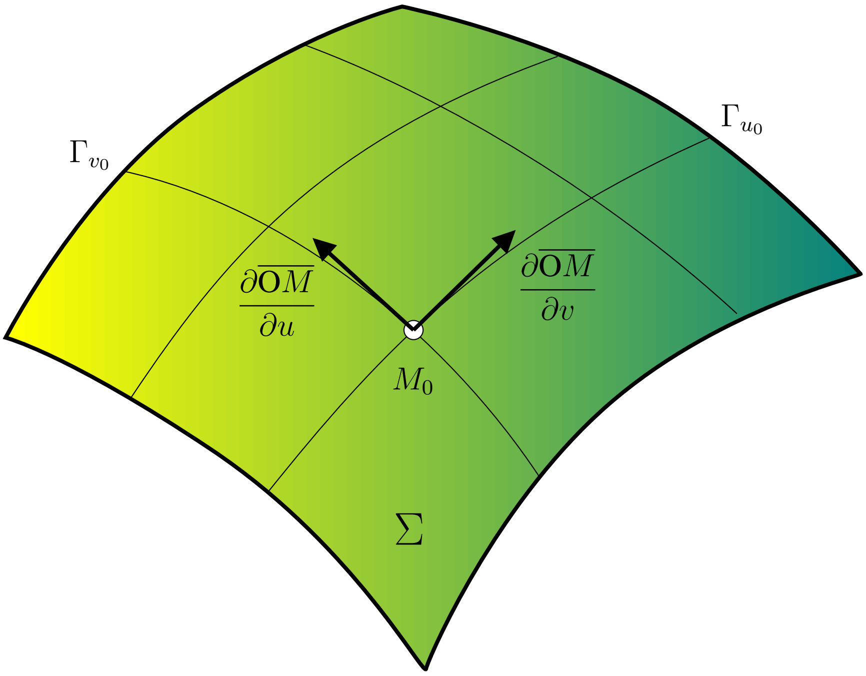
is tangent to Γ_{u_0} on M_0 and that $\partial\overrightarrow{\text{O}M}/\partial u$ is tangent to Γ_{v_0} on M_0.

As we have already prove it in the section of Tensor Calculus, this expression is independent of the surface patch as the infinitesimal element length $\mathrm{d}s$ is independent of the parametrization of Σ. This quadratic form is therefore an invariant that represents the metric of Σ. It is also denoted as follows by tradition:

$$\boxed{\mathrm{d}s^2 = g_{uu}\mathrm{d}u^2 + 2g_{uv}\mathrm{d}u\mathrm{d}v + g_{vv}\mathrm{d}2} \tag{8.6.127}$$

or even in more condensed form using tensor notation:

$$\mathrm{d}s^2 = g_{\mu\nu}\mathrm{d}x^\mu\mathrm{d}x^\nu \tag{8.6.128}$$



Γ_{v_0}
Γ_{u_0}

Σ

Figure 8.213: Representation of a surface patch

8.6.4.1 Metric of a Surface Patch

Given again:

$$g\begin{pmatrix} D \rightarrow \mathbb{R}^3 \\ (u,v) \rightarrow g(u,v) = M \end{pmatrix} \tag{8.6.129}$$

with:

$$\overrightarrow{\text{O}M} = \begin{pmatrix} x(u,v) \\ y(u,v) \\ z(u,v) \end{pmatrix} \tag{8.6.130}$$

Let us write $\mathrm{d}g = (\mathrm{d}x, \mathrm{d}y, \mathrm{d}z)$ or in other words:

$$\mathrm{d}\overrightarrow{\text{O}M} = \begin{pmatrix} \mathrm{d}x \\ \mathrm{d}y \\ \mathrm{d}z \end{pmatrix} \tag{8.6.131}$$

We also have (see section Differential and Integral Calculus page 1466):

$$\begin{aligned}\mathrm{d}x&=\frac{\partial x}{\partial u}\mathrm{d}u+\frac{\partial x}{\partial v}\mathrm{d}v\\ \mathrm{d}y&=\frac{\partial y}{\partial u}\mathrm{d}u+\frac{\partial y}{\partial v}\mathrm{d}v\\ \mathrm{d}z&=\frac{\partial z}{\partial u}\mathrm{d}u+\frac{\partial z}{\partial v}\mathrm{d}v\end{aligned} \tag{8.6.132}$$

and we have proved at the beginning of this section that the curvilinear abscissa in a Cartesian space (in Riemann coordinates Riemann) was given by:

$$\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2 \tag{8.6.133}$$

We therefore have after substitution in Gaussian coordinates and grouping terms of the same type:

$$\begin{aligned}\mathrm{d}s^2=&\left[\left(\frac{\partial x}{\partial u}\right)^2+\left(\frac{\partial y}{\partial u}\right)^2+\left(\frac{\partial z}{\partial u}\right)^2\right]^2\mathrm{d}u^2+2\left[\frac{\partial x}{\partial u}\frac{\partial x}{\partial v}+\frac{\partial y}{\partial u}\frac{\partial y}{\partial v}+\frac{\partial z}{\partial u}\frac{\partial z}{\partial v}\right]\mathrm{d}u\mathrm{d}v\\ &+\left[\left(\frac{\partial x}{\partial v}\right)^2+\left(\frac{\partial y}{\partial v}\right)^2+\left(\frac{\partial z}{\partial v}\right)^2\right]^2\mathrm{d}v^2\end{aligned} \tag{8.6.134}$$

Which is equivalent to write (take caution not to read there the square of a vector but it is the dot product of the vector with itself!):

$$\mathrm{d}s^2=\left(\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\right)^2\mathrm{d}u^2+2\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}\mathrm{d}u\mathrm{d}v+\left(\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}\right)^2\mathrm{d}v^2 \tag{8.6.135}$$

In a more traditional way with the notation:

$$E=\left(\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\right)^2\qquad F=\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}\qquad G=\left(\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}\right)^2 \tag{8.6.136}$$

we get a relation named the "first fundamental quadratic form" (we will note prove in this textbook the second one):

$$\mathrm{d}s^2=E\mathrm{d}u^2+2F\mathrm{d}u\mathrm{d}v+G\mathrm{d}v^2 \tag{8.6.137}$$

also named "first Gauss differential form". It is interesting to write this last relation in the form:

$$\mathrm{d}s^2=\frac{1}{E}(E\mathrm{d}u+F\mathrm{d}v)^2+\frac{EG-F^2}{E}\mathrm{d}v \tag{8.6.138}$$

and we see for $\mathrm{d}s^2$ to be positive, E and also $EG-F^2$ must be positive!

The first fundamental form may be also represented as a symmetric matrix:

$$\mathrm{d}s^2=\vec{u}^T\begin{bmatrix}E & G\\ F & G\end{bmatrix}\vec{v} \tag{8.6.139}$$

The first fundamental form is often written in the modern notation of the metric tensor. The coefficients may then be written as g_{ij}:

$$g_{ij}=\begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix}=\begin{bmatrix} E & F \\ F & G \end{bmatrix} \tag{8.6.140}$$

and we will prove in the section of Tensor Calculus during our study of Gram's determinant (see page 2054) that this relation can be used to calculate the surface of any (regular) surface patch!!

8.6.4.1.1 Regularity of a Surface

Definition (#8.6.363): A point M belonging to the surface Σ is said (this is quite relatively logical...) a "regular point" if and only if:

$$\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\times\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}\neq\vec{0} \tag{8.6.141}$$

A surface patch is logically named "smooth surface" if and only if all its points are regular (if the cross product is zero then there is somewhere a "fold" at $\pi/2$... and this is quite annoying for continuity purposes).

Let us notice that:

$$\begin{aligned}
&\left\|\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\times\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}\right\|^2=\left\|\begin{pmatrix}\dfrac{\partial x(u,v)}{\partial u}\\ \dfrac{\partial y(u,v)}{\partial u}\\ \dfrac{\partial u(u,v)}{\partial u}\end{pmatrix}\times\begin{pmatrix}\dfrac{\partial x(u,v)}{\partial v}\\ \dfrac{\partial y(u,v)}{\partial v}\\ \dfrac{\partial u(u,v)}{\partial v}\end{pmatrix}\right\|^2=\left\|\begin{pmatrix}\partial_u y\partial_v z-\partial_u z\partial_v y\\ \partial_u z\partial_v x-\partial_u x\partial_v z\\ \partial_u x\partial_v y-\partial_u y\partial_v x\end{pmatrix}\right\|^2\\
&=\left\|\sqrt{(\partial_u y\partial_v z-\partial_u z\partial_v y)^2+(\partial_u z\partial_v x-\partial_u x\partial_v z)^2+(\partial_u x\partial_v y-\partial_u y\partial_v x)^2}\right\|\\
&=(\partial_u y\partial_v z-\partial_u z\partial_v y)^2+(\partial_u z\partial_v x-\partial_u x\partial_v z)^2+(\partial_u x\partial_v y-\partial_u y\partial_v x)^2\\
&=(\partial_u y\partial_v z)^2-2\partial_u y\partial_v z\partial_u z\partial_v y+(\partial_u z\partial_v y)^2\\
&+(\partial_u z\partial_v x)^2-2\partial_u z\partial_v x\partial_u x\partial_v z+(\partial_u x\partial_v z)^2\\
&+(\partial_u x\partial_v y)^2-2\partial_u x\partial_v y\partial_u y\partial_v x+(\partial_u y\partial_v x)^2\\
&=\ldots\text{boring to do algebra}\ldots=EG-F^2
\end{aligned} \tag{8.6.142}$$

The angle α between the two coordinate-curves Γ_{u_0} and Γ_{v_0} to Σ on M_0 is given by the product definition of the dot product:

$$\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\circ\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}=\left\|\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\right\|\left\|\frac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}\right\|\cos(\alpha)=F=0 \tag{8.6.143}$$

Hence the expression:

$$\cos(\alpha)=\frac{\dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\circ\dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}}{\left\|\dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\right\|\left\|\dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}\right\|}=\frac{\dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\circ\dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}}{\sqrt{\left(\dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}\right)^2\left(\dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial v}\right)^2}}=\frac{F}{\sqrt{EG}} \tag{8.6.144}$$

Therefore a necessary and sufficient condition for the coordinates-curves Γ_{u_0} and Γ_{v_0} to be perpendicular to Σ on M_0 is that F is equal to zero. In this particular case, we say that the curvilinear coordinates u, v on the surface are orthogonal coordinates!!!

✍**Examples:**

E1. Let us consider the parametrization of the cartesian plane. Then we have:

$$\overrightarrow{\text{O}M}=\begin{pmatrix}x\\y\\0\end{pmatrix}\Rightarrow\begin{cases}\dfrac{\partial\overrightarrow{\text{O}M}}{\partial x}=\begin{pmatrix}1\\0\\0\end{pmatrix}\\[2ex]\dfrac{\partial\overrightarrow{\text{O}M}}{\partial y}=\begin{pmatrix}0\\1\\0\end{pmatrix}\end{cases}\tag{8.6.145}$$

hence:

$$E=G=1,F=0\tag{8.6.146}$$

Therefore:

$$\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2\tag{8.6.147}$$

We fall back on the same differential curvilinear abscissa than that seen in the section of Tensor Calculus and General Relativity with the diagonal metric of the flat space.

We also have:

$$EG-F^2=1\neq 0\tag{8.6.148}$$

Then the surface is indeed regular.

We also have:

$$\cos(\alpha)=\frac{F}{\sqrt{EG}}=\frac{0}{\sqrt{1}}=0\Rightarrow\alpha=\pm\frac{\pi}{2}\tag{8.6.149}$$

So the both coordinate-curves are perpendicular!

E2. Let us consider the parametrization of the cylinder surface. We then have (see section Vector Calculus page 1861):

$$\overrightarrow{\text{O}M}=\begin{pmatrix}r\cos(\phi)\\r\sin(\phi)\\z\end{pmatrix}\Rightarrow\begin{cases}\dfrac{\partial\overrightarrow{\text{O}M}}{\partial r}=\begin{pmatrix}\cos(\phi)\\\sin(\phi)\\0\end{pmatrix}\\[2ex]\dfrac{\partial\overrightarrow{\text{O}M}}{\partial \phi}=\begin{pmatrix}-r\sin(\phi)\\r\cos(\phi)\\0\end{pmatrix}\end{cases}\tag{8.6.150}$$

hence:

$$E=1,G=r^2,F=0\tag{8.6.151}$$

Therefore:

$$\mathrm{d}s^2=\mathrm{d}r^2+r^2\mathrm{d}\phi^2\tag{8.6.152}$$

We fall back on the same differential curvilinear abscissa than that seen in the section of Tensor Calculus and General Relativity with the diagonal metric in polar coordinates.

We also have:

$$EG-F^2=r^2\neq 0 \tag{8.6.153}$$

Therefore the surface is regular as long as r is not zero. We also have:

$$\cos(\alpha)=\frac{F}{\sqrt{EG}}=\frac{0}{\sqrt{r^2}}\Rightarrow\alpha=\pm\frac{\pi}{2} \tag{8.6.154}$$

So the both coordinates-curves are perpendicular on the cylinder.

E3. Let us consider the parametrization of the sphere of origin O and radius r . Then we have (see section Vector Calculus page 1849):

$$\overrightarrow{\text{O}M}=\begin{pmatrix}r\sin(\theta)\cos(\phi)\\ r\sin(\theta)\sin(\phi)\\ r\cos(\theta)\end{pmatrix}\Rightarrow\begin{cases}\dfrac{\partial\overrightarrow{\text{O}M}}{\partial\theta}=\begin{pmatrix}r\cos(\theta)\cos(\phi)\\ r\cos(\theta)\sin(\phi)\\ -r\sin(\theta)\end{pmatrix}\\ \dfrac{\partial\overrightarrow{\text{O}M}}{\partial\phi}=\begin{pmatrix}-r\sin(\theta)\sin(\phi)\\ r\sin(\theta)\cos(\phi)\\ 0\end{pmatrix}\end{cases} \tag{8.6.155}$$

hence:

$$E=r^2,G=r^2\sin^2(\theta),F=0 \tag{8.6.156}$$

Therefore:

$$\mathrm{d}s^2=r^2\mathrm{d}\theta^2+r^2\sin^2(\theta)\mathrm{d}\phi^2 \tag{8.6.157}$$

We fall back on the same differential curvilinear abscissa than that seen in the section of Tensor Calculus and General Relativity with the diagonal metric in spherical coordinates.

We also have:

$$EG-F^2=r^4\sin^2(\theta)\neq 0 \tag{8.6.158}$$

Therefore the surface is regular as long as r and θ are not zero. We also have:

$$\cos(\alpha)=\frac{F}{\sqrt{EG}}=\frac{0}{\sqrt{r^4\sin^2(\theta)}}\Rightarrow\alpha=\pm\frac{\pi}{2} \tag{8.6.159}$$

So the both coordinates-curves are perpendicular on the sphere.

E4. Let us consider the parametrization of the hyperboloid. Then we have (see section Analytical Geometry page 2841):

$$\overrightarrow{\mathrm{O}M}=\begin{pmatrix}a\sqrt{1+t^2}\cos(u)\\ a\sqrt{1+t^2}\sin(u)\\ bu\end{pmatrix}\Rightarrow\begin{cases}\dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial t}=\begin{pmatrix}a\dfrac{a\cos(u)t}{\sqrt{1+t^2}}\\ a\dfrac{a\sin(u)t}{\sqrt{1+t^2}}\\ 0\end{pmatrix}\\ \dfrac{\partial\overrightarrow{\mathrm{O}M}}{\partial u}=\begin{pmatrix}-a\sqrt{1+t^2}\sin(u)\\ a\sqrt{1+t^2}\cos(u)\\ b\end{pmatrix}\end{cases}\tag{8.6.160}$$

hence:

$$E=a^2\frac{t^2}{1+t^2},G=a^2(1+t^2)+b^2,F=0\tag{8.6.161}$$

Therefore:

$$\mathrm{d}s^2=a^2\frac{t^2}{1+t^2}\mathrm{d}t^2+(a^2(1+t^2)+b^2)\mathrm{d}u^2\tag{8.6.162}$$

Let us take b as being equal to zero. Then we have:

$$EG-F^2=a^4t^2\tag{8.6.163}$$

Therefore the surface is regular as long as a not equal to zero. We also have:

$$\cos(\alpha)=\frac{F}{\sqrt{EG}}=\frac{0}{\sqrt{a^4t^2}}\Rightarrow\alpha=\pm\frac{\pi}{2}\tag{8.6.164}$$

So the both coordinates-curves are perpendicular on the hyperboloid.

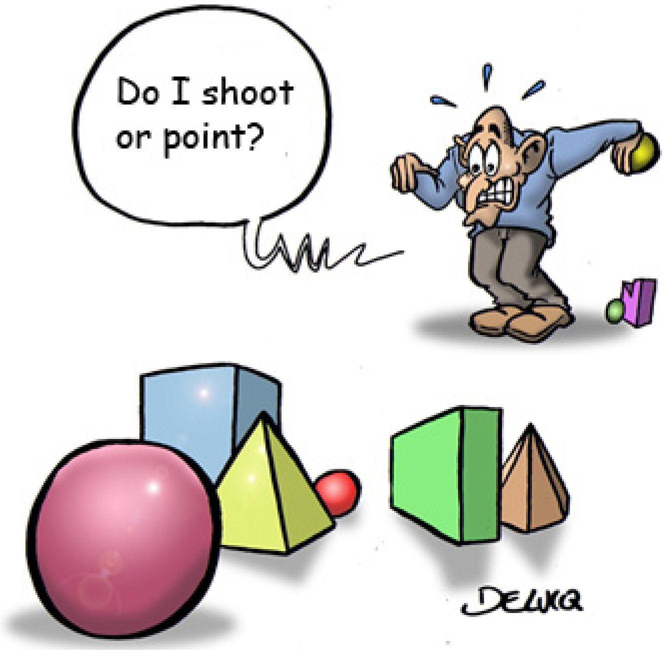
8.7. Geometric Shapes

We have already defined at the beginning of the section on Euclidean Geometry the concepts of topological dimensions, what were a zero-dimensional point and a unit dimensional curve. We will not come back on these concepts we will focus here mostly on shapes of higher dimensions that we will use a lot in the chapters related to theoretical Physics.

The purpose of section is to categorize with proofs some remarkable mathematical properties of well-known geometric shapes and bodies (area, volume, center of mass, moment of inertia). Indeed, there are many mathematical books listing those properties without proofs but few or simply no books at all prove them all (at least we have never seen such a book at this day...). The list below is at this date far away to exhaustive (since there are an infinite number of geometric shapes), but it will be completed in time.



Do I shoot or point?
DELUKA

The few shapes that we wanted to present in this section allow easily to find the remarkable properties of a large number of shapes not listed in this section by assembly or decomposition.

Remarks

R1. The trigonometric relations and remarkable integrals that will be used for the study of the geometric shapes below are not proven in this section. They all have already been proved in the sections dealing specifically with Trigonometry (see page 2503) and Differential Calculus and Integral (see page 1450).

R2. We understand by "center of gravity", the "barycenter" as discussed in the chapter of Euclidean Geometry (see page 2635).

Here are some typical areas scales (the years are given relatively to the holocene calendar):

Magnitude $[\text{m}^2]$	**Description**
$2.6\cdot 10^{-70}$	Planck area $\frac{G\hbar}{c^3}$
$66.52\cdot 10^{-29}$	Thomson cross-section of the electron
$1\cdot 10^{-28}$	1 barn, roughly the cross-sectional area of a uranium nucleus
$7.17\cdot 10^{-9}$	A dot printed using 300 dots per inch resolution
$1\cdot 10^{-8}$	A red blood cell
$1.57\cdot 10^{-8}$	Cross-sectional area of a straight human hair
$2.4\cdot 10^{-8}$	Common LCD screen pixel sizes
$5.65\cdot 10^{-7}$	Cross-sectional area of a mechanical pencil lead
$1.5\cdot 10^{-7}$	Typical for one of the 20 standard amino acids
$1\cdot 10^{-6}$	Head of a pin
$6\cdot 10^{-6}$	E. coli bacterium
$4\cdot 10^{-5}$	Typical hole punched in a piece of paper by a hole punch
$2.9\cdot 10^{-4}$	One side of a U.S. penny
$5\cdot 10^{-4}$	Typical postage stamp
$1.1\cdot 10^{-3}$	Average human retina
$4.6\cdot 10^{-3}$	Face of a typical credit card
$6.237\cdot 10^{-2}$	International A4 paper (210×297 [mm])
0.125	International A3 paper (297×420 [mm])
0.25	International A2 paper (420×594 [mm])
0.5	International A1 paper (594×841 [mm])
1	International A0 paper (594×1189 [mm])
1-4	Top of an office desk
10-20	A typical parking space for tourists cars
100	One are
261	Size of a tennis court
845	Wing area of Airbus A380, the largest commercial airliner
978	Primary mirror of the Extremely Large Telescope, the largest optical telescope in the world (under construction)
$1,250$	Water in an Olympic-size swimming pool
$4,047$	1 acre
$7,140$	Typical football (soccer) field
$10,000$	1 hectare
$53,000$	Base of the Great Pyramid of Giza
$1.05\cdot 10^{8}$	Paris (inner city only)
$7.74\cdot 10^{12}$	Australia
$1.687\cdot 10^{14}$	Pacific Ocean
$5.1\cdot 10^{14}$	Earth
$6.1\cdot 10^{16}$	Jupiter
$6.1\cdot 10^{42}$	Approximate actual area of Milky Way's galactic disk
10^{54}	Approximate actual area the observable Universe

Table 8.6: **Some common areas scales**

8.7.1 Usual Surfaces (areas)

There are several definitions of the concept of surface (area) due to Euclid and another modern due to the topology (see sections of the corresponding names).

Definitions (#8.7.364):

D1. A "plane surface" is a closed area that can be identify almost approximatively by a height and a width.

D2. A "surface" is a topological variety of dimension 2.

Depending on the authors a surface or area is denoted by the symbols: $A, S, \mathcal{A}, \mathcal{S}, \Sigma$.

Remark

We will focus initially only on the properties (perimeter, area, center of gravity, etc.) of surfaces dived in Euclidean plane and space.

8.7.1.1 Polygons

Definition (#8.7.365): A "polygon" is a plane figure bounded by straight line segments (i.e.: with a closed polyline).

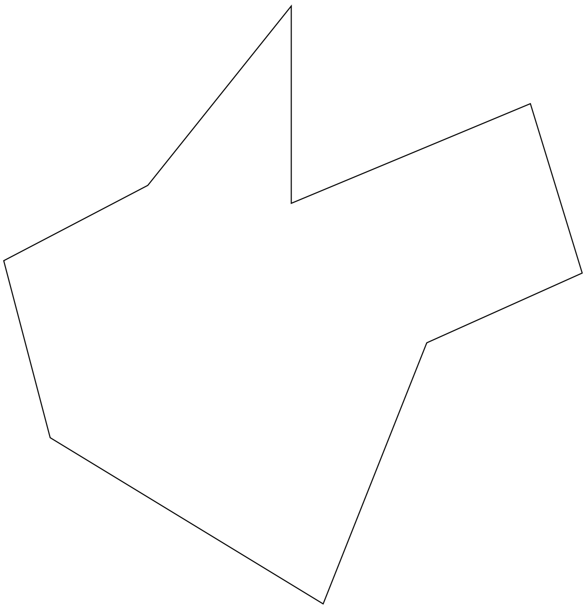


Figure 8.214: **Example of an arbitrary plane polygon**

Definition (#8.7.366): A "quadrilateral", "pentagon", "hexagon", "heptagon" are polygons with respectively four, five, six, seven... sides.

We distinguish three main families (but they are not the only ones!) of polygons:

1. Crossed polygons
2. Concave polygons (non-convex)
3. Convex polygons

We will find these two last families in different sections of this textbook (but for details see below).

Before going any further we would like to clarify to the reader that there is, at least as far as we know, only mathematical relations to calculate the surface for simple polygons. Although in practice we almost always meet non simple polygons and we considered as useless to dwell on the determination of a relation that would reduce the calculation of the surface of any polygon to that of simple polygons or to use Monte Carlo methods (see section of Numerical Methods page 6708).

Definition (#8.7.367): A polygon is named "crossed polygon" if at least two of its sides intersect, that is to say, if at least two of its sides cross each other.

This is the case of the polygone $ABCDE$ below:

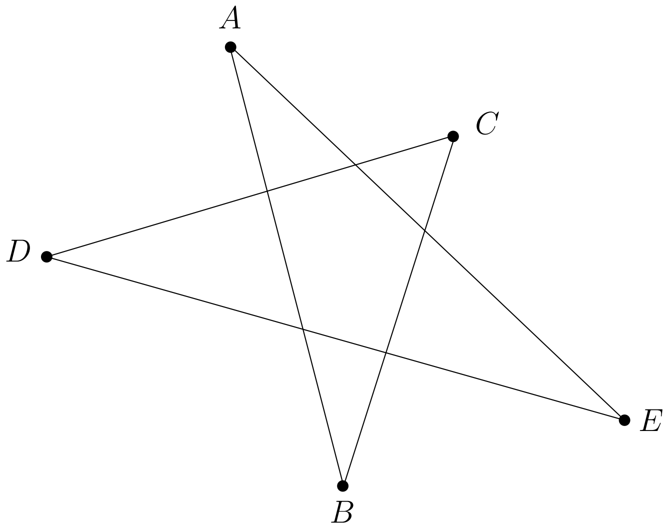

Figure 8.215: **Example of a crossed polygon**

Remark

The "envelope" of a polygon is the polygon obtained by following its outer contour. For example, the envelope of the previous polygon is a decagon whose vertices are the five summits of the pentagon and the five intersections of its sides.

Definition (#8.7.368): A polygon is named "concave polygon" if it is not crossed and if one or more of its diagonals are not entirely within the area bounded by the polygon.

This is the case of the pentagon $ABCDE$ below:

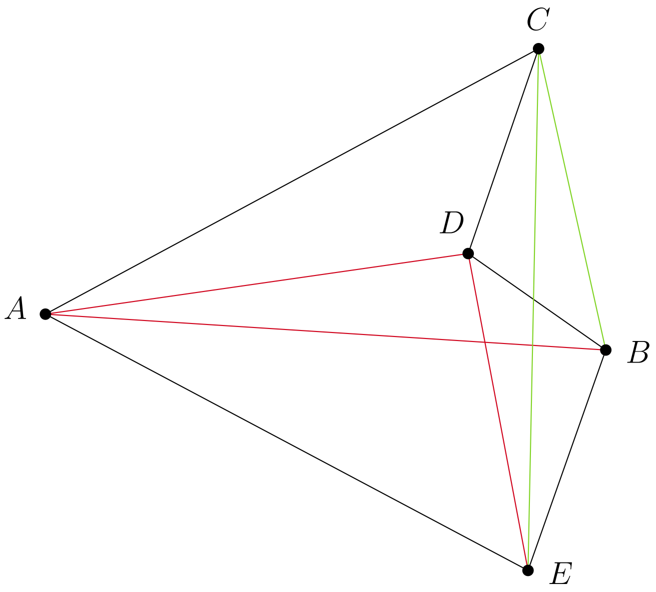

Figure 8.216: **Example of a concave polygon**

Definition (#8.7.369): A polygon is named "convex polygon" if it is not crossed and if all its diagonals are entirely within the area bounded by the polygon.

The hexagon $MNOPQR$ below is an example of convex polygon:

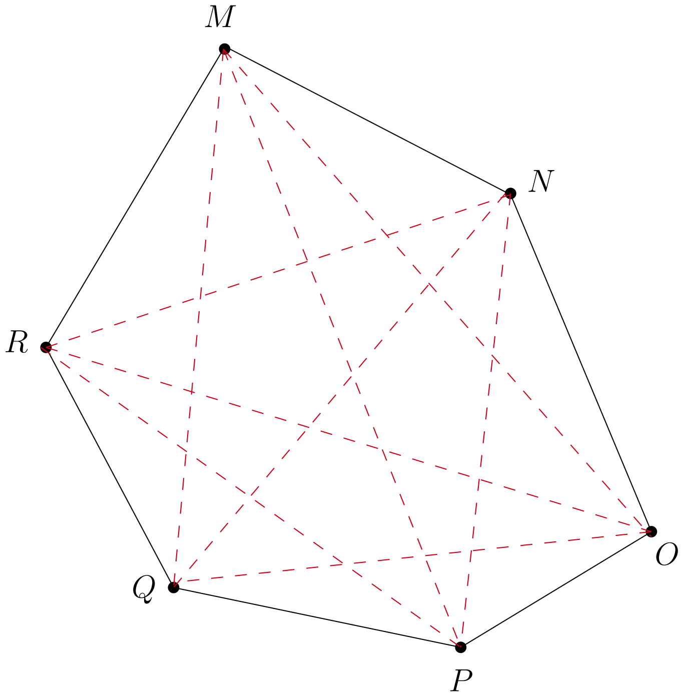

Figure 8.217: **Example of a convex polygon**

With respect to the definitions given above where the diagonals were identified, let us see if there is a relation permitting to know the number of diagonals relatively to the number of edges of a polygon.

For this let us start from a polygon of n sides (also note that it has n vertices):

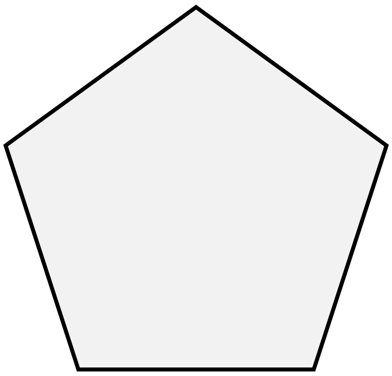

Figure 8.218: **Example of a polygon (pentagon with 5 edges and 5 vertices)**

We define now the total number segments S as equal to the quantity of the sides (edges) E more the quantity of diagonals D such that:

$$S = E + D \tag{8.7.1}$$

With our example we can see that $S = 10$:

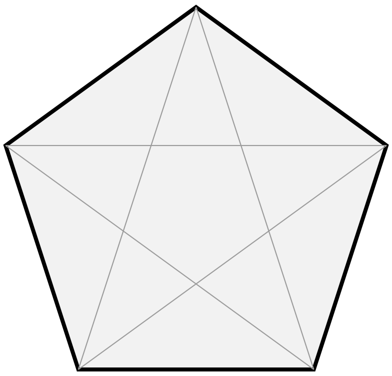

Figure 8.219: **Pentagon with all its 10 segments**

Now take one first point of our pentagon. We see that we can reach all n points (vertices), excepted the chosen one (-1) therefore we can draw $n-1$ segments as shown in the figure below:

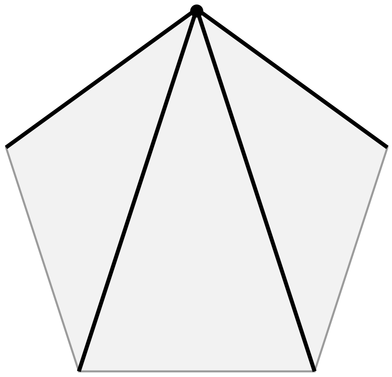

Figure 8.220: Example of segments starting from a chosen point

With the second point, we can also reach all the points n, except the chosen point itself (-1) and we must remove the first point already taken in the previous step (-1). We therefore draw $n-2$ segments:

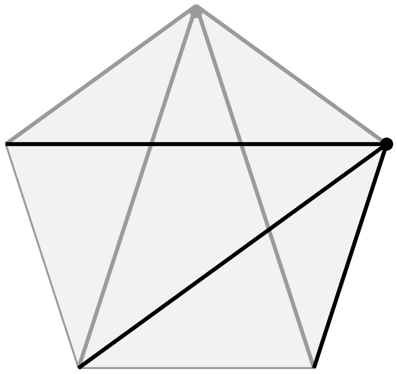

Figure 8.221: Approach with the 2nd point

With the third one, we can also reach all the n points, excepted the considerated point (-1) and less the two points already seen (-2) that is to say the formation of $n-3$ segments:

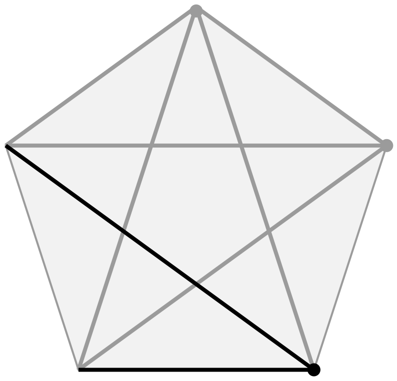

Figure 8.222: Approach with the 3rd point

We continue with the other points: the 4th that gives $n-4$ segments, the fifth that gives $n-5$ segments ... Therefore we see that the $(n-2)$th item thus gives $n-(n-2)$ segments, etc.

So we finally have for:

$$\begin{array}{r@{}l} s &= 1+2+\ldots+(n-2)+(n-1) \\ +s &= (n-1)+(n-2)+\ldots+2+1 \\ \hline 2s &= n+n+\ldots+n+n \end{array} \qquad (8.7.2)$$

By simplifying we find therefore:

$$s=\frac{n(n-1)}{2} \qquad (8.7.3)$$

We find ourselves with two relations:

$$s=\frac{n(n-1)}{2} \quad \text{and} \quad s=n+d \qquad (8.7.4)$$

Therefore it follows that:

$$\boxed{d=s-n=\frac{n(n-1)}{2}-n=\frac{n(n-3)}{2}} \qquad (8.7.5)$$

Definition (#8.7.370): A "regular polygon" is a convex-polygon in which every side has the same length and every angle is the same. For any natural number $n \geq 3$, we can draw a regular polygon with n sides; sometimes we'll name this polygon a "regular n-gon" to emphasize that it has n sides. Below are the regular n-gons for $n=3,4,\ldots,12$. As n gets larger, the regular n-gons look more like a perfect circle:

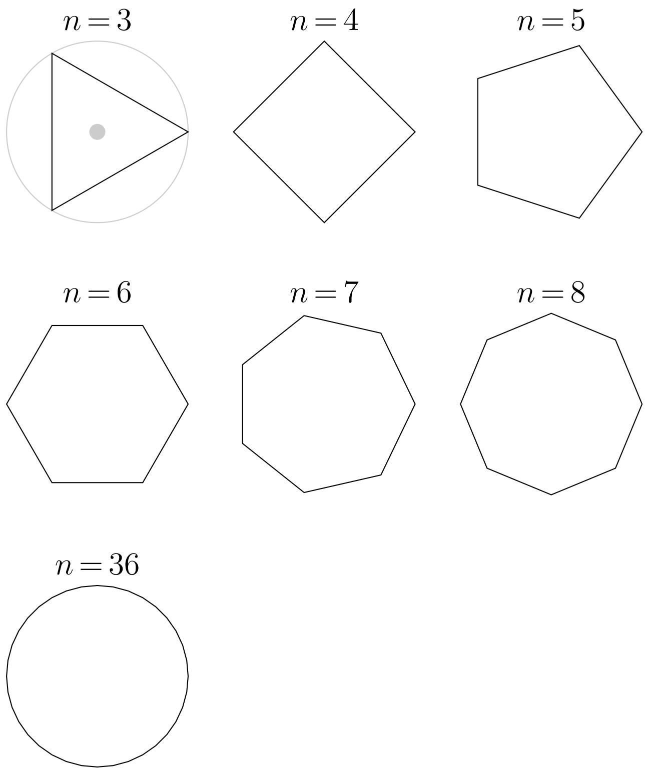

Figure 8.223: **Some regular polygons (subfamily of convex polygons)**

8.7.1.2 Rectangle

Definition (#8.7.371): The "rectangle" is a special case of the quadrangle in the sense that his sides L and H (notation according to length and height as we can see in figure below) are equal in pairs and with right angle (in other words, L is not necessarily equal to H).

Other possible definitions include that a rectangle is a parallelogram with a right angle or a quadrilateral with four right angles...

> **Remark**
>
> The rectangle can be seen as the composition of two (or more) triangles (see below for definition). To build a rectangle, it would be sufficient to have a single rectangle triangle and make him undergo a double reflection and rotation relative to a well-chosen axis (see section Euclidean Geometry page 2640).

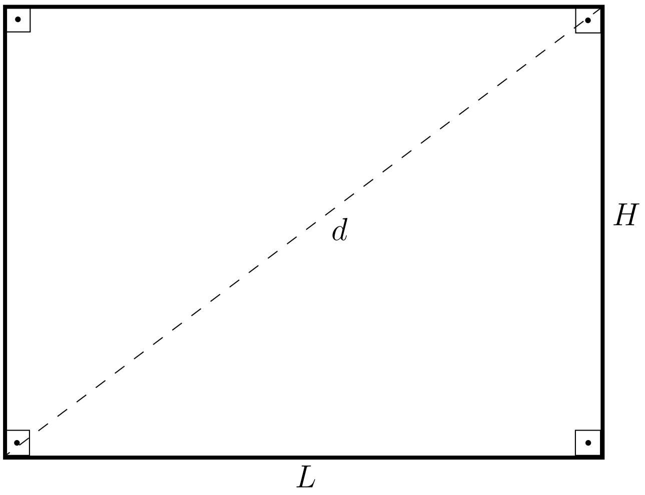

Figure 8.224: **Example of rectangle**

By the Euclid's axioms (see section Euclidean Geometry page 2563), the perimeter of a rectangle is given by:

$$\boxed{P=2(L+H)} \tag{8.7.6}$$

And by definition its surface by:

$$\boxed{S=L\cdot H} \tag{8.7.7}$$

and the length of its diagonal (application of the Pythagorean theorem):

$$d=\sqrt{L^2+H^2} \tag{8.7.8}$$

The position of the rectangle's center of gravity, if we put the Cartesian coordinate system in the lower left corner of this geometry, is trivially given by:

$$G(x,y)=\left(\frac{L}{2},\frac{H}{2}\right) \tag{8.7.9}$$

Finally, indicate that if we were living beings in a two-dimensional space, the rectangle is what we should perceive if a cuboid crossed our universe parallel to its faces.

Finally, let us notice, and without proof, that the sum of the angles or a plane rectangle is equal to $4\cdot\pi/2=2\pi$.

8.7.1.3 Square

Definition (#8.7.372): The "square" is a special case of the rectangle in the sense that its four sides are equal such that $L=H$.

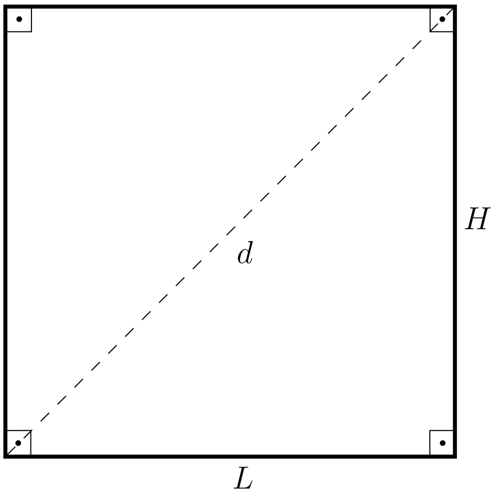

Figure 8.225: **Example of square**

By the Euclid's axioms (see section Euclidean Geometry page 2563), the perimeter of the square is given by:

$$\boxed{P=4L} \tag{8.7.10}$$

So it comes for the surface:

$$\boxed{S=L^2} \tag{8.7.11}$$

and for its diagonal:

$$d=\sqrt{L^2+H^2}=\sqrt{L^2+L^2}=\sqrt{2L^2}=\sqrt{2}L \tag{8.7.12}$$

The position of the square's center of gravity, if put the Cartesian coordinate system in the lower left corner of the form, is trivially given by:

$$G(x,y)=\left(\frac{L}{2},\frac{L}{2}\right) \tag{8.7.13}$$

Finally, let us indicate that if we were living beings in a two-dimensional space, the square is what we should perceive if a cube crossed our universe parallel to its faces.

Also notice, and without proof, that the sum of the angles or a plane square is equal to $4\cdot\pi/2=2\pi$.

8.7.1.4 Unspecified Triangle

Definition (#8.7.373): An "unspecified triangle" is a polygon with three sides and includes in particular cases the: isosceles, equilateral and rectangles triangles. A triangle with vertices A, B, and C is denoted $\triangle ABC$.

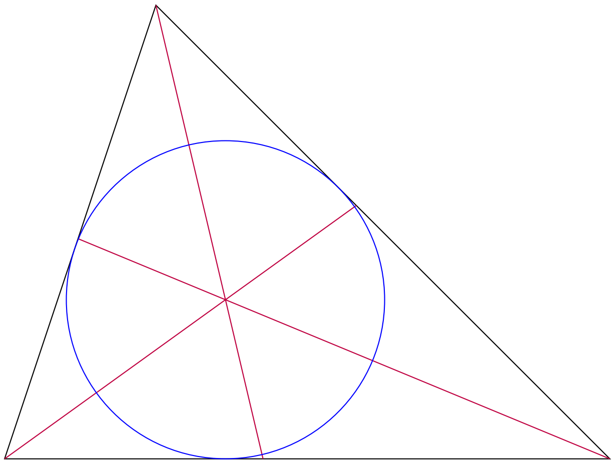

Figure 8.226: **Example of an unspecified triangle with inscribed circle and bisectors**

Remark

For the details about the Circumcircles and Incircles of triangles we send the reader to the section of Euclidean Geometry (see page 2620).

By the Euclid's axioms (see section Euclidean Geometry page 2563), the perimeter of an unspecified triangle is given by:

$$\boxed{P=a+b+c} \tag{8.7.14}$$

An unspecified plane triangle can always be decomposed into two right angle triangles. Thus, the one of the above figure can be divided into two right angle triangles:

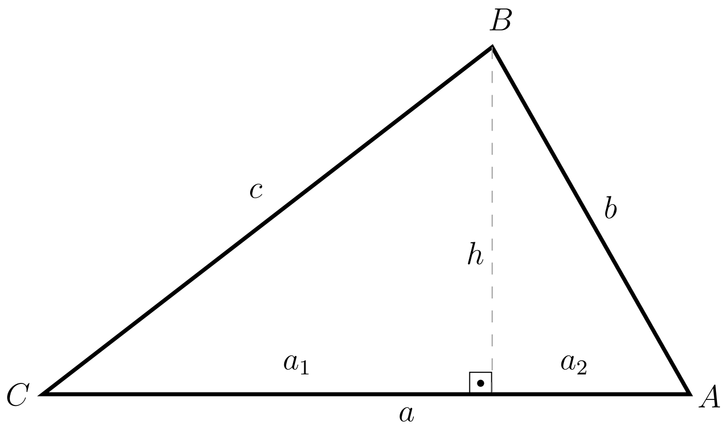

Figure 8.227: **Unspecified triangle divided into two right triangles**

of respective basis a_1 and a_2 (defined by the orthogonal projection of the top on opposite to the segment a) such as:

$$a = a_1 + a_2 \tag{8.7.15}$$

The surface of each of these two right angle triangles is as we have said already implicitly in our study of the rectangle, half the area of a rectangle of the same length and same height. Therefore:

$$S_1 = \frac{a_1 h}{2} \qquad S_2 = \frac{a_2 h}{2} \tag{8.7.16}$$

Therefore, the sum of these surfaces, gives us the surface of unspecified triangle:

$$\boxed{S_{\triangle} = S_1 + S_2 = \frac{a_1 h}{2} + \frac{a_2 h}{2} = \frac{a_1 + a_2}{2} h = \frac{ah}{2}} \tag{8.7.17}$$

We can say from this latter equality that the surface of any one triangle is similar to the half of the area of a rectangle of length $L = a$ and height $H = h$.

Remark

Whatever the basis a, b, c and the respective height h_a, h_b, h_c, the previous reasoning remains of course completely correct.

That said ... it is nice and pretty but there are very many practical cases where we do not know the height but only the length of the three sides. So, what do we do? Well, we will use the cosine theorem (Al-Kashi's Theorem) proved in the section Trigonometry (see page 2544) which gives us a reminder for any unspecified triangle of the type:

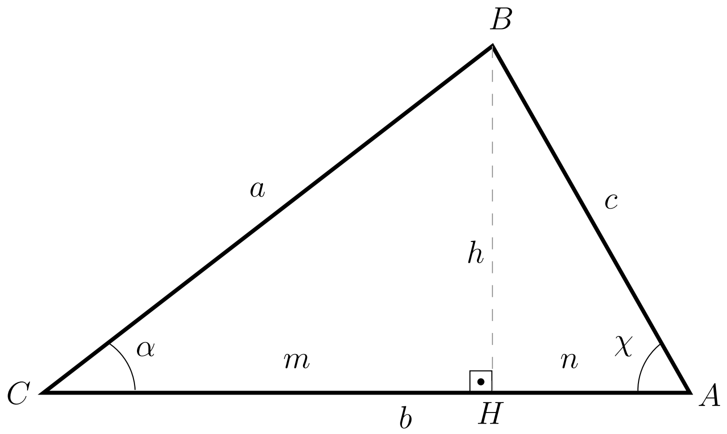

Figure 8.228: **Reminder of the construction for the cosine's theorem proof**

$$\cos(\chi) = \frac{b^2 + c^2 - a^2}{2bc} \tag{8.7.18}$$

and also the relation resulting in the triangle relative to the surface:

$$S = \frac{bh}{2} = \frac{bc\cos\left(\pi - \frac{\pi}{2} - \chi\right)}{2} = \frac{bc\cos\left(\frac{\pi}{2} - \chi\right)}{2} = \frac{bc\sin(\chi)}{2} \tag{8.7.19}$$

Therefore we have:

$$\begin{aligned}S&=\frac{bc\sqrt{1-\cos^2(\chi)}}{2}=\frac{bc\sqrt{(1-\cos(\chi))(1+\cos(\chi))}}{2}\\&=\frac{bc}{2}\sqrt{\left(1-\frac{b^2+c^2-a^2}{2bc}\right)\left(1+\frac{b^2+c^2-a^2}{2bc}\right)}\\&=\frac{bc}{2}\sqrt{\frac{1}{4b^2c^2}(2bc-b^2-c^2+a^2)(2bc+b^2+c^2-a^2}\\&=\frac{1}{4}\sqrt{(-(b-c)^2+a^2)\left((b+c)^2-a^2)\right)}=\frac{1}{4}\sqrt{(a^2-(b-c)^2)\left((b+c)^2-a^2\right)}\\&=\frac{1}{4}\sqrt{((a+b-c)(a-b+c))\left((b+c+a)(b+c-a)\right)}\end{aligned}\tag{8.7.20}$$

Therefore after rearrangement we get finally:

$$\boxed{S=\frac{1}{4}\sqrt{(a+b+c)(b+c-a)(a+b-c)(a-b+c)}}\tag{8.7.21}$$

Relation that is commonly named "Heron's formula" also sometimes named "Hero's formula" most know in the following form when we put $\Sigma:=\dfrac{1}{2}(a+b+c)$:

$$\begin{aligned}S&=\sqrt{\frac{1}{16}(a+b+c)(b+c-a)(a-b+c)(a+b-c)}\\&=\sqrt{\left(\frac{a+b+c}{2}\right)\left(\frac{b+c-a}{2}\right)\left(\frac{a-b+c}{2}\right)\left(\frac{a+b-c}{2}\right)}\\&=\sqrt{\Sigma\left(\Sigma-a\right)\left(\Sigma-b\right)\left(\Sigma-c\right)}\end{aligned}\tag{8.7.22}$$

The determination of the center of gravity (or centroid) G (see section Euclidean Geometry page 2635) is a little less intuitive than in the case of the rectangle...

Theorem 8.24. Given a triangle $\triangle ABC$. We name A' the "middle of the segment" $\overline{BC}$, B' that of $\overline{AC}$ and C' that of $\overline{AB}$:

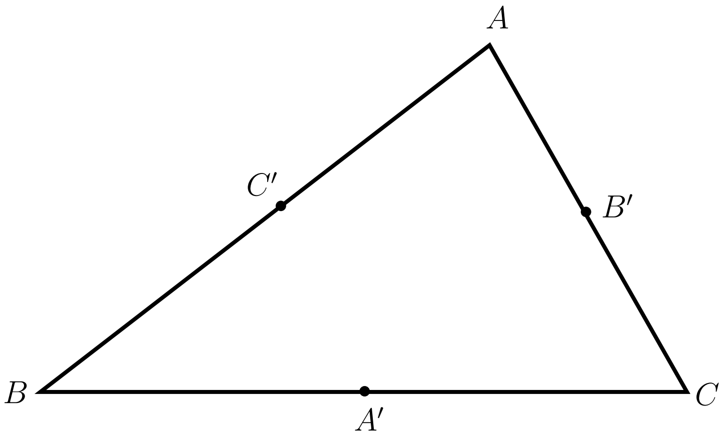

Figure 8.229: **Starting point for determining the center of gravity**

We will prove that only the point G satisfying (see section Euclidean Geometry):

$$\overrightarrow{GA}+\overrightarrow{GB}+\overrightarrow{GC}=\vec{0}\tag{8.7.23}$$

is the point of intersection of the three medians of triangle $\triangle ABC$. This proof will be made two stages: two proposals (at the end, we can conclude by the theorem):

P1. If $\triangle ABC$ is a triangle then there exists one and only one center of gravity G such that $\overrightarrow{GA}+\overrightarrow{GB}+\overrightarrow{GC}=\vec{0}$.

Proof 8.24.1. Let G be a point in the plane such as $\overrightarrow{GA}+\overrightarrow{GB}+\overrightarrow{GC}=\vec{0}$. Then we can write that:

$$\overrightarrow{GA}+\underbrace{\overrightarrow{GA}+\overrightarrow{AB}}_{\overrightarrow{GB}}+\underbrace{\overrightarrow{GA}+\overrightarrow{AC}}_{\overrightarrow{GC}}=\vec{0} \tag{8.7.24}$$

Therefore:

$$\overrightarrow{AG}=\frac{1}{3}\left(\overrightarrow{AB}+\overrightarrow{AC}\right) \tag{8.7.25}$$

This vector equality ensures that the G point is unique and we can even move it by moving the edges of the triangle!

■ Q.E.D.

P2. The three medians of a triangle are concurrent. Their intersection is the point G.

Proof 8.24.2. To prove that the three medians are concurrent, we will prove that G belongs to each of the three medians.

Just before we proved G satisfies the equality:

$$\overrightarrow{AG}=\frac{1}{3}\left(\overrightarrow{AB}+\overrightarrow{AC}\right) \tag{8.7.26}$$

As A' is the midpoint of $\overline{BC}$, then we can write that:

$$\overline{AB}+\overline{AC}=2\overline{AA'} \tag{8.7.27}$$

Therefore we get:

$$\overrightarrow{AG}=\frac{1}{3}\left(\overrightarrow{AB}+\overrightarrow{AC}\right)=\frac{1}{3}\left(2\overrightarrow{AA'}\right)=\frac{2}{3}\overrightarrow{AA'} \tag{8.7.28}$$

The vectors $\overrightarrow{AG}$ and $\overrightarrow{AA'}$ are collinear! Therefore the points A, G, A' are aligned. Writing in an other way, the point G is part of the median $\overline{AA'}$ of the triangle $\triangle ABC$. We can even say that is placed at the two thirds of the segment $\overline{AA'}$ from the top A.

What we have just shown with the median AA' is of course also true for the other two medians. Therefore:

$$\begin{gathered}\overrightarrow{AG}=\frac{2}{3}\overrightarrow{AA'}\\ \overrightarrow{BG}=\frac{2}{3}\overrightarrow{BB'}\\ \overrightarrow{CG}=\frac{2}{3}\overrightarrow{CC'}\end{gathered} \tag{8.7.29}$$

To resume, the point G is therefore part of the three medians $\overline{AA'}$, $\overline{BB'}$ and $\overline{CC'}$. These three lines are concurrent and the point G is the intersection point. This result will be useful later in our study of polyhedra.

■ Q.E.D.

Finally, let us indicate that if we were living beings in a two-dimensional space, the triangle is what we should perceive if geometric shapes composed of at least three joined sides would cross our universe through one of its vertex.

Also let us recall that the sum of the angles of any plane triangle is equal to π (180°) as proved in the section of Euclidean Geometry page 2593.

We will stop here this analogy with a two-dimensional space that can be generalized to each geometric shape that we present thereafter (circle and sphere, ellipse and ellipsoid, etc.). The idea was mainly to present the conception that volumes we experience in our daily lives can also be seen as 4-dimensional space shapes crossing our 3-dimensional space.

8.7.1.5 Isosceles Triangle

Definition (#8.7.374): An "isosceles triangle" is a triangle that has two sides of equal length. Sometimes it is specified as having two and only two sides of equal length, and sometimes as having at least two sides of equal length, the latter version thus including the equilateral triangle as a special case.

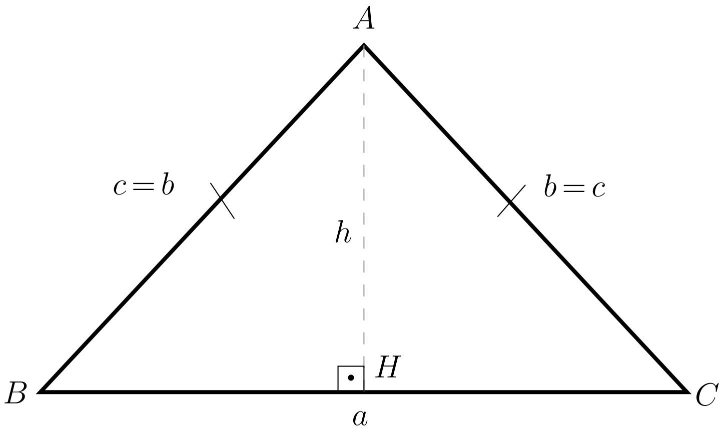

Figure 8.230: **Example of isosceles triangle**

In an isosceles triangle, the two equal sides are named "legs", and the remaining side is named the "base". The opposite angle to the base is named the "vertex angle", and the point associated with that angle is named the "apex". The two equal angles are named the "isosceles angles".

The perimeter of such a triangle remains:

$$\boxed{P = a + b + c} \quad (8.7.30)$$

but as it has two equal sides, then we can always simplify as follows:

$$P = a + b + b = a + 2b = a + 2c \quad (8.7.31)$$

The surface as we have proved above in the general case remains:

$$\boxed{S=\frac{ah}{2}} \tag{8.7.32}$$

And if we don't know the height but we know the internal angles we can by apply elementary trigonometry if needed (see section Trigonometry page 2508).

And the center of gravity remains, as we have proved in the general case (unspecified triangle), at the position:

$$\begin{aligned}\overrightarrow{AG}&=\frac{2}{3}\overrightarrow{AA'}\\ \overrightarrow{BG}&=\frac{2}{3}\overrightarrow{BB'}\\ \overrightarrow{CG}&=\frac{2}{3}\overrightarrow{CC'}\end{aligned} \tag{8.7.33}$$

A remarkable property of an isosceles triangle is that the bisector and the median of the third side, that is of not equal size than the two others, are not-distinguishable and therefore obviously of equal length (see section Euclidean Geometry page 2607).

A famous isosceles triangle is the right angle isosceles triangle because its angles are canonical and we get immediately $\theta=\pi/4$ and also we have immediately the length of the hypotenuse by applying the Pythagorean theorem:

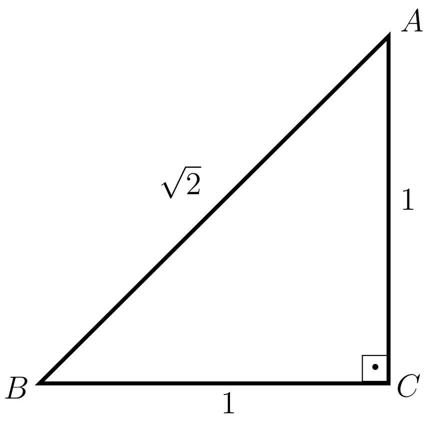

Figure 8.231: **Right angle isosceles triangle**

Also let us recall that the sum of the angles of any plane triangle is equal to π (180°) as proved in the section of Euclidean Geometry page 2593.

8.7.1.6 Equilateral Triangle

Definition (#8.7.375): An "equilateral triangle" is a triangle in which all three sides are equal. In the familiar Euclidean geometry, equilateral triangles are also "equiangular"; that is, all three internal angles are also congruent to each other and are each equal to $\pi/3$. They are regular polygons, and can therefore also be referred to as regular triangles.

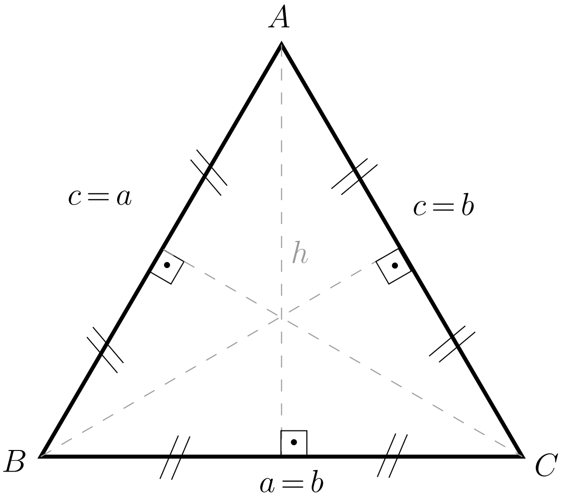

Figure 8.232: **Equilateral triangle**

Theorem 8.25. Each angle of an equilateral triangle is $\pi/3$ [rad] (60°).

Proof 8.25.1. First let us recall that by the angle sum theorem (page 2593) we have:

$$\hat{A}+\hat{B}+\hat{C}=\pi \tag{8.7.34}$$

We know also that Δabc is equilateral, then:

$$a=b=c \tag{8.7.35}$$

Then as $\angle\overline{ab}$ and $\angle\overline{ac}$ are congruent, we have:

$$\hat{A}=\hat{B} \tag{8.7.36}$$

And proceeding identically:

$$\hat{B}=\hat{C} \tag{8.7.37}$$

and:

$$\hat{C}=\hat{A} \tag{8.7.38}$$

Hence we can write that:

$$\hat{\theta}:=\hat{A}=\hat{B}=\hat{C} \tag{8.7.39}$$

And using the angle sum theorem:

$$\hat{A}+\hat{B}+\hat{C}=\pi=3\theta \tag{8.7.40}$$

We get:

$$\theta=\frac{\pi}{3} \tag{8.7.41}$$

■ Q.E.D.

The perimeter of such a triangle remains:

$$P=a+b+c \tag{8.7.42}$$

but as it has three equal sides, then we can always simplify as follows:

$$\boxed{P=3a=3b=3c} \tag{8.7.43}$$

The surface as we have proved above in the general case remains:

$$\boxed{S=\frac{ah}{2}} \tag{8.7.44}$$

Applying Pythagorean theorem we get if we don't know h:

$$S=\frac{a}{2}h=\frac{a}{2}\sqrt{a^2-\left(\frac{1}{2}a\right)^2}=\frac{a^2}{2}\sqrt{1-\frac{1}{4}}=\frac{a^2}{2}\sqrt{\frac{3}{4}}=\frac{\sqrt{3}}{4}a^2 \tag{8.7.45}$$

It can be shown that a triangle with given perimeter has the maximum possible area, if it is equilateral.

Proof 8.25.2. Remember the Heron's formula proved above ($\Sigma=\dfrac{1}{2}(a+b+c)$):

$$S=\sqrt{\Sigma\left(\Sigma-a\right)\left(\Sigma-b\right)\left(\Sigma-c\right)} \tag{8.7.46}$$

To find the conditions for the maximum area, we want to compute derivatives with respect a, b and c but since they are not independent variables, we first substitute the semi-perimeter Σ into Heron's equation to get rid of one degree of freedom:

$$c=2\Sigma-a-b \tag{8.7.47}$$

Therefore:

$$S=\Sigma(\Sigma-a)(\Sigma-b)(a+b-\Sigma) \tag{8.7.48}$$

Setting the derivative with respect to a to zero:

$$\begin{aligned}\frac{\mathrm{d}S}{\mathrm{d}a}&=\frac{1}{2}\frac{-\Sigma(\Sigma-b)(a+b-\Sigma)+\Sigma(\Sigma-a)(\Sigma-b)}{\sqrt{\Sigma\left(\Sigma-a\right)\left(\Sigma-b\right)\left(\Sigma-c\right)}}\\&=\frac{-\Sigma(\Sigma-b)(a+b-s)+\Sigma(\Sigma-a)(\Sigma-b)}{2S}\\&=\frac{\Sigma(\Sigma-b)(2\Sigma-2a-b)}{2S}=0\\&\Rightarrow 2\Sigma-2a-b=0\end{aligned} \tag{8.7.49}$$

Since $b=\Sigma$ is not a solution $A\neq 0\Rightarrow b\neq\Sigma$.

Similarly, setting the derivative with respect to b to zero yields:

$$2\Sigma-2b-a=0 \tag{8.7.50}$$

Solving simultaneously gives:

$$a=b=\frac{2\Sigma}{3} \tag{8.7.51}$$

and substituting back gives:

$$c=\frac{2\Sigma}{3} \tag{8.7.52}$$

So $a=b=c$ and the triangle is equilateral.

■ Q.E.D.

And the center of gravity remains, as we have proved in the general case (unspecified triangle), at the position:

$$\begin{gathered}\overrightarrow{AG}=\frac{2}{3}\overrightarrow{AA'}\\ \overrightarrow{BG}=\frac{2}{3}\overrightarrow{BB'}\\ \overrightarrow{CG}=\frac{2}{3}\overrightarrow{CC'}\end{gathered} \tag{8.7.53}$$

A remarkable property of an equilateral triangle is that all its bisectors and medians are non-distinguishable and obviously of the same length (see section Euclidean Geometry page 2607)!

Let us now see the important little "Viviani's theorem" regularly used for graphical representation in the field of materials engineering (mixture), or statistics (mixture designs or distribution of three frequencies of data whose sum is always equal).

Consider the following figure:

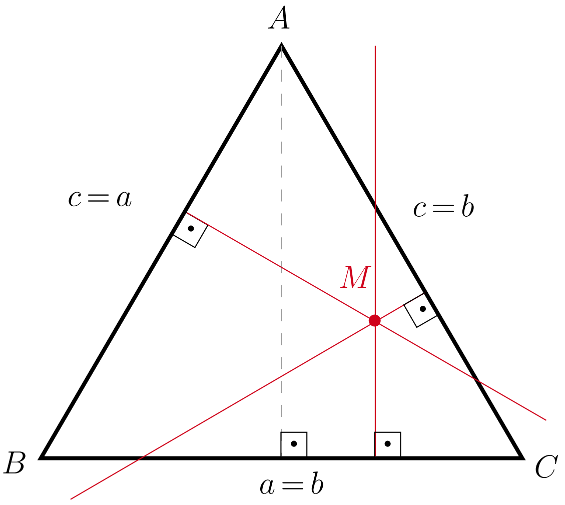

Figure 8.233: **Illustrative figure for Viviani's theorem**

Theorem 8.26. If we place a point in an equilateral triangle and that from this point we draw a line in the direction of each side, so that the lines are perpendicular to each side. No matter where we place the point, the sum of the perpendicular distances between the point and the sides is equal to the height of the triangle!

Proof 8.26.1. For the proof, let us denote by d_a, d_b, d_c the distances M to the sides, the length of one side and the height h. Then we have:

$$\frac{lh}{2} = S_{\Delta ABC} = S_{MBC} + S_{MCA} + S_{MAC} = \frac{ld_a}{2} + \frac{ld_b}{2} + \frac{ld_c}{2} = \frac{l(d_a + d_b + d_c)}{2} \tag{8.7.54}$$

and we have therefore well:

$$h = d_a + d_b + d_c \tag{8.7.55}$$

■ Q.E.D.

Also let us recall that the sum of the angles of any plane triangle is equal to π (180°) as proved in the section of Euclidean Geometry page 2593.

8.7.1.7 Right Triangle

Definition (#8.7.376): A "right triangle" (American English) or "right-angled triangle" (British English) is a triangle in which one angle is a right angle (that is, a $\pi/2$-radian angle). The relation between the sides and angles of a right triangle is the basis for trigonometry (see corresponding section).

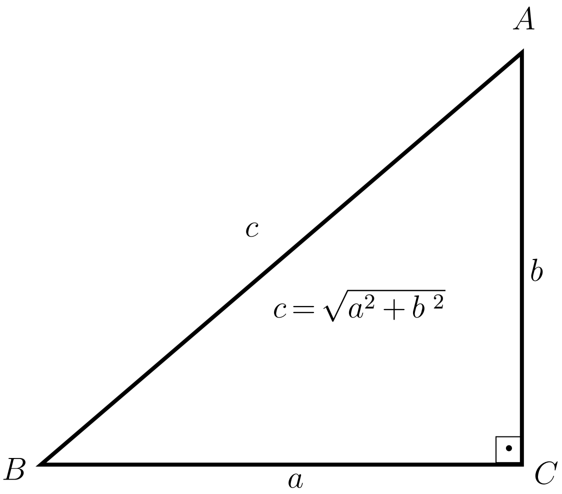

Figure 8.234: **Example of a right angle triangle**

The side opposite to the right angle is named the "hypotenuse".

The perimeter of such a triangle remains:

$$\boxed{P = a + b + c = a + b + \sqrt{a^2 + b^2}} \tag{8.7.56}$$

The surface as we have proved above in the general case remains:

$$\boxed{S = \frac{ah}{2} = \frac{ab}{2}} \tag{8.7.57}$$

And the center of gravity remains, as we have proved in the general case (unspecified triangle), at the position:

$$\begin{aligned}\overrightarrow{AG} &= \frac{2}{3}\overrightarrow{AA'}\\ \overrightarrow{BG} &= \frac{2}{3}\overrightarrow{BB'}\\ \overrightarrow{CG} &= \frac{2}{3}\overrightarrow{CC'}\end{aligned} \tag{8.7.58}$$

Remarkable property of a right triangle: this triangle has this unique property that we can directly apply to it the Pythagorean theorem (see section Euclidean Geometry page 2609).

Also let us recall that the sum of the angles of any plane triangle is equal to π (180°) as proved in the section of Euclidean Geometry page 2593.

8.7.1.8 Trapezoid

Definition (#8.7.377): A convex quadrilateral with at least one pair of parallel sides is referred to as a "trapezoid" in American and Canadian English but as a "trapezium" in English outside North America. The parallel sides are named the "bases" of the trapezoid and the other two sides are named the "legs" or simply the "lateral sides" (if they are not parallel; otherwise there are two pairs of bases). A "scalene trapezoid" is a trapezoid with no sides of equal length.

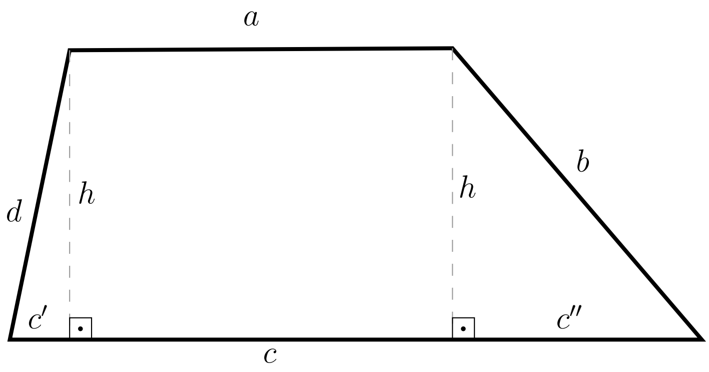

Figure 8.235: **Example of trapezoid**

Calculating the perimeter of the trapezoid is obvious:

$$\boxed{P = a + b + c + d} \tag{8.7.59}$$

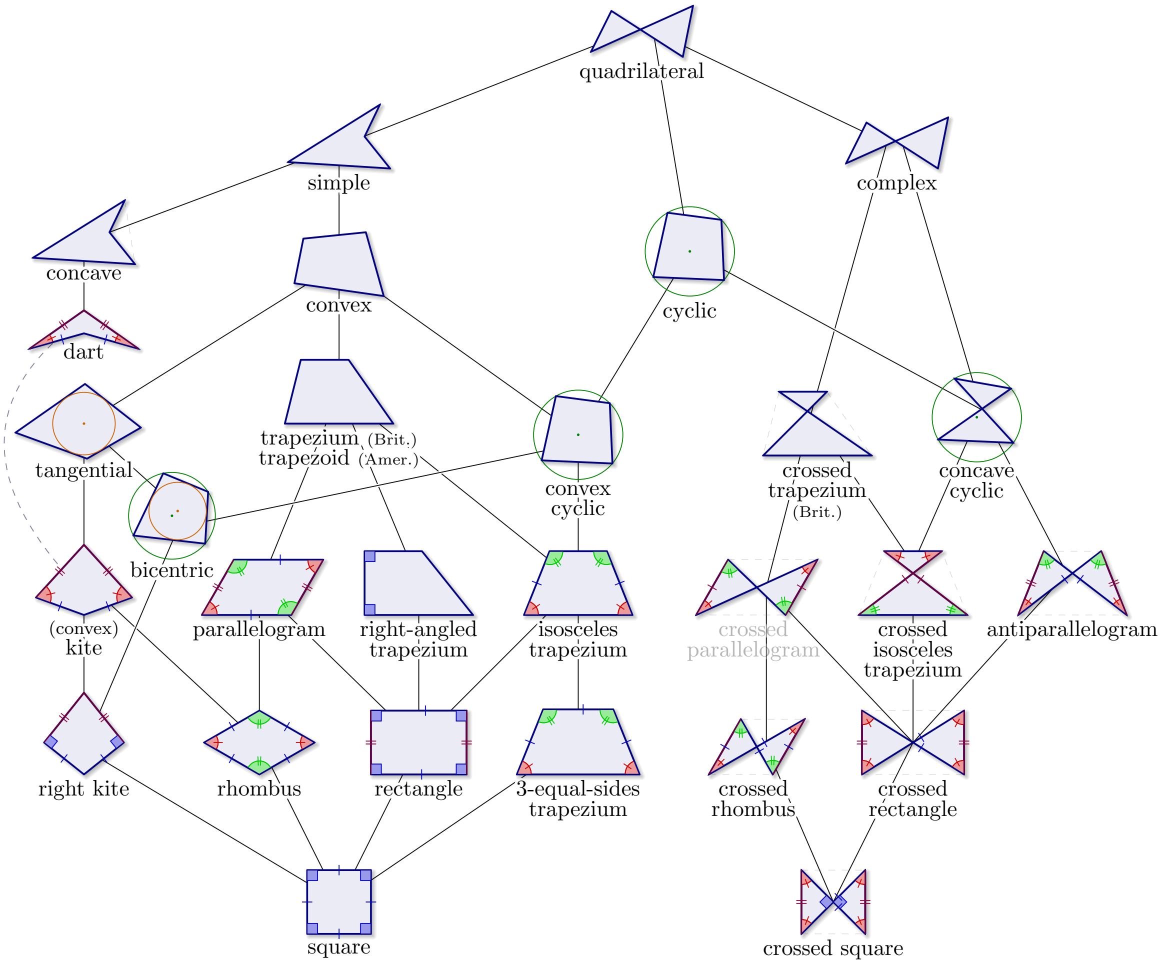
Its surface is calculated using the decomposition:

$$\begin{aligned}S &= \frac{c'h}{2} + ah + \frac{c''h}{2} = \frac{(c'+c''+2a)h}{2} = \frac{(c'+c''+a+a)h}{2}\\ &= \frac{(c'+c''+a+(c-c'-c''))h}{2} = \frac{(a+c)h}{2}\end{aligned} \tag{8.7.60}$$

Finally:

$$\boxed{S = \frac{(a+c)h}{2}} \tag{8.7.61}$$

When both sides have the same length, we get the special cases of the square, the rectangle, of the rhombus or of the parallelogram (here we put the order from more specific to the more general, we could put the diamond rhombus as n°2):



quadrilateral
simple
complex
concave
convex
cyclic
dart
tangential
trapezium (Brit.)
trapezoid (Amer.)
convex
cyclic
crossed
trapezium
(Brit.)
concave
cyclic
bicentric
(convex)
kite
parallelogram
right-angled
trapezium
isosceles
trapezium
crossed
parallelogram
crossed
isosceles
trapezium
antiparallelogram
right kite
rhombus
rectangle
3-equal-sides
trapezium
crossed
rhombus
crossed
rectangle
square
crossed square

Figure 8.236: **Quadrilateral hierarchy including Trapezoid classification (author: Izaak Neutelings)**

Also a common use is to retain a more restrictive definition, in order to not take into account these particular figures. We add in this case that the lengths of two parallel sides are not equal (this allows students of high-school classes to avoid confusion arising from the existence of two names for the same object, such as rhombus and trapezius).

Remark

There is a particular case of the trapezoid, the "isosceles trapezoid" as we can see on the previous figure, whose two non-parallel sides are the same length (we can add: as both sides are not parallel, it is not a parallelogram).

8.7.1.9 Parallelogram

Definition (#8.7.378): The "parallelogram" is a special case of the quadrilateral and very important (in the context of the analysis of shapes in physics), where the sides are parallel in pairs and of opposite equal angles (opposite angles are congruent):

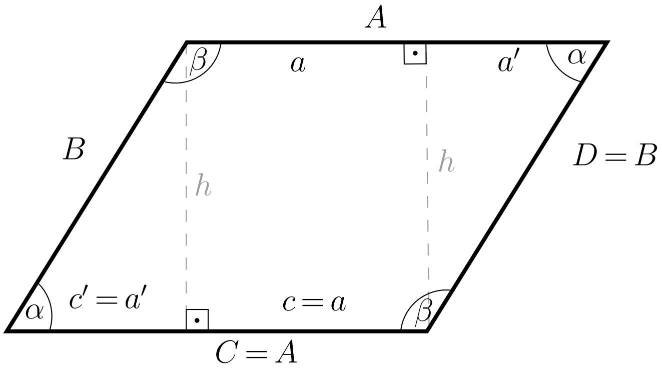


Figure 8.237: **Parallelogram example**

The rhombus being a special case of the parallelogram as we already know (the rhombus is a parallelogram with all sides equal)!

The perimeter of the parallelogram is obviously given by:

$$\boxed{P=a+a+b+b=2a+2b=2(a+b)} \tag{8.7.62}$$

For the surface, as this is a special case of the trapezoid, it comes immediately (as we will use only this relation in the book we will not prove other method to calculate the surface):

$$\boxed{S=\frac{(A+A)h}{2}=Ah} \tag{8.7.63}$$

Given the above figure, it is clear that if we cut the parallelogram into two as below, we see that this is twice the same triangle:

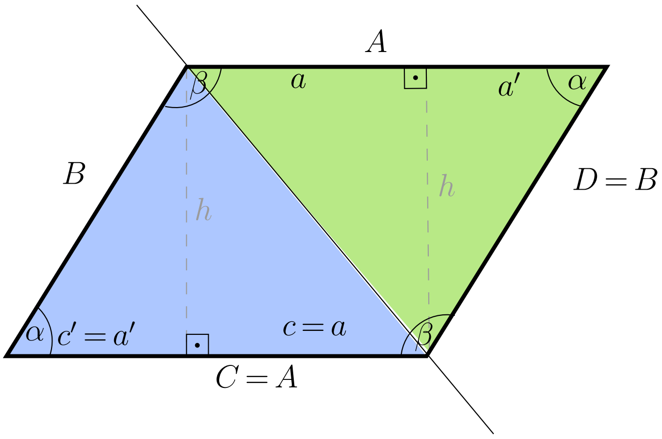

Figure 8.238: **Cutted parallelogram**

Thanks to this we will have a very useful property for the physical analysis of the static forces or phasors in the studies of the wave superposition (see section Wave Mechanics page ??).

Remark

As we already know parallelograms are therefore trapezoids like (see classification figure above for a refresh).

Also let us recall that as the sum of the angles of any plane triangle is equal to π (180°) as proved in the section of Euclidean Geometry page 2593, and that a parallelogram is made of two identical triangle, the sum of the angles of a parallelogram is then equal to 2π.

8.7.1.10 Hexagon

The hexagon is a quite interesting case. Indeed, is used for satellite signal Earth tiling and also because the "Honeycomb conjecture" states that the hexagonal tiling is the best way to divide a surface into regions of equal area with the least total perimeter.

This structure exists naturally in the form of graphite, where each sheet of graphene resembles chicken wire, with strong covalent carbon bonds. Tubular graphene sheets have been synthesised. These are known as "carbon nanotubes". They have many potential applications, due to their high tensile strength and electrical properties. Silicene is similar.

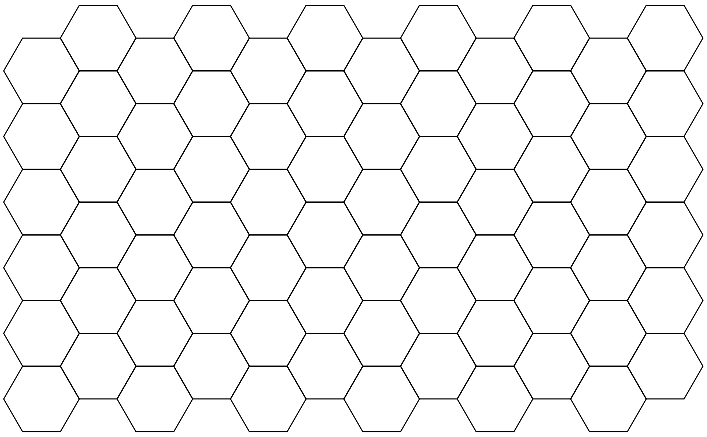

Figure 8.239: **A regular hexagonal grid**

Some applications (the reader can also take a look about the European Extra Large Telescope):

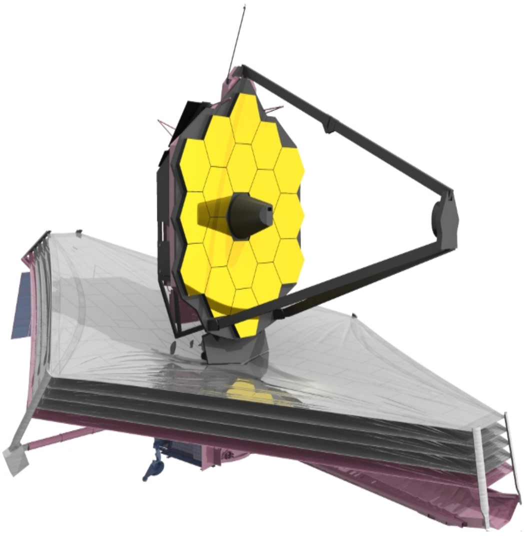

Figure 8.240: James Webb Space Telescope

Figure 8.241: TV broadcast reflector antenna

The study of the geometrical properties of the hexagon is also useful to study the "22° Sun hallo effect" and also the "Sun dog effect" (see section Geometric Optics page 4385).

Definition (#8.7.379): In geometry, a hexagon is a 6-sided polygon or 6-gon. The total of the internal angles of any hexagon is 4π. A "regular hexagon" is defined as a hexagon that is both equilateral and equiangular.

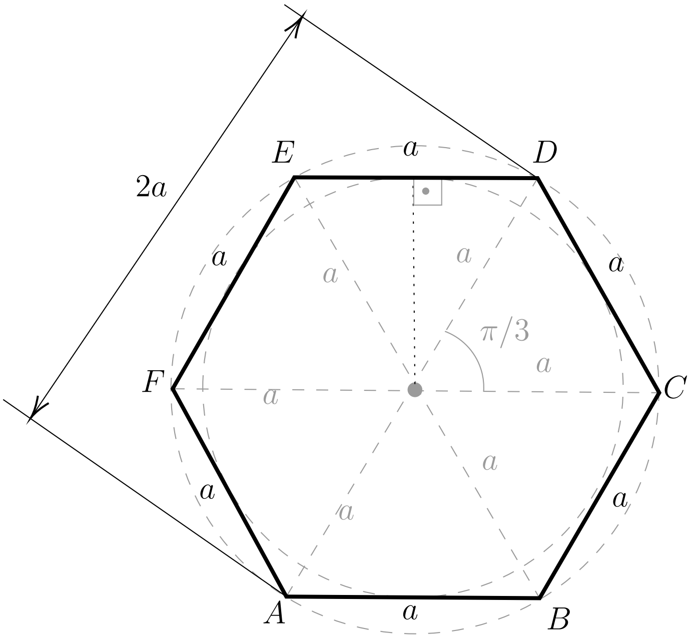

Figure 8.242: Regular hexagon details (source: Wikipedia)

First the perimeter is obviously:

$$\boxed{P=6a} \tag{8.7.64}$$

The surface of a regular hexagon of side length a is obviously given by:

$$S=6\left(\frac{1}{2}a(a\tan\left(\frac{\pi}{6}\right))\right)=3a^2\frac{\sqrt{3}}{2}=\frac{\sqrt{27}}{2}a^2 \tag{8.7.65}$$

Therefore:

$$\boxed{S=\frac{\sqrt{27}}{2}a} \tag{8.7.66}$$

Now let us come back to our honeycomb conjecture!

To begin our search, we had three ideas: the structure of the honeycomb cells should be strong, stable and economical.

The cells are solid if they can be nested and leave no holes. We are therefore interested in tiling.

It can be considered as intuitive that all cells must have the same form and that they will be stable if their form is regular. So we will study the regular polygons.

Let us recall that regular polygon is a geometric figure that has all sides of the same length and all angles of equal measure.

Of all the regular polygons, we have sought those who realize a tiling.

This problem is like looking how it is possible to assemble identical regular polygons around its edges.

For our study, we need to know two things:

1. The sum of the measures of the three angles of a planar triangle is equal to π
2. A round is equal to 2π

Let us try with different shapes:

1. Equilateral triangles ($\pi/3$)

   The three corners of an equilateral triangle are equal, and their measurement is $\pi/3=$. And as $6\cdot(\pi/2)=2\pi$, we can assembled six equilateral triangles around the vertices and thus realize a tiling:

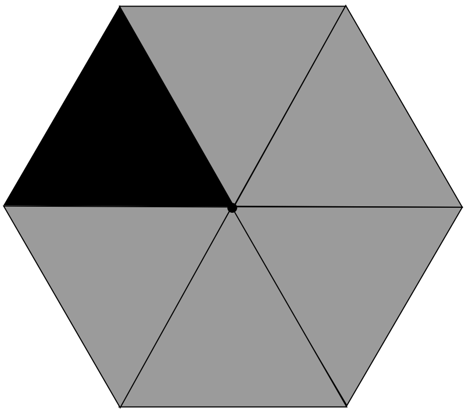

Figure 8.243: **Equilateral Triangle Tiling**

2. Squares $(2\pi/4)$

   The corners angles of a square measure $\pi/2$. And as $4\cdot(\pi/2)=2\pi$, we can assembled four square around the vertices and so achieve a tiling:

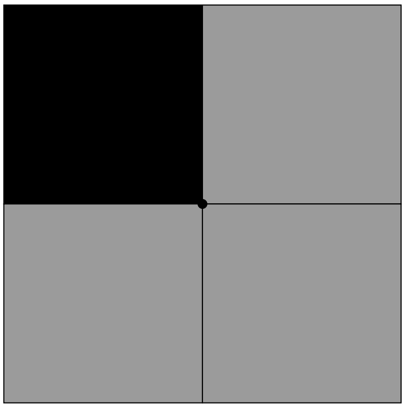

Figure 8.244: **Square Tiling**

3. Regular pentagons $(2\pi/5)$

   The internal angles of a regular pentagon is equal to $2\pi/5$ therefore the internal vertices angles are equal to $\pi-2\pi/5=3\pi/5$.

   If we assembled three of theme around a node this gives holes as $3\cdot(3\pi/5)<2\pi$, and obviously add one more pentagon will not solve the problem!

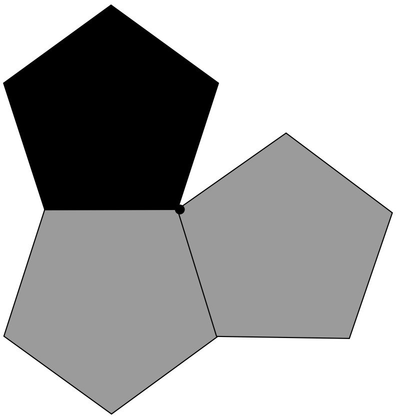

Figure 8.245: **Pentagon Tiling**

We therefore can not provide a tiling with pentagons.

4. Regular hexagons ($2\pi/6$)

   The internal angles of a regular pentagon is equal to $2\pi/6$ therefore the internal vertices angles are equal to $\pi-2\pi/6=2\pi/3$.

   And as $3\cdot(2\pi/3)=2\pi$, we can assemble three regular hexagons around the vertices and so achieve a tiling:

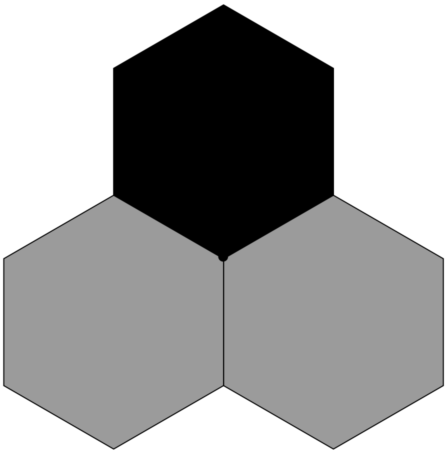

Figure 8.246: **Hexagon Tiling**

5. Regular polygons with seven sides and more

   From polygon with seven sides and more, tiling is impossible because the internal angles are not integer dividers from 2π.

The general relation to get the measurement of the angles of a regular polygon with n sides is:

$$\pi-\left(\frac{2\pi}{n}\right) \tag{8.7.67}$$

Therefore, the only regular polygons that realize a tiling are equilateral triangles, squares and regular hexagons!!

Finally, we thought that bees must use the least amount of wax to make their cells, while having the maximum space inside.

Therefore the question is: Among the equilateral triangle, the square and the regular hexagon, which he has the greatest area for the smallest perimeter?

In other word we seek to maximize the ratio A/P (or the smallest ratio P/A).

So we have for each shape using our previous results:

1. Equilateral triangle:

$$\frac{A}{P}=\frac{\dfrac{1}{2}bh}{3b}=\frac{1}{6}h=\frac{1}{6}b\tan(\pi/6)=\frac{1}{6}b\frac{\sqrt{3}}{3}b\cong\frac{\sqrt{3}}{18}b\cong 0.0962b \tag{8.7.68}$$

2. Square:

$$\frac{A}{P}=\frac{b^2}{4b}=\frac{b}{4}=0.25b \tag{8.7.69}$$

3. Regular hexagon:

$$\frac{\frac{\sqrt{27}}{2}b^2}{6b}=\frac{\sqrt{27}}{12}b=\frac{\sqrt{3}}{3}b\cong 0.5773b \tag{8.7.70}$$

Among the equilateral triangle, the square and the regular hexagon it is therefore the regular hexagon which gives for the maximum ratio "area on perimeter".

So that the cell structure is solid, stable and economical, bees are incentive to build basic regular hexagons. We can see that this is what they do naturally (after a lot of trial and errors during their evolution)!

8.7.1.11 Rhombus

Definition (#8.7.380): A "rhombus" is a simple (non-self-intersecting) quadrilateral all of whose four sides have the same length. Another name is "equilateral quadrilateral", since equilateral means that all of its sides are equal in length. The rhombus is often named a "diamond", after the diamonds suit in playing cards which resembles the projection of an octahedral diamond, though the former sometimes refers specifically to a rhombus with a $\pi/3$ angle and the latter sometimes refers specifically to a rhombus with a $\pi/4$ angle.

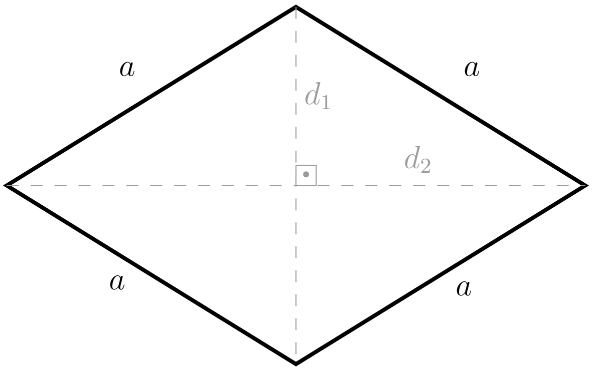

Figure 8.247: **Example of a rhombus**

Calculating the perimeter and the surface of the rhombus immediately follow from those of the trapezium.

8.7.1.12 Circle

There are several possible definitions of the circle. Let's look at least two.

Definitions (#8.7.381):

- D1. A "circle" is a special case of a polygon with an infinite number of sides.
- D2. A "circle" is a flat curve all of whose points are equidistant from a fixed point named "center".

Remark

A circle may also be defined as a special ellipse in which the two foci are coincident and the eccentricity is 0.

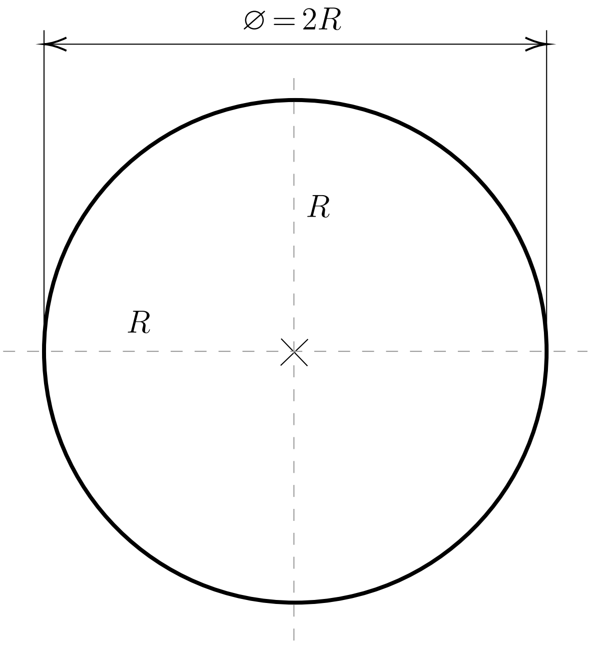

Figure 8.248: **Example of a circle**

We will prove in the section of Theoretical Computing at page 6298 that the perimeter of a circle of radius R and therefore of diameter $\varnothing=2R$ is given by:

$$\boxed{P=2\pi R=(2R)\pi=\varnothing\pi} \quad (8.7.71)$$

The relation for the surface (of the corresponding "disc") can be obtained in two common ways:

1. By the search of the primitive of perimeter P which gives us:

$$S=\int P\mathrm{d}R=2\pi\int R\mathrm{d}R=\pi R^2 \quad (8.7.72)$$

2. The second method is more aesthetic and uses the parametric equation of the circle, trivially given by the orthogonal projections of the Cartesian coordinates (see section Vector Calculus page 1863):

$$\begin{aligned} x &= R\cos(\theta) \\ y &= R\sin(\theta) \end{aligned} \tag{8.7.73}$$

We know that the area described by a function $f(x)$ is given by (see section Differential and Integral Calculus page 1497):

$$\boxed{S=\int\limits_a^b f(x)\mathrm{d}x=\int\limits_a^b y\mathrm{d}x} \tag{8.7.74}$$

We just have to substitute in this integral the parametrized variables:

$$y=R\sin(\theta) \qquad \mathrm{d}x=\mathrm{d}(R\cos(\theta))=R\mathrm{d}\cos(\theta)=-R\sin(\theta)\mathrm{d}\theta \tag{8.7.75}$$

Therefore:

$$S=\int\limits_a^b y\mathrm{d}x=\int\limits_a^b (R\sin(\theta))(-R\sin(\theta)\mathrm{d}\theta)=-R^2\int\limits_a^b \sin^2(\theta)\mathrm{d}\theta \tag{8.7.76}$$

The limits of integration are obviously $\theta=[0,2\pi]$ then we have:

$$\begin{aligned} S&=-R^2\int\limits_0^{2\pi}\sin^2(\theta)\mathrm{d}\theta=-2R^2\int\limits_0^{\pi}\sin^2(\theta)\mathrm{d}\theta=-2R^2\int\limits_0^{\pi}\frac{1-\cos(2\theta)}{2}\mathrm{d}\theta \\ &=2R^2\left(\frac{\sin(2\theta)}{4}-\frac{\theta}{2}\right)\Bigg|_0^{-\pi}=R^2\theta\Big|_0^{-\pi}-R^2\frac{\sin(2\theta)}{2}\Bigg|_0^{-\pi}=R^2\pi \end{aligned} \tag{8.7.77}$$

We therefore also by this method:

$$S=\pi R^2=\pi\left(\frac{\varnothing}{2}\right)^2=\pi\frac{\varnothing^2}{4} \tag{8.7.78}$$

The length l of an opening angle range α of a circle of radius R is obviously given by:

$$l=\frac{2\pi R}{2\pi}\alpha=R\alpha \tag{8.7.79}$$

and the surface S_t of an opening angle α of a circle of radius R identically by:

$$S_t=\frac{\pi R^2}{2\pi}\alpha=\frac{R^2}{2}\alpha \tag{8.7.80}$$

Let us now determine the surface S_d of cutted a part of disc that is to say:

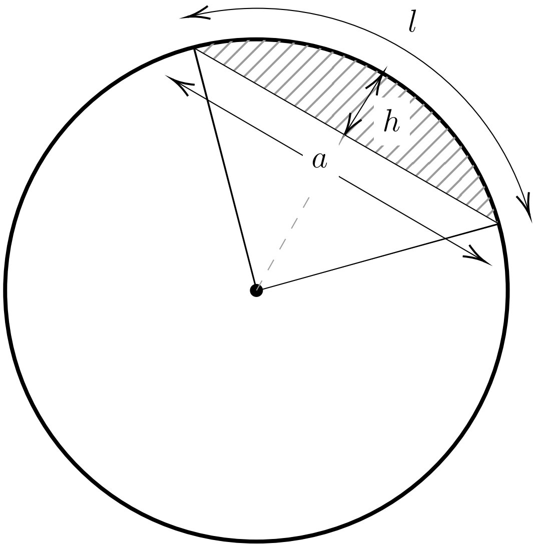

Figure 8.249: **Surface S_d of a disc cutted part**

We have:

$$S_d = \frac{R^2}{2}\alpha - \frac{a(R-h)}{2} = \frac{R^2}{2}\frac{l}{R} - \frac{a(R-h)}{2} = \frac{Rl - a(R-h)}{2} \tag{8.7.81}$$

Remark

A circle may also be defined as a special ellipse in which the two foci are coincident and the eccentricity is 0.

8.7.1.13 Ellipse

Definition (#8.7.382): An "ellipse" is a closed curve where every point P is such that the sum of its distances from two fixed points named "foci $F1, F2$" is constant (as we see it in details in the section of Analytical Geometry the ellipse can also be seen as an affine transformation of the circle).

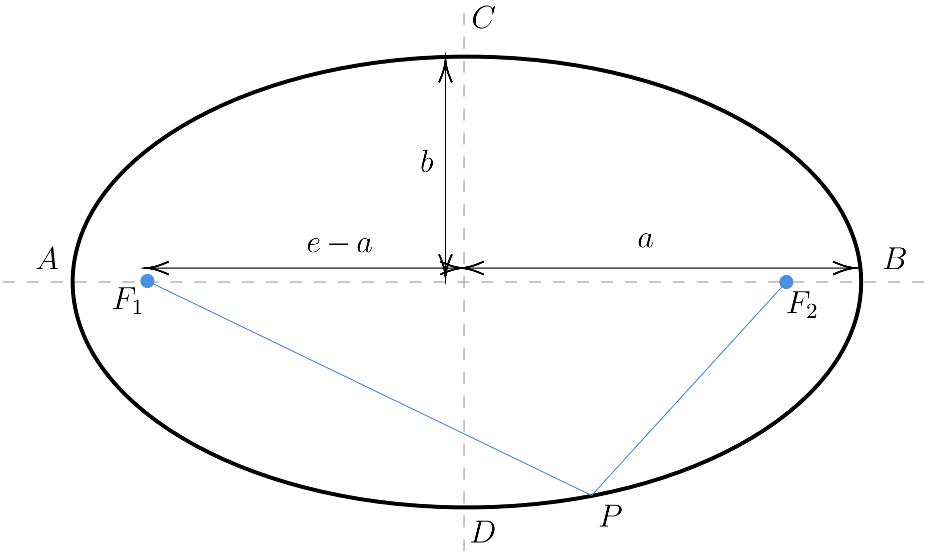

Figure 8.250: **Example of an ellipse with its visible foci and eccentricity e**

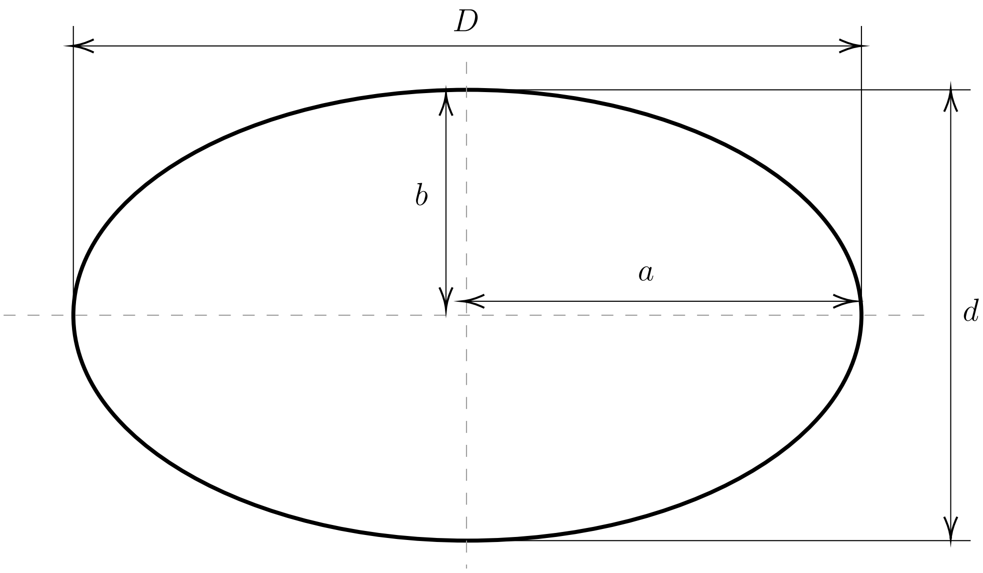
Remark

When am "ellipse" is a closed curve where every point P is such that the sum of its distances from two fixed points named "foci $F1, F2$" is constant an "oval" is a closed curve in a plane which resembles the outline of an egg (i.e. an oval is a curve resembling a squashed circle but, unlike the ellipse, without a precise mathematical definition).

The shape of an ellipse (how 'elongated' it is) is represented by its "eccentricity e", which for an ellipse can be any number from 0 (the limiting case of a circle) to arbitrarily close to but less than 1.

For the mathematical developments that will follow we will rather use the notation of the following figure:



Remark

The reader must therefore not forget that most important mathematical developments about the ellipse are in the section of Analytical Geometry (see page 2764).

Let us introduce to start a small text relative to the calculation of the perimeter of the ellipse!

Given the parametric equation in Cartesian coordinates of an ellipse (see section Vector Calculus page 1863):

$$\begin{aligned} x &= a\cos(\theta) \\ y &= b\sin(\theta) \end{aligned} \tag{8.7.82}$$

The distance between the center of the ellipse and its perimeter is given by the Pythagorean Theorem:

$$R(\theta)=\sqrt{a^2\cos^2(\theta)+b^2\sin^2(\theta)} \tag{8.7.83}$$

An arc element is then given by:

$$R(\theta)\mathrm{d}\theta=\sqrt{a^2\cos^2(\theta)+b^2\sin^2(\theta)}\mathrm{d}\theta \tag{8.7.84}$$

The perimeter of the ellipse is the given by the integral:

$$P=\int\limits_0^{2\pi} R(\theta)\mathrm{d}\theta=\int\limits_0^{2\pi}\sqrt{a^2\cos^2(\theta)+b^2\sin^2(\theta)}\mathrm{d}\theta=4\int\limits_0^{\pi/2}\sqrt{a^2\cos^2(\theta)+b^2\sin^2(\theta)}\mathrm{d}\theta \tag{8.7.85}$$

and then it starts to get tougher... This type integral can not easily be calculated using the usual primitives, integration by parts or change of variables. This is what we name a "second-order elliptic integral J" for $0<b<a$ (see section Differential and Integral Calculus page 1599):

$$\boxed{J(a,b)=\int\limits_0^{\pi/2}\sqrt{a^2\cos^2(\theta)+b^2\sin^2(\theta)}\mathrm{d}\theta} \tag{8.7.86}$$

Long developments which we present in a few years in the section of Differential and Integral Calculus give for calculating the perimeter after a limited series:

$$\boxed{P\cong\sqrt{2(a^2+b^2)}=2\pi a\sqrt{1-e^2}} \tag{8.7.87}$$

The surface of the ellipse can be obtained in a very similar manner to that of the circle and the calculations are surprisingly much simpler than those of its perimeter. Remember that the parametric equation the ellipse is:

$$\begin{aligned} x &= a\cos(\theta) \\ y &= b\sin(\theta) \end{aligned} \tag{8.7.88}$$

We know that the area described by a function $f(x)$ is given by:

$$S=\int\limits_a^b f(x)\mathrm{d}x=\int\limits_a^b y\mathrm{d}x \tag{8.7.89}$$

We just have to substitute in this integral the parametrized variables:

$$y=b\sin(\theta) \qquad \mathrm{d}x=\mathrm{d}(a\cos(\theta))=a\mathrm{d}\cos(\theta)=-a\sin(\theta)\mathrm{d}\theta \tag{8.7.90}$$

Therefore:

$$S=\int\limits_a^b y\mathrm{d}x=\int\limits_a^b (b\sin(\theta))(-a\sin(\theta)\mathrm{d}\theta)=-ab\int\limits_a^b \sin^2(\theta)\mathrm{d}\theta \tag{8.7.91}$$

The limits of integration being obviously $\theta=[0,-2\pi]$ we have:

$$\begin{aligned}S&=-ab\int\limits_0^{-2\pi}\sin^2(\theta)\mathrm{d}\theta=-2ab\int\limits_0^{-\pi}\frac{1-2\cos(2\theta)}{2}\mathrm{d}\theta=-2ab\left(\frac{1}{2}\theta-\frac{1}{4}\sin(2\theta)\right)\Bigg|_0^{-\pi}\\&=-2ab\left[\left(\frac{1}{2}(-\pi)-\frac{1}{4}\sin(2(-\pi))\right)-\left(\frac{1}{2}\cdot 0-\frac{1}{4}\sin(2\cdot 0)\right)\right]\\&=-2ab\frac{1}{2}(-\pi)=ab\pi\end{aligned} \tag{8.7.92}$$

Remark

Be careful with this kind of calculations with the order of integration bounds. Indeed, if we had taken the bounds from $[0,\pi]$ (instead of $[0,-\pi]$) one must imagine that the integrated function browse the perimeter in the negative direction of the x-axis. So the integral would be necessarily be negative.

We therefore also have for this method:

$$\boxed{S=\pi ab=\frac{\pi}{4}D\cdot d} \tag{8.7.93}$$

Remarks

R1. We assume as obvious (and therefore without proof) that the ellipse's center of gravity coincides with the center of it.

R2. We send the reader to the study of conical (see section Analytical Geometry page 2764) for the calculation of the area of an ellipse from its "ellipse parameter" and its "eccentricity" (everything is prove there).

8.7.1.13.1 Ellipse section surface

Now let us focus on a common question on Internet Forums: What is the area of a section of an ellipse. To answer that question we start again from:

$$\begin{aligned}x&=a\cos(\theta)\\y&=b\sin(\theta)\end{aligned} \tag{8.7.94}$$

but that we will write a in slightly different way:

$$\begin{aligned} x &= r(\theta)\cos(\theta) \\ y &= r(\theta)\sin(\theta) \end{aligned} \tag{8.7.95}$$

An element of surface in polar coordinates is given by:

$$\mathrm{d}S = r(\theta)\mathrm{d}r\mathrm{d}\theta \tag{8.7.96}$$

Therefore the area of a section has for expression:

$$S = \int\limits_{\theta_1}^{\theta_2}\int\limits_{0}^{r(\theta)} r\mathrm{d}r\mathrm{d}\theta \tag{8.7.97}$$

Thus:

$$S = \frac{1}{2}\int\limits_{\theta_1}^{\theta_2} r^2(\theta)\mathrm{d}\theta \tag{8.7.98}$$

But using what we have seen in the section of Analytical Geometry we can write that latter:

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1 = r(\theta)\left(\frac{\cos^2(\theta)}{a^2} + \frac{\sin^2(\theta)}{b^2}\right) \tag{8.7.99}$$

Therefore:

$$r^2(\theta) = \frac{1}{\dfrac{\cos^2(\theta)}{a^2} + \dfrac{\sin^2(\theta)}{b^2}} \tag{8.7.100}$$

Thus:

$$S = \frac{1}{2}\int\limits_{\theta_1}^{\theta_2} r^2(\theta)\mathrm{d}\theta = \frac{1}{2}\int\limits_{\theta_1}^{\theta_2} \frac{\mathrm{d}\theta}{\dfrac{\cos^2(\theta)}{a^2} + \dfrac{\sin^2(\theta)}{b^2}} \tag{8.7.101}$$

To continue let us make a simple change of variables:

$$\int\limits_{\theta_1}^{\theta_2} \frac{\mathrm{d}\theta}{a'^2\cos^2(\theta) + b'^2\sin^2(\theta)} \tag{8.7.102}$$

Pulling out $a'^2\cos^2(\theta)$ we get:

$$\int \frac{\mathrm{d}\theta}{a'^2\cos^2(\theta)\left(1 + \dfrac{b'^2}{a'^2}\tan^2(\theta)\right)} \tag{8.7.103}$$

Now we make a serious change of variable:

$$u = \frac{b'}{a'}\tan(\theta) \tag{8.7.104}$$

Thus according to the usual derivatives (see section Differential and Integral Calculus page 1475):

$$\mathrm{d}u=\frac{b'}{a'}\frac{1}{\cos^2(\theta)}\mathrm{d}\theta \tag{8.7.105}$$

Then the integral becomes:

$$\frac{1}{a'^2}\int\frac{\mathrm{d}\theta}{\cos^2(\theta)\left(1+\dfrac{b^2}{a^2}\tan^2(\theta)\right)}=\frac{1}{a'^2}\int\frac{\dfrac{a'}{b'}\mathrm{d}u}{1+u^2}=\frac{1}{a'b'}\int\frac{\mathrm{d}u}{1+u^2} \tag{8.7.106}$$

We know according to usual integrals that (see section Differential and Integral Calculus page 1534):

$$\frac{1}{a'b'}\int\frac{\mathrm{d}u}{1+u^2}=\frac{1}{a'b'}\arctan(u)=\frac{1}{a'b'}\arctan\left(\frac{b'}{a'}\tan(\theta)\right) \tag{8.7.107}$$

So finally:

$$\boxed{S=\frac{ab}{2}\arctan\left(\frac{a}{b}\tan(\theta)\right)\Bigg|_{\theta_1}^{\theta_2}} \tag{8.7.108}$$

Figure 8.251: Surface elements $\mathrm{d}S$ in 2D

8.7.2 Usual Volumes

There are several definitions of the concept of volume (surface that limits a body). A definition due to Euclid and another due to the field of Topology (see the section of the same name).

Definitions (#8.7.383):

D1. A "volume" is an entity that has a length, a width and a height.

D2. A "volume" is a 3-manifold topology.

The surfaces that surround a body may be planar or curved:

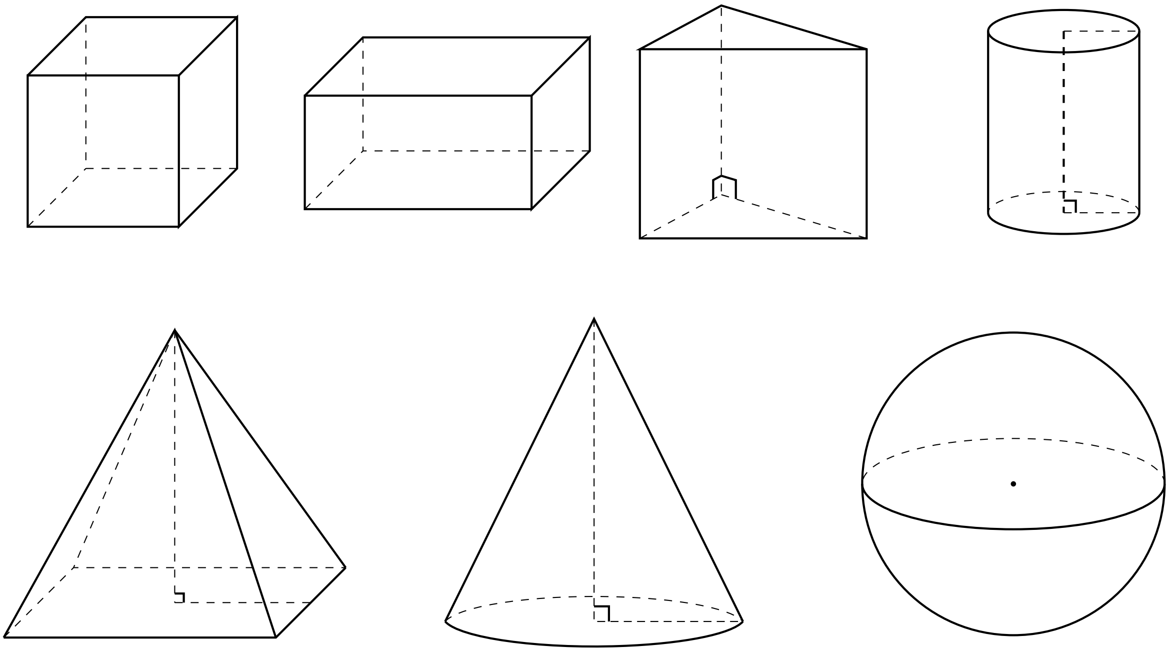

Figure 8.252: **Simple volumes bounded by a surface**

On the left, the body is limited only by planar surfaces, in the middle by one and only one single curved surface, and on the right by a curved surface and two planar surfaces.

Remark

We will focus initially only to the properties (area, volume, center of gravity, moment of inertia ...) of volumes plunged into Euclidean geometries.

8.7.2.1 Polyhedron

The study of polyhedra (especially Platonic polyhedra) is very important in physics (e.g. crystallography) and also in mathematics because it gives a nice application of finite groups (see section Set Algebra page 1420). It is therefore appropriate to carefully read what will follow.

Furthermore, the study of polyhedra is also a very educational and aesthetic way to see the implementation of several geometric, trigonometric and vector algebra theorems.

It should be noted before all that the various polyhedra will deliberately not presented as equal in their study. Thus, we will focus only on given properties for some and not for others.

Definitions (#8.7.384):

D1. A "polyhedron" is a solid whose border is formed of plans or plan portions. The plan the portions, which include between them the polyhedron, are the faces; each face being limited by intersections (edges) with neighbouring faces, is a polygon. The sides of this polygon are the edges of the polyhedron. We name "vertices" of a polyhedron any vertex of any of its faces.

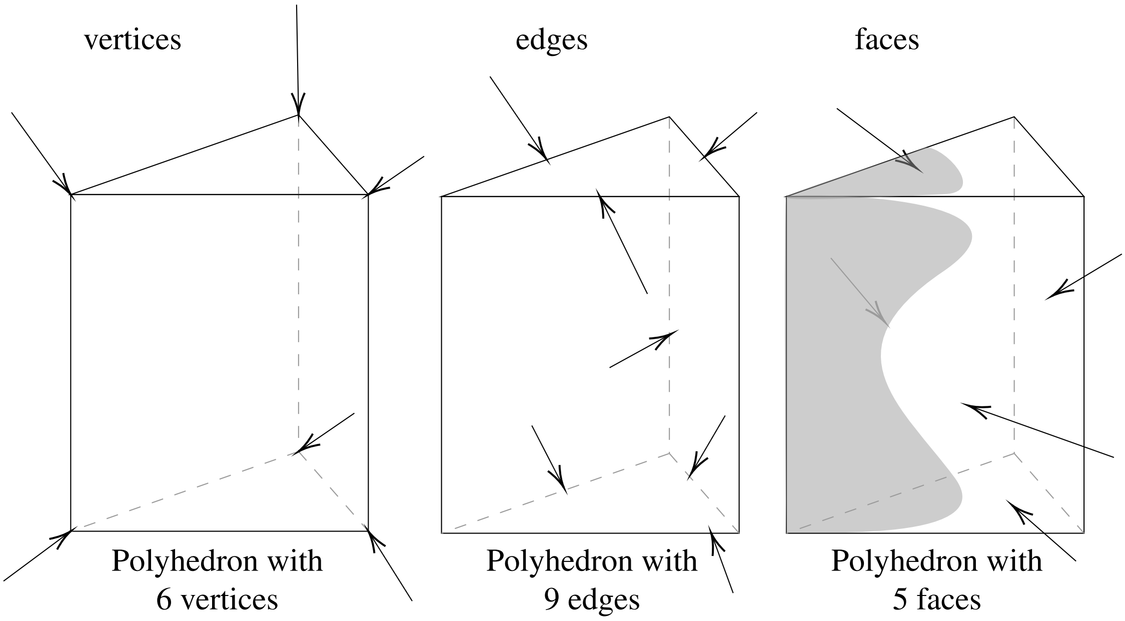

Figure 8.253: **Polyhedron vocabulary**

D2. A "regular polygon" is a polygon which sides and all angles are equal (this definition will be useful for regular polyhedra further below).

8.7.2.1.1 Parallelepiped

Definition (#8.7.385): In geometry, a "parallelepiped" is a three-dimensional figure formed by six parallelograms (the term rhomboid is also sometimes used with this meaning). By analogy, it relates to a parallelogram just as a cube relates to a square or as a cuboid to a rectangle.

Three equivalent definitions of parallelepiped are:

- A polyhedron with six faces (hexahedron), each of which is a parallelogram.
- A hexahedron with three pairs of parallel faces
- A prism of which the base is a parallelogram.

The rectangular cuboid (six rectangular faces), cube (six square faces), and the rhombohedron (six rhombus faces) are all specific cases of parallelepiped (see further below for details about these polyhedrons).

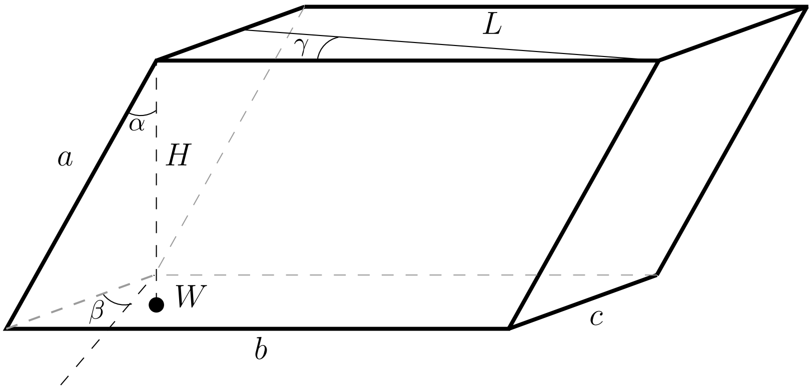

Figure 8.254: **General parallelepiped**

Definitions (#8.7.386):

D1. The parallelepiped is a "cube" if and only if:

$$a=b=c \qquad \text{and} \qquad \alpha=\beta=\gamma=0 \tag{8.7.109}$$

D2. The parallelepiped is a "cuboid" (rectangular parallelepiped) if and only if:

$$\alpha=\beta=\gamma=0 \tag{8.7.110}$$

D3. The parallelepiped is a "rhombohedron" if and only if:

$$a=b=c \tag{8.7.111}$$

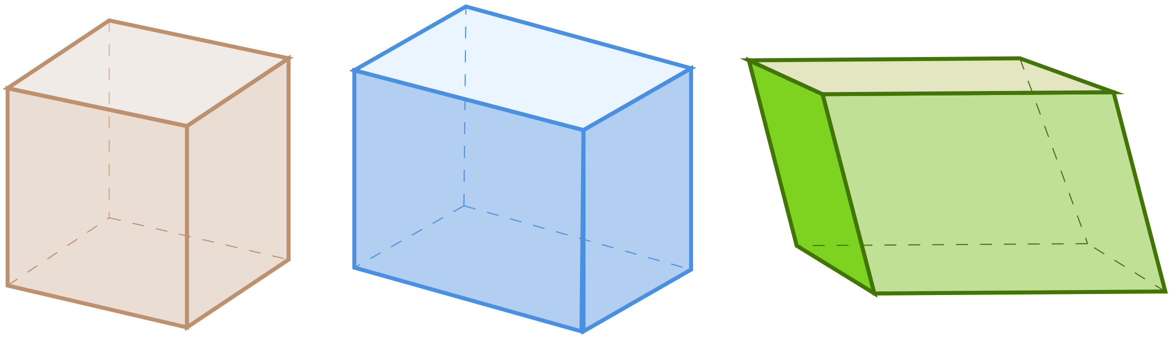

Figure 8.255: Cube, Cuboid and Rhombohedron

The volume of the parallelepiped is simply obtained by using trigonometric properties. We can consider mainly two situations:

- We know H, b, c, α and the volume is obviously given by:

$$\boxed{V = Hbc = \frac{\cos(\alpha)}{a}bc} \tag{8.7.112}$$

Obviously we get therefore for a cuboid where $a = b = c$:

$$\boxed{V = a^3} \tag{8.7.113}$$

- If we know only α, β, γ and H, W, L:

$$V = \frac{J}{\cos(\alpha)}\frac{L}{\cos(\gamma)}\frac{W}{\cos(\beta)} = abc \tag{8.7.114}$$

About its surface, it is simply the sum of the surfaces of each of its parallelogram without anything special (we have already prove earlier how to calculate the surface of a parallelogram) and therefore we need to know all deformation angles of each parallelogram.

8.7.2.1.1.1 Moment of Inertia of a rectangular plate

Now let us calculate the moment of inertia of a plate (rectangular parallelepiped) of cross-sectional area S which axis of rotation is the y-axis:

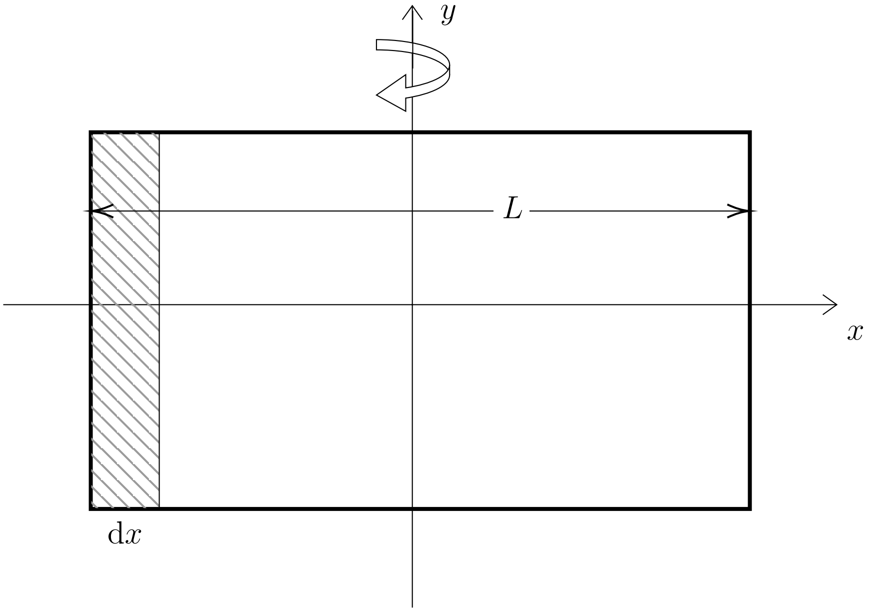

Figure 8.256: Search for the moment of inertia of a plate along the section

A volume element of the rectangle (in gray) is given by:

$$\mathrm{d}V = S\mathrm{d}x \Longrightarrow \mathrm{d}m = \rho S\mathrm{d}x \qquad (8.7.115)$$

and (see section Classical Mechanics page 3297):

$$J_y = \int x^2\mathrm{d}m = \int_{-L/2}^{+L/2} x^2\rho\mathrm{d}m = \rho S\left\{\frac{\left(\frac{L}{2}\right)^3}{3} - \frac{\left(\frac{L}{2}\right)^3}{3}\right\} = \rho\frac{SL^3}{12} = \rho SL\frac{L^2}{12} = M\frac{L^2}{12} \qquad (8.7.116)$$

Using Steiner's theorem (see section Classical Mechanics page 3310) we can easily get the moment of inertia of this plate when the rotation axis is collinear to the borders of the latter:

$$J_{y'} = M\frac{L^2}{36}\left(\frac{L}{e}\right)^2 M = M\frac{L^2}{12} + \frac{L^2}{4}M = \frac{4L^2M}{12} = \frac{L^2M}{3} \qquad (8.7.117)$$

and let us now focus on the moment of inertia of the plate relative to the z-axis (perpendicular to x and y therefore) and let us put axes so we have:

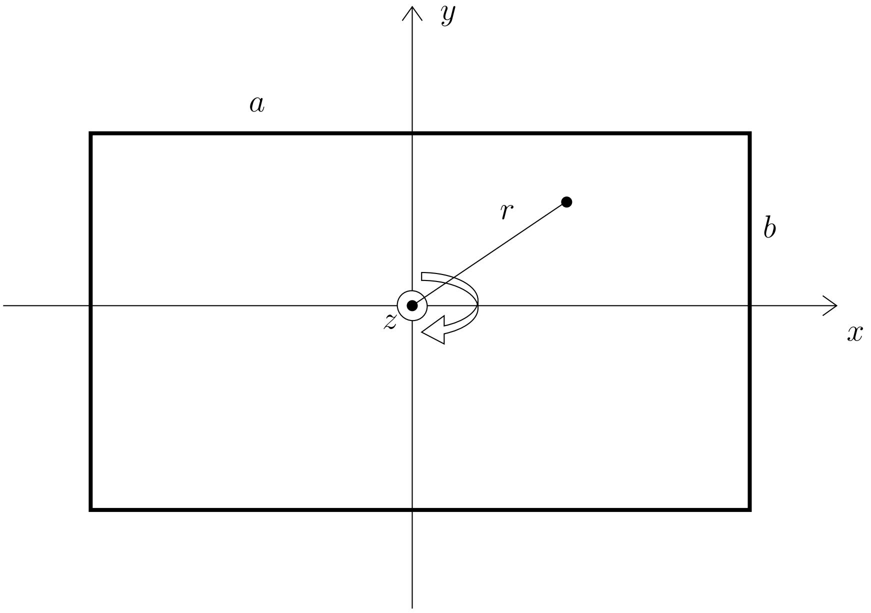

Figure 8.257: **Search for the moment of inertia of a plate along perpendicular axis**

We have:

$$J_z = \int r^2 \mathrm{d}m = \int (x^2+y^2)\mathrm{d}m = \int x^2 \mathrm{d}m + \int y^2 \mathrm{d}m = J_x + J_y \tag{8.7.118}$$

where r is in the x and y plane.

With:

$$\begin{aligned} J_x &= \int y^2 \mathrm{d}m = \int_{-b/2}^{+b/2} y^2 \rho e a \mathrm{d}y = \rho e a \int_{-b/2}^{+b/2} y^2 \mathrm{d}y = \frac{\rho e a}{3}\left\{\left(\frac{b}{2}\right)^3 - \left(-\frac{b}{2}\right)^3\right\} = \frac{M}{12}b^2 \\ J_y &= \int x^2 \mathrm{d}m = \int_{-a/2}^{+a/2} x^2 \rho e a \mathrm{d}x = \rho e a \int_{-a/2}^{+a/2} x^2 \mathrm{d}x = \frac{\rho e a}{3}\left\{\left(\frac{a}{2}\right)^3 - \left(-\frac{a}{2}\right)^3\right\} = \frac{M}{12}a^2 \end{aligned} \tag{8.7.119}$$

Therefore:

$$\boxed{J_{\square,z} = J_x + J_y = \frac{M}{12}\left(a^2+b^2\right)} \tag{8.7.120}$$

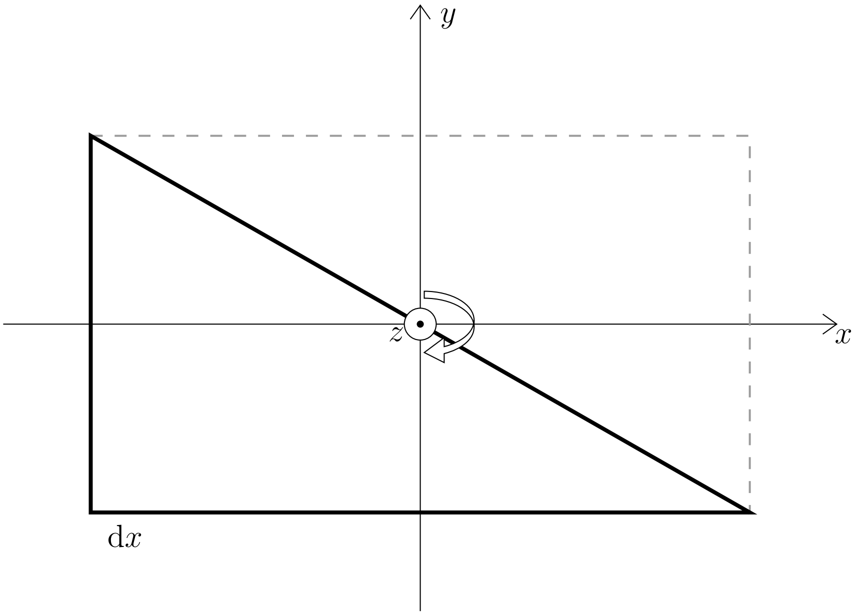
If the plate is a square of side L:

$$J_z = \frac{M}{12}\left(a^2+b^2\right) = \frac{M}{12}\left(L^2+L^2\right) = \frac{ML^2}{6} \tag{8.7.121}$$

8.7.2.1.1.2 Moment of Inertia of a triangular plate

We will now prove that it possible to calculate the moment of inertia of an equilateral triangle plate and rectangle triangle plate for an axis passing still through the centroid from the latter.

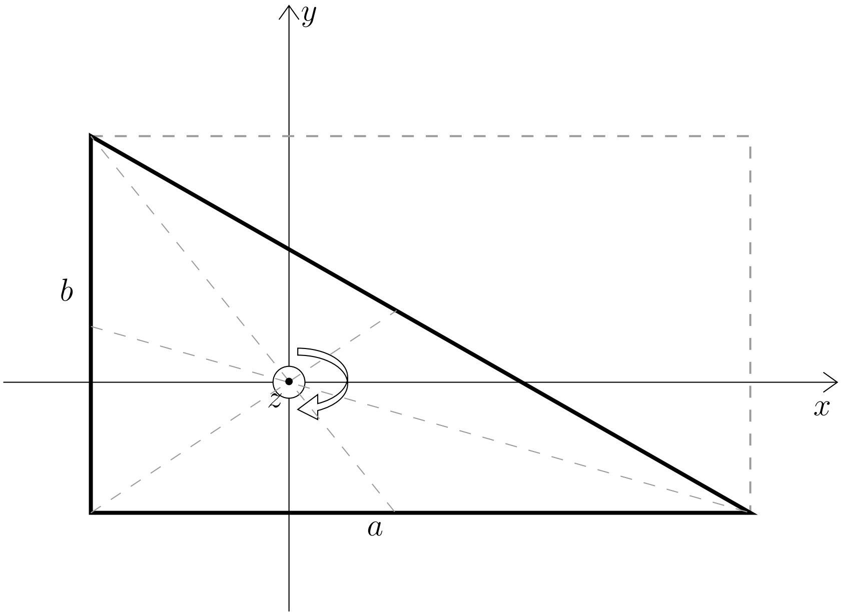
The method we propose here is direct and almost... brutal.... Indeed, we consider the moment of inertia always from the same axis, but for half the rectangle:



First we have obviously now:

$$J_z = \frac{1}{2}\frac{M}{12}(a^2+b^2) = \frac{M}{24}(a^2+b^2) \tag{8.7.122}$$

But we want the moment inertia of this equilateral triangle trough its centroid! That is to say:



Therefore as the center of gravity is placed now on the third of the median starting at the square's center (see proof previously) of gravity and that we make use of Steiner's theorem (see section Classical Mechanics page 3310) we get:

$$J_z=\frac{M}{24}(a^2+b^2)-\left(\frac{1}{3}\left(\sqrt{(0.5a)^2+(0.5b)^2}\right)\right)^2M=\frac{M}{24}(a^2+b^2)-\left(\frac{1}{6}\left(\sqrt{a^2+b^2}\right)\right)^2M \tag{8.7.123}$$

If $a=b=L$ we have the famous special case:

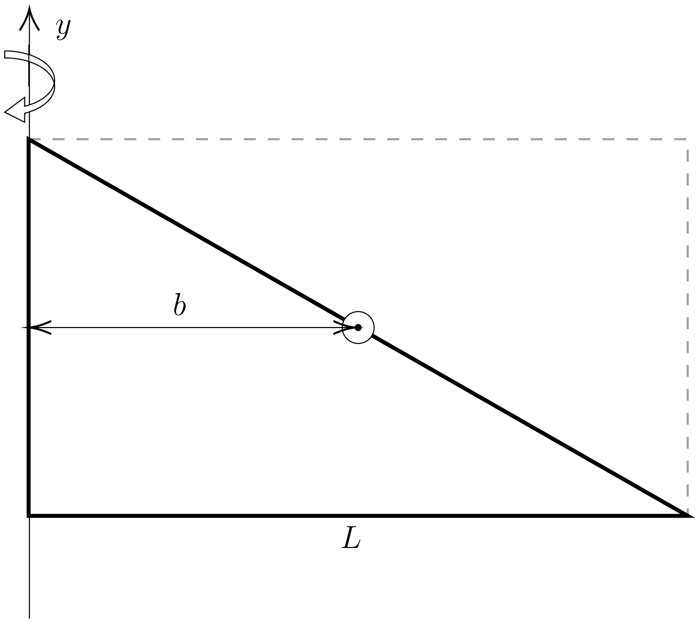
$$\begin{aligned}J_z&=\frac{M}{24}(L^2+L^2)-\left(\frac{1}{6}\left(\sqrt{L^2+L^2}\right)\right)^2M=\frac{L^2M}{12}-\left(\frac{1}{6}\left(\sqrt{2}L\right)\right)^2M\\&=\frac{L^2M}{12}-\frac{2L^2M}{36}=\frac{3L^2M}{36}-\frac{2L^2M}{36}=\frac{ML^2}{36}\end{aligned} \tag{8.7.124}$$

If we have $a=b=L$ then the rectangle has a height $h=L$ this is why we can found most of time the previous relation in textbooks written as:

$$\boxed{J_{\triangle,z}=\frac{Mh^2}{36}} \tag{8.7.125}$$

which is the moment of inertia of an equilateral triangle plate for the special case of an axis passing through the center of mass (gravity).

For sure as for other geometries we can choose any other axis and the possibilities are limitless... But to end we will calculate the moment of inertia of a rectangular triangle plate (right angle triangle) of dimensions a,b whose rotation axis is along the y-axis but translated of $b/2$ (that is to say: the rotation axis is collinear to the basis of length a of the rectangle triangle plate):



Remember for this that we have first proved just above that for a rectangular plate in rotation along the a border was:

$$J_{y'}=\frac{L^2M}{3} \tag{8.7.126}$$

Applying once again Steiner's theorem AND for half a plate (therefore for a rectangle triangle plate) we get immediately:

$$J_y = \frac{L^2M}{3} - \left(\frac{L}{2}\right)^2 M = \frac{L^2M}{3} - \frac{L^2M}{4} = \frac{4L^2M - 3L^2M}{12} = \frac{L^2M}{12} \tag{8.7.127}$$

And if we put as usual $L := h$ then we get the another famous result:

$$\boxed{J_y = \frac{h^2M}{12}} \tag{8.7.128}$$

As we can see the inertia momentum in this configuration is the same as that one with a rectangular plate having the rotation axis trough the centroid following the y-axis.

8.7.2.1.2 Pyramid

Definition (#8.7.387): The "pyramid" is a polyhedron whose base is a polygon and for side faces triangles connected on a single point made the "apex". The pyramid is not in the general case a regular polyhedron! A "right pyramid" has its apex directly above the centroid of its base. Non-right pyramids are named "oblique pyramids". A "regular pyramid" has a regular polygon base and is usually implied to be a right pyramid. When unspecified, a pyramid is usually assumed to be a "regular square pyramid".

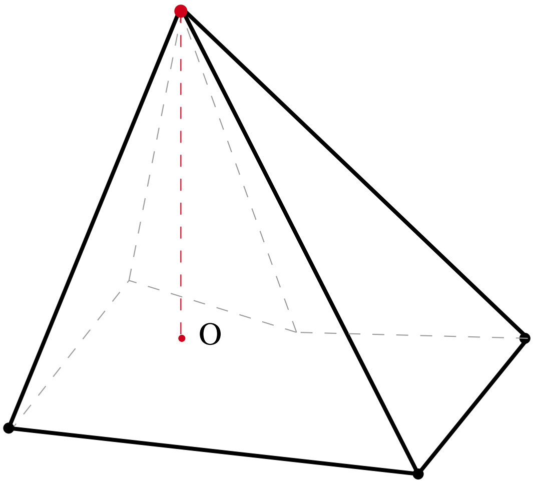


Figure 8.258: **Example of pyramid (irregular basis) but non-oblique**

Consider a surface $S(t)$ of the section of the pyramid with the plane of $z = t$ (that is to say for $t = 0$ we have the surface of the basis of the pyramid), then the volume V we are looking for will be equal to:

$$V = \int_0^h S(t)\mathrm{d}t \tag{8.7.129}$$

We speak of plane equation when there is no defined basis for now. In fact, in the integral, t varies between 0 and h. This implies that we take a basis centered on H (the projection of the apex of the pyramid on the basis), of axis therefore oriented towards $\overline{HO}$. The other two axes are chosen arbitrary in the plane of the basis of the pyramid.

We must now clarify what is $S(t)$ depending on t:

Let $S(0)=S$ be the area of the base of the pyramid. The section of the pyramid by the plane of equation $z=t$ is deduced by the scaling of center O and ratio t/h. So the integral is written:

$$V=\int_0^h S(t)\mathrm{d}t=\int_0^h S\frac{t^2}{h^2}\mathrm{d}t \tag{8.7.130}$$

where the fact that having taken the square of t/h is due to the fact that each inner term of S is the product of two terms (by the definition of a surface that is the multiplication of the length) each of homothetic ratio t/h.

Thus we have:

$$\boxed{V=\frac{S}{h^2}\int_0^h t^2\mathrm{d}t=\frac{Sh}{3}} \tag{8.7.131}$$

8.7.2.1.2.1 Moment of Inertia of a regular square pyramid

We have along the axis of symmetry of the regular square pyramid of height h and side a:

$$J_z=\int r^2\mathrm{d}m=\int(\sqrt{x^2+y^2})^2\mathrm{d}m=\int(x^2+y^2)\mathrm{d}m \tag{8.7.132}$$

As:

$$V=\frac{Sh}{3} \tag{8.7.133}$$

We have for the mass of the pyramid:

$$M=\rho\frac{Sh}{3}=\rho\frac{a^2h}{3} \tag{8.7.134}$$

So:

$$\mathrm{d}m=\rho\frac{\mathrm{d}x\mathrm{d}y\mathrm{d}z}{3} \tag{8.7.135}$$

Therefore:

$$\begin{aligned}
J_z=J_z&=\rho\int\limits_0^h \mathrm{d}z\int\limits_{-\frac{az}{2h}}^{\frac{az}{2h}}\mathrm{d}y\int\limits_{-\frac{az}{2h}}^{\frac{az}{2h}}(x^2+y^2)\mathrm{d}x=\rho\int\limits_0^h \mathrm{d}z\int\limits_{-\frac{az}{2h}}^{\frac{az}{2h}}\mathrm{d}y\left(\frac{1}{3}x^3+y^2x\right)\Bigg|_{-\frac{az}{2h}}^{\frac{az}{2h}}\\
&=2\rho\int\limits_0^h \mathrm{d}z\int\limits_{-\frac{az}{2h}}^{\frac{az}{2h}}\mathrm{d}y\left(\frac{1}{3}\frac{a^3z^3}{8h^3}+\frac{az}{2h}y^2\right)=2\rho\int\limits_0^h \mathrm{d}z\left(\frac{1}{3}\frac{a^3z^3}{8h^3}y+\frac{1}{3}\frac{az}{2h}y^3\right)\Bigg|_{-\frac{az}{2h}}^{\frac{az}{2h}}\\
&=4\rho\int\limits_0^h \mathrm{d}z\left(\frac{1}{3}\frac{a^4z^4}{16h^4}+\frac{1}{3}\frac{a^4z^4}{16h^4}\right)=4\rho\int\limits_0^h\frac{2}{3}\frac{a^4z^4}{16h^4}\mathrm{d}z=\frac{a^4\rho}{6h^4}\int_0^h z^4\mathrm{d}z=\frac{a^4\rho}{6h^4}\frac{1}{5}h^5\\
&=\frac{a^4\rho}{6}\frac{1}{5}h=\frac{1}{10}\frac{1}{3}a^2h\rho a^2=\frac{1}{10}ma^2
\end{aligned}\tag{8.7.136}$$

8.7.2.1.3 Right Prism

Definition (#8.7.388): The "(right) prism" is a polyhedron whose bases are two equals polygons with parallel sides (they have the same surface!), The side faces are parallelograms. Therefore, the prism is not a regular polyhedron! The two parallel sides and shapes are named bases of the (right) prism.

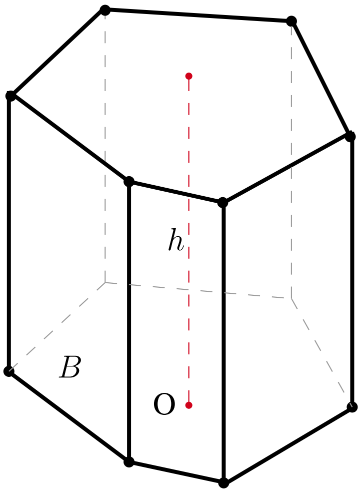

Figure 8.259: Example of right prism

To calculate the volume V of a right prism, we simply multiply the area of its base B by its height h:

$$V=Bh\tag{8.7.137}$$

As its base is a polygon, that is to say, it can be a triangle, a quadrilateral or a pentagon ... The reader must know how to calculate these areas to calculate the volume of the right prism.

A right prism with a triangular basis is named a "triangular prism", a right prism with a rectangular basis is named a... "cuboid", a right prism with a square base is named a... "cube" and a right prism with a circular basis is named a... "cylinder"...

8.7.2.1.4 Regular Polyhedron

Definitions (#8.7.389):

D1. A "regular polyhedron" is made of all identical and regular surfaces. A common equivalent definition is that a regular polyhedron is such that faces are congruent regular polygons which are assembled in the same way around each vertex.

D2. A "convex polyhedron" is such that each point of a line segment joining any two points belongs to the (inside of) polyhedron.

The regular polyhedra are at the number of nine, where five of them are convex and are known as the Platonic Solids. We sometimes named regular polyhedra only the Platonic solids and it is these that will interest us here.

Theorem 8.27. We will prove that there are only five convex regular polyhedra, which are therefore named the "five Platonic solids" (the other columns of the table below will be proved and explained a little further), a regular polyhedron is identified by its "Schläfli symbol" of the form (m, n), where m is the number of sides of each face and n the number of faces meeting at each vertex.

For the proof we will denote by A the number of edges, S the number of nodes (vertices) and F the number of faces.

Name	**Schläfli** (m,n)	**Image**	S	A	F	$F-A+S$
Tetrahedron	$(3,3)$		4	6	4	2
Cube	$(4,3)$		8	12	6	2
Octahedron	$(3,4)$		6	12	8	2
Dodecahedron	$(5,3)$		20	30	12	2
Icosahedron	$(3,5)$		12	30	20	2

Table 8.7: **Five regular polyhedra (Platonic Solids)**

Remark

A "Platonic hydrocarbon" is a hydrocarbon (molecule) whose structure matches one of the five Platonic solids, with carbon atoms replacing its vertices, carbon–carbon bonds replacing its edges, and hydrogen atoms as needed. As far as we know, not all Platonic solids have molecular hydrocarbon counterparts.

Proof 8.27.1. Let m be the number of sides of each surface of a regular polyhedron, n the number of edges that meet at each vertex. We have therefore that each angle of any face is given by:

$$2\beta=\frac{\pi}{2}\left(2-\frac{4}{m}\right) \tag{8.7.138}$$

Caution!!! It is the angle 2β that defines the angle of a face and not just β!

Which is deduced from the following figure:

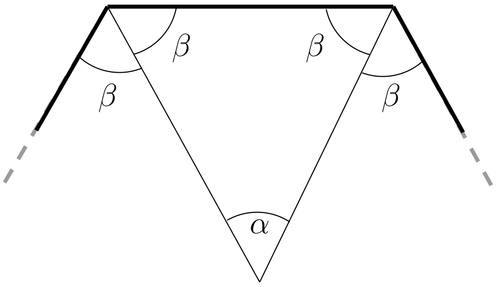

Figure 8.260: Angles between the edges of a polyhedron

where we have:

$$\alpha=\frac{2\pi}{m} \tag{8.7.139}$$

and:

$$2\beta=\pi-\alpha=\pi-\frac{2\pi}{m}=\frac{\pi}{2}\left(2-\frac{4}{m}\right) \tag{8.7.140}$$

But the sum of n angles grouped around a vertex is smaller than the n angles which intersect a plane into equal parts (we assume that intuitive by cutting)! Each of them is less than:

$$\frac{2\pi}{n} \tag{8.7.141}$$

therefore:

$$\frac{\pi}{2}\left(2-\frac{4}{m}\right)<\frac{2\pi}{n} \tag{8.7.142}$$

hence:

$$\frac{1}{m}+\frac{1}{n}>\frac{1}{2} \tag{8.7.143}$$

The numbers m and n are both at least equal to 3 (the smallest polygon being a triangle). It follows that the only possible cases are:

$$(m,n)=\{(3,3),(3,4),(4,3),(3,5),(5,3)\} \tag{8.7.144}$$

■ Q.E.D.

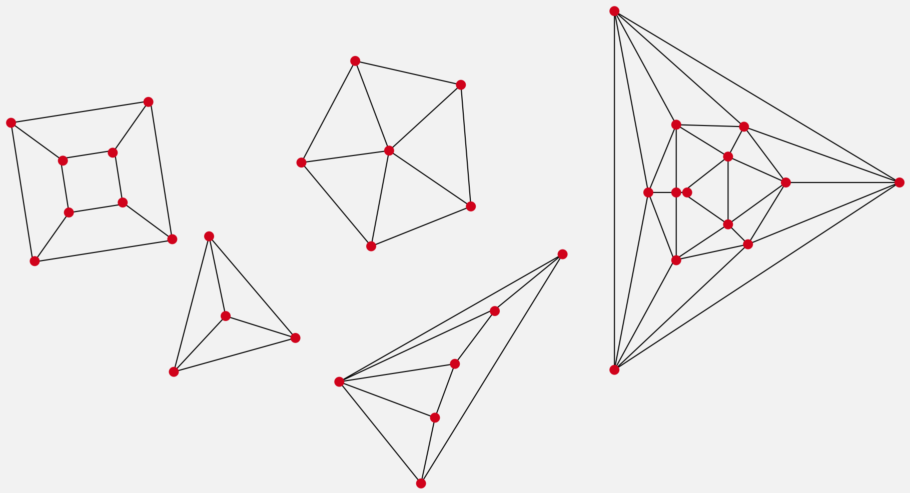
Let us denote now by F the number of faces, A the number of edges and S the number of vertices (nodes). Let recall that we have proved in the section of Graph Theory the "Euler's formula" at page 3002 (also named "Descartes-Euler's theorem" or "polyhedral formula") such that:

$$\boxed{F-A+S=2} \tag{8.7.145}$$

and it is of course also valid for the flattening of a polyhedron in the plane (and therefore of a polyhedron in the space).

Remark

The representation as a flattening graph of a polyhedron is named a "Schlegel diagram" and is used in some fields of organic chemistry.



In the case of regular polyhedra, each side (face) has m edges so that $m \cdot F$ is the whole number of edges of all sides and as each edge as encounter exactly two faces, we have the equality (take an example to be convinced if necessary!):

$$mF = 2A \tag{8.7.146}$$

and as n is the number of edges that meet at each vertex, and that each edge connects two vertices, we also have:

$$mF = nS \tag{8.7.147}$$

Therefore:

$$mF = nS = 2A \tag{8.7.148}$$

By injecting into Euler's formula, we have then:

$$\frac{2A}{m} - A + \frac{2A}{n} = 2 \Rightarrow \frac{1}{m} + \frac{1}{n} = \frac{1}{A} + \frac{1}{2} > 2 \tag{8.7.149}$$

and we fall back on the inequality of the previous theorem. Let us take again our calculation:

$$F - A + S = 2 = F - \frac{mF}{2} + \frac{mF}{n} = F\left(1 - \frac{m}{2} + \frac{m}{n}\right) \tag{8.7.150}$$

from which we get:

$$F = \frac{2}{1 - \dfrac{m}{2} + \dfrac{m}{n}} = \frac{2}{\dfrac{2n}{2n} - \dfrac{mn}{2n} + \dfrac{2m}{2n}} = \frac{4n}{2n - mn + 2m} \tag{8.7.151}$$

We can now undertake the classification of regular polyhedra:

1. The tetrahedron $(m,n) = (3,3)$:

$$F = \frac{4n}{2n - mn + 2m} = \frac{12}{6 - 9 + 6} = 4 \quad A = \frac{mF}{2} = \frac{12}{2} = 6 \quad S = \frac{mF}{n} = \frac{12}{3} = 4 \tag{8.7.152}$$

2. The octahedron $(m,n)=(3,4)$:

$$F=\frac{4n}{2n-mn+2m}=\frac{16}{8-12+6}=8 \quad A=\frac{mF}{2}=\frac{24}{2}=12 \quad S=\frac{mF}{n}=\frac{24}{2}=6 \tag{8.7.153}$$

3. The hexahedron or cube $(m,n)=(4,3)$:

$$F=\frac{4n}{2n-mn+2m}=\frac{16}{6-12+8}=6 \quad A=\frac{mF}{2}=\frac{24}{2}=12 \quad S=\frac{mF}{n}=\frac{24}{3}=6 \tag{8.7.154}$$

4. The icosahedron $(m,n)=(3,5)$:

$$F=\frac{4n}{2n-mn+2m}=\frac{20}{10-15+6}=20 \quad A=\frac{mF}{2}=\frac{60}{2}=30 \quad S=\frac{mF}{n}=\frac{60}{5}=12 \tag{8.7.155}$$

5. The dodecahedron $(m,n)=(5,3)$:

$$F=\frac{4n}{2n-mn+2m}=\frac{12}{6-15+10}=12 \quad A=\frac{mF}{2}=\frac{60}{2}=30 \quad S=\frac{mF}{n}=\frac{60}{3}=20 \tag{8.7.156}$$

this completes our classification.

Let us prove now that any polyhedron composed only of pentagons and hexagons has exactly mandatory twelve pentagons (and therefore there is no constraint on the number of hexagons). It is not a priori not very intuitive!

This proof will explain us for example why the soccer ball and the fullerene molecule have twelve pentagons:

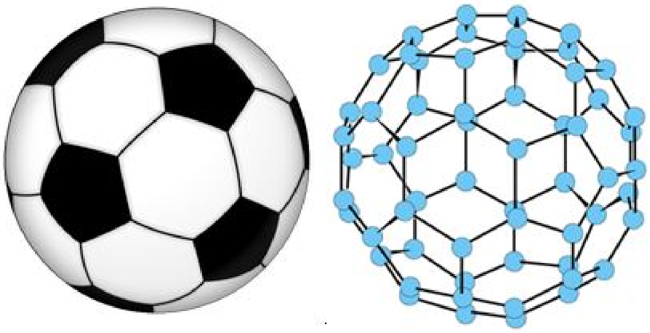


Figure 8.261: **Known polyhedra made of 12 pentagons**

Proof 8.27.2. For the proof, we start from the Euler's formula:

$$F-A+S=2 \tag{8.7.157}$$

Given M, the number of pentagons and N the number of hexagons, then we have the number of faces that is equal to:

$$F=M+N \tag{8.7.158}$$

In addition, each vertex is shared by three polygons in the case of the soccer ball and of the fullerene. Therefore, the number of vertices is equal to:

$$S=\frac{5M+6N}{3} \tag{8.7.159}$$

Each edge is shared by two polygons. Therefore, the number of edges is:

$$A=\frac{5M+6N}{2} \tag{8.7.160}$$

Then injecting Euler's formula:

$$\begin{aligned}F-A+S=2=(M+N)-\frac{5M+6N}{2}+\frac{5M+6N}{3}\\=\frac{6(M+N)-3(5M+6N)+2(5M+6N)}{6}=\frac{M}{6}\end{aligned} \tag{8.7.161}$$

Therefore, to satisfy:

$$\frac{M}{6}=2 \tag{8.7.162}$$

M, the number of pentagons, must be equal to 12.

■ Q.E.D.

8.7.2.1.5 Regular Tetrahedron

A tetrahedron is a polyhedron composed of 4 triangular faces, 6 straight edges, and 4 vertex corners. The tetrahedron is the simplest of all the ordinary convex polyhedra and the only one that has fewer than 5 faces.

The tetrahedron is one kind of pyramid, which is a polyhedron with a flat polygon base and triangular faces connecting the base to a common point. In the case of a tetrahedron the base is a triangle (any of the four faces can be considered the base), so a tetrahedron is also known as a "triangular pyramid".

Definition (#8.7.390): A "regular tetrahedron" is one in which all 4 faces are equilateral triangles. It is one of the five regular Platonic solids, which have been known since antiquity.

We have shown that for the tetrahedron $F=4,m=3$ and it is relatively easy to guess that such a polyhedron is formed by 3 identical equilateral triangles as shown in the figure below:

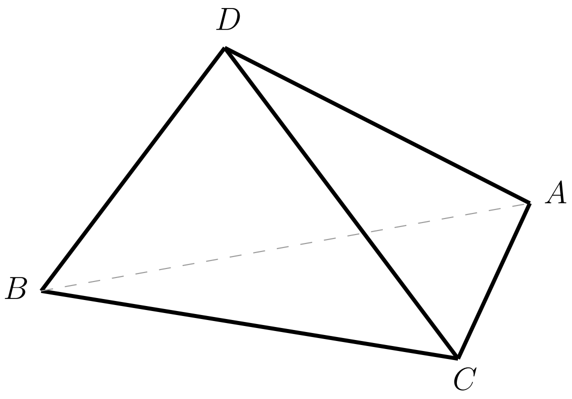

Figure 8.262: **Example of regular tetrahedron**

For this purpose let us start by studying the following equilateral triangle:

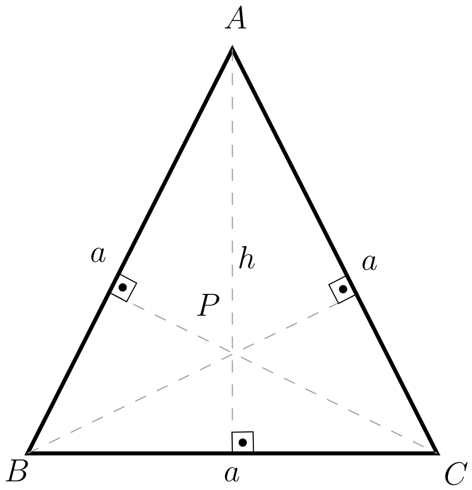

Figure 8.263: **Equilateral triangle to start with to calculate the volume of the tetrahedron**

In this equilateral triangle, a is the side, h is the height. The perpendicular bisectors are h, h', h'' of the respective sides $\overline{BC}$, $\overline{AB}$, $\overline{AC}$.

The segments h and h' intersect at a point P (barycenter). By construction of the equilateral triangle, we have $\overline{PC}=\overline{PB}=\overline{PA}$ (just apply Pythagoras theorem to prove it if you want).

Furthermore, we have already proved in our study of the triangle, that the barycenter of the latter is always at $2/3$ of the median height. As medians and bisectors are merged in the case of the equilateral triangle, then we have $\overline{AP}=2/3\cdot h$.

Now, if we draw a straight line passing through the point P and perpendicular to the plane in which the triangle is located. Given D a point on this line, as we have $\overline{PB}=\overline{PC}=\overline{PA}=2/3\cdot h$ we will have of course $\overline{BD}=\overline{AD}=\overline{CD}$ (again just apply Pythagoras theorem!).

We only have to find a way such that $\overline{BD}=a$ and we will have the regular tetrahedron we wanted. We then calculate:

$$\overline{BP}^2+\overline{PD}^2=\overline{BD}^2=a^2 \tag{8.7.163}$$

and therefore:

$$\overline{PD}^2=a^2-\left(\frac{2}{3}h\right)^2=a^2-\frac{4}{9}h^2=a^2-\frac{4}{9}\left(a^2-\left(\frac{1}{2}a\right)^2\right)=a^2-\frac{4}{9}\left(\frac{3}{4}a^2\right)=\frac{2}{3}a^2 \quad (8.7.164)$$

therefore:

$$H=\sqrt{\frac{2}{3}}a \quad (8.7.165)$$

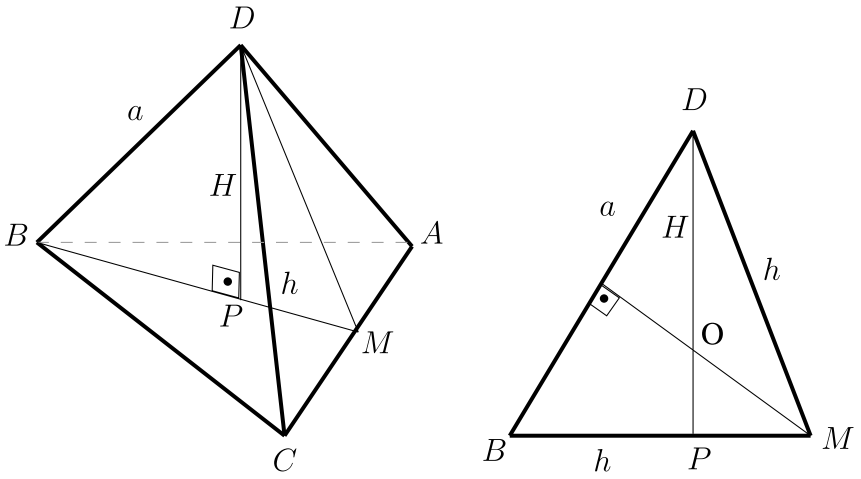

Figure 8.264: **Tetrahedron variables summary**

The bisector of $\overline{BD}$ (on the right figure) passing through M intersects H at a point O, which is nothing more than the center of the sphere circumscribed to the tetrahedron. Indeed, by construction, we have $\overline{\text{O}B}=\overline{\text{O}C}=\overline{\text{O}A}$ and the bisector gives us $\overline{\text{O}B}=\overline{\text{O}D}$.

The Thales theorem (see section Plane Geometry page 2610) also gives us:

$$\frac{\overline{\text{O}D}}{\frac{1}{2}a}=\frac{a}{\overline{PD}}\Rightarrow\overline{\text{O}D}=\frac{1}{2}a^2\frac{1}{\overline{PD}}=\frac{1}{2}a^2\frac{1}{\frac{\sqrt{2}}{\sqrt{2}}a}=\frac{\sqrt{3}}{\sqrt{2}}\frac{a}{2} \quad (8.7.166)$$

and for the developments that will follows we will put $H=\overline{PD}$, $\overline{\text{O}D}=R$.

Now let us calculate the total area. It will necessarily be given by the surface of one side multiplied by the number of faces, and as we have proved how to calculate the area of a triangle above it comes immediately:

$$S=n\left(\frac{1}{2}\cdot\text{basis}\cdot\text{height}\right)=4\frac{1}{2}ah=4\frac{1}{2}a\frac{\sqrt{3}a}{2}=\sqrt{3}a^2 \quad (8.7.167)$$

For the volume, it's also just as simple as we have proved earlier above that is was equal to that of a pyramid. It then comes immediately:

$$V=\frac{1}{3}\cdot\text{basis}\cdot\text{height}=\frac{1}{3}\frac{S}{4}\cdot H=\frac{1}{3}\frac{\sqrt{3}a^2}{4}\frac{\sqrt{2}}{\sqrt{3}}a=\frac{\sqrt{2}}{12}a^3 \quad (8.7.168)$$

Therefore:

$$\boxed{S=\sqrt{3}a^2} \tag{8.7.169}$$

and:

$$\boxed{V=\frac{\sqrt{2}}{12}a^3} \tag{8.7.170}$$

8.7.2.1.6 Regular hexahedron (cube)

The cube is a regular polyhedron that is probably the most familiar to us, it has 6 faces and its construction does not require to be presented.

The cube is also a square parallelepiped, an equilateral cuboid and a right rhombohedron. It is a regular square prism in three orientations, and a trigonal trapezohedron in four orientations.

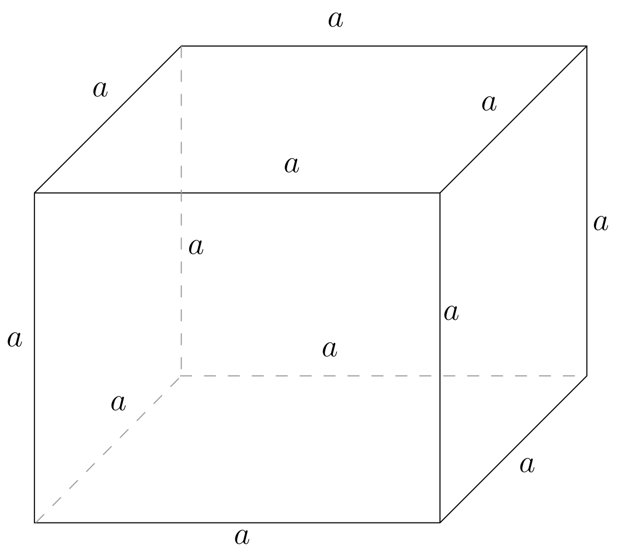

Figure 8.265: Example of regular hexahedron (cube)

Since all sides are of length a, the surface is simply given by the multiplication of the 6 faces surfaces. So:

$$\boxed{S=6a^2} \tag{8.7.171}$$

and the volume:

$$\boxed{V=a^3} \tag{8.7.172}$$

8.7.2.1.7 Regular octahedron

We have shown that for the octahedron $F=8, m=4$ and it is relatively easy to guess that the regular octahedron is formed (by definition!!!) of 8 identical equilateral triangles.

A regular octahedron is a square bi-pyramid in any of three orthogonal orientations. It is also a triangular anti-prism in any of four orientations.

To build, and demonstrate that it is possible to build such a polyhedron, we put as before that his side is equal to a:

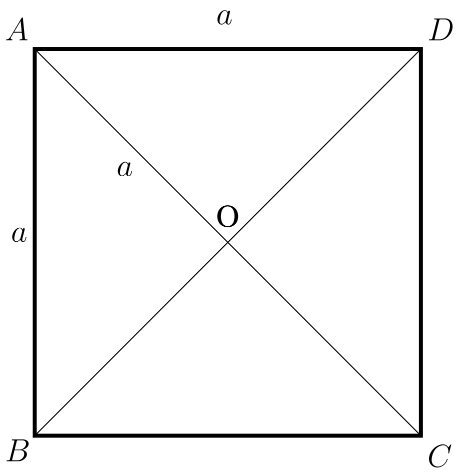

Figure 8.266: Example of regular octahedron seen from above

Then we denote by O the point of intersection of the two diagonals. We have therefore by applying the Pythagorean theorem:

$$\overline{AC}^2=a^2+a^2=2a^2 \Rightarrow \overline{AC}=\sqrt{2}a \tag{8.7.173}$$

and:

$$\overline{\text{O}A}^2=\frac{1}{2}\overline{AC}=\frac{a}{\sqrt{2}} \tag{8.7.174}$$

On the perpendicular line to the plane containing our square, and passing through O, we add two vertices E, F at a distance that we calculate as follows:

$$\overline{\text{O}A}^2+\overline{\text{O}E}^2=\overline{AE}^2=a^2 \tag{8.7.175}$$

from which we get:

$$\overline{\text{O}E}^2=\overline{AE}^2-\overline{\text{O}A}^2=a^2-\frac{1}{2}a^2=\frac{1}{2}a^2 \tag{8.7.176}$$

Therefore:

$$\overline{\text{O}E}^2=\frac{a}{\sqrt{2}}=\overline{\text{O}A}=-\overline{\text{O}F} \tag{8.7.177}$$

Our polyhedron is then well formed by 8 equilateral identical triangles. Each vertex has 4 corners and 4 faces, which allows us to affirm that it is regular and so ends our construction.

The surface of the regular octahedron is:

$$S=n\frac{1}{2}ah=8\frac{1}{2}a\frac{\sqrt{3}a}{2}=2\sqrt{3}a^2 \tag{8.7.178}$$

where h is the height of the equilateral triangle of side a that we have already calculated above.

For the volume, this is still based on that of the pyramid. So:

$$V=2\frac{1}{3}\text{basis}\cdot\text{height}=2\frac{1}{3}a^2\frac{a}{\sqrt{2}}=\frac{\sqrt{2}}{3}a^2 \tag{8.7.179}$$

And we will assume that it is obvious to the reader that our octahedron is inscribed in a sphere of radius R whose center is the point O. For R, we have:

$$R=\overline{\text{O}A}=\overline{\text{O}E}=\frac{a}{\sqrt{2}} \tag{8.7.180}$$

Let us show already that now we can build the regular icosahedron from the octahedron and this latter exists and is buildable.

For this purpose, we will first consider a reference frame of the octahedron placed at the origin O corresponding to its barycenter as visible in the figure below:

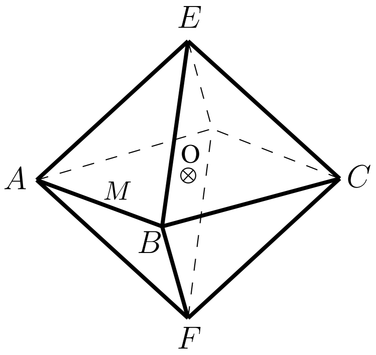

Figure 8.267: **Example of the octahedron**

We then have:

$$\begin{aligned}\vec{A}&=(R,0,0)\\ \vec{B}&=(0,R,0)\\ \vec{C}&=(-R,0,0)\\ \vec{D}&=(0,-R,0)\\ \vec{E}&=(0,0,R)\\ \vec{F}&=(0,0,-R)\end{aligned} \tag{8.7.181}$$

After this, let us consider the following figure:

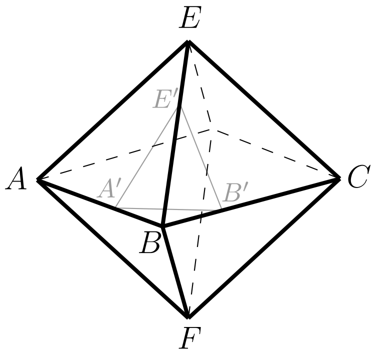

Figure 8.268: Searches of the position of the equilateral triangle

In the figure above, A' is a point that start from A and that arrives in B, and given B' a point which start from C and arrives at B, and finally E' a point that start from B and arrives on E. These three points go together and moving at the same speed. If we follow these three points that form a triangle $A'B'E'$, we feel intuitively that there is a place such that $A'B'E'$ is an equilateral triangle.

Let us determine this place:

$$\begin{aligned}\overrightarrow{AB}&=\overrightarrow{\mathrm{O}B}-\overrightarrow{\mathrm{O}A}=(-R,R,0) & \overrightarrow{\mathrm{O}A'}&=\overrightarrow{\mathrm{O}A}+\mu\overrightarrow{AB}=R(1-\mu,\mu,0)\\ \overrightarrow{CB}&=\overrightarrow{\mathrm{O}B}-\overrightarrow{\mathrm{O}C}=(R,R,0) & \overrightarrow{\mathrm{O}B'}&=\overrightarrow{\mathrm{O}C}+\mu\overrightarrow{CB}=R(\mu-1,\mu,0)\\ \overrightarrow{BE}&=\overrightarrow{\mathrm{O}E}-\overrightarrow{\mathrm{O}B}=(0,-R,R) & \overrightarrow{\mathrm{O}E'}&=\overrightarrow{\mathrm{O}B}+\mu\overrightarrow{BE}=R(0,1-\mu,\mu)\end{aligned} \tag{8.7.182}$$

and therefore:

$$\begin{aligned}\overrightarrow{A'B'}&=\overrightarrow{\mathrm{O}B'}-\overrightarrow{\mathrm{O}A'}=R(2\mu-2,0,0)\\ \overrightarrow{A'E'}&=\overrightarrow{\mathrm{O}E'}-\overrightarrow{\mathrm{O}A'}=R(\mu-1,1-2\mu,\mu)\end{aligned} \tag{8.7.183}$$

and we want:

$$||\overrightarrow{A'B'}||=||\overrightarrow{A'E'}||=||\overrightarrow{B'E'}|| \tag{8.7.184}$$

Therefore:

$$||\overrightarrow{A'B'}||^2=R^2(2\mu-2)^2=||\overrightarrow{A'E'}||^2=R^2\left[(\mu-1)^2+(1-2\mu)^2+\mu^2\right] \tag{8.7.185}$$

That is to say:

$$4\mu^2-8\mu+4=6\mu^2-6\mu+2 \tag{8.7.186}$$

Which simplifies in:

$$\mu^2-\mu-1=0 \tag{8.7.187}$$

and as $0\leq\mu\leq 1$, we get for the resolution of this polynomial of the second degree (see section Calculus page 1382) the only acceptable solution:

$$\mu=\frac{1}{2}(-1+\sqrt{5}) \tag{8.7.188}$$

where the reader may have perhaps noticed that this is the inverse of the golden ratio...

According to the figure below, if we put:

$$\overrightarrow{\text{O}I'}=\overrightarrow{\text{O}E}+\mu\overrightarrow{EA} \tag{8.7.189}$$

then we fall back on the same value for μ (the reader can check this himself, or we can on request add the detailed calculations here) and ditto for all other points:

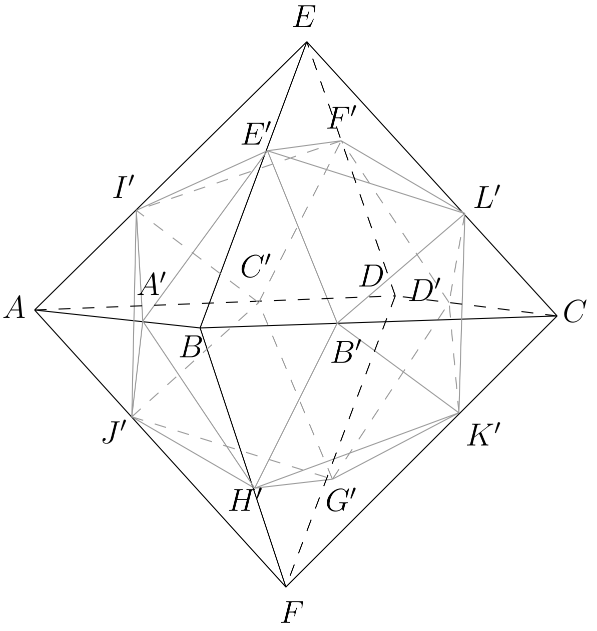

Figure 8.269: **Construction of a regular icosahedron**

Our new polyhedron therefore has one face by face of the octahedron and one face by edge of the octahedron. We have therefore 20 faces composed of identical equilateral triangles. In addition, 5 edges and 5 faces meet at each vertices. We then get a regular icosahedron!!!

We then have for the coordinates of each vertex (the reader must be observed that the vertices are opposed in pairs one component on the figure):

$$\begin{array}{ll}
\vec{A}'=R(1-\mu,\mu,0) & \vec{D}'=R(1-\mu,-\mu,0)\\
\vec{B}'=R(\mu-1,\mu,0) & \vec{C}'=R(1-\mu,-\mu,0)\\
\vec{E}'=R(0,1-\mu,\mu) & \vec{H}'=R(0,1-\mu,-\mu)\\
\vec{F}'=R(0,\mu-1,\mu) & \vec{G}'=R(0,\mu-1,-\mu)\\
\vec{I}'=R(\mu,0,1-\mu) & \vec{L}'=R(-\mu,0,1-\mu)\\
\vec{J}'=R(\mu,0,\mu-1) & \vec{K}'=R(-\mu,0,1-\mu)
\end{array} \tag{8.7.190}$$

8.7.2.1.8 Regular Icosahedron

We saw earlier how to build the regular icosahedron. There it exists!

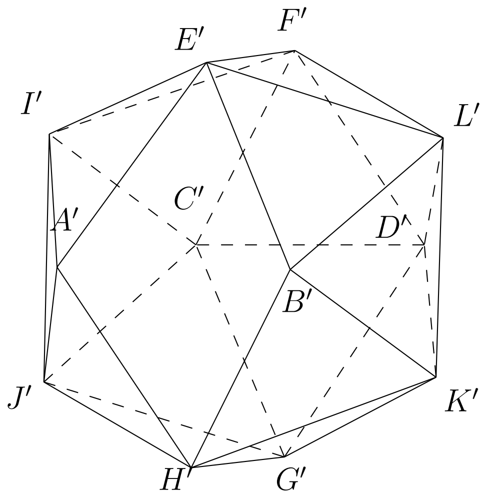

Figure 8.270: **Representation of the regular icosahedron**

Knowing the coordinates of the different edges, let us now calculate the surface and volume of the regular icosahedron.

The calculation of the surface is simple since it is 20 equilateral triangles. We have then:

$$\overrightarrow{A'B'} = R(2\mu - 2, 0, 0) \tag{8.7.191}$$

therefore:

$$||\overrightarrow{A'B'}|| = 2R(\mu - 1) = a' \tag{8.7.192}$$

Hence:

$$S = 20\frac{1}{2}a'h = 20\frac{1}{2}a'\sqrt{a'^2 - \left(\frac{1}{2}a'\right)^2} = 20\frac{1}{2}a'2\sqrt{\frac{3}{4}a'^2} = 20\frac{1}{2}a'\frac{\sqrt{3}}{2}a' \tag{8.7.193}$$

Therefore:

$$\boxed{S = 5\sqrt{3}a'^2} \tag{8.7.194}$$

The calculation of the volume being quite more subtle! Let's go for it...

The icosahedron is built around the pentagon and the golden section as we were able to notice in our previous study of the octahedron.

If ever the reader is not convinced here is an additional figure where we see that each edge of the icosahedron is an edge of a pentagon ($AFECB$, $LGHJK$, $DAJKC$, $DEGHA$, $BJILC$, $FELIH$,...):

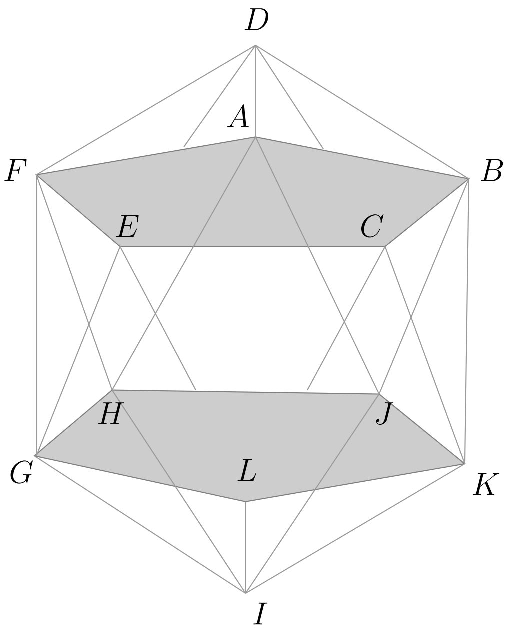

Figure 8.271: **Pentagons in the regular icosahedron**

Using the method of the pyramids, we have 20 equilateral triangles that form the basis of a pyramid whose height goes up to the origin O of the icosahedron (or the origin confused the with circumscribed or inscribed corresponding sphere).

Take for example the base ABD with the intersection of mediators located at the point M as shown below:

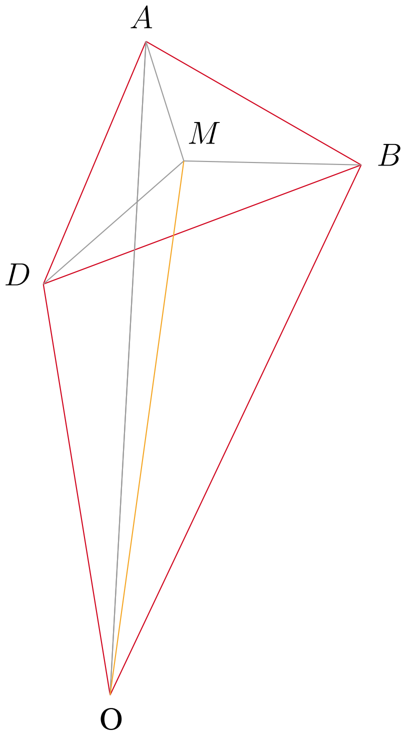

Figure 8.272: **Representation of one of the pyramids of the regular icosahedron**

As we know, we proved that the volume of a pyramid is:

$$V_p = \frac{1}{3}bh \tag{8.7.195}$$

The surface b in our situation that of the equilateral triangle ΔADB and the height h is the segment $\overline{\text{O}M}$.

If we denote by a the triangle side, then the surface is given by:

$$S = \frac{ah}{2} = \frac{a\sqrt{a^2 - \left(\frac{1}{2}a\right)^2}}{a} = \frac{\sqrt{3}}{4}a^2 \tag{8.7.196}$$

To find h, we know by construction of the point M that the triangles $\text{O}MA$, $\text{O}MB$ and $\text{O}MD$ are right triangles.

Let us work arbitrarily with the triangle $\text{O}MD$. First, let determine the length $\overline{DM}$. We have proved in our study of the bisector of length H of the equilateral triangle (see section Euclidean Geometry page 2601) that $\overline{DM}$ is then equal to:

$$\overline{DM} = \frac{2}{3}H \tag{8.7.197}$$

But:

$$H = \sqrt{a^2 - \left(\frac{1}{2}a\right)^2} = \frac{\sqrt{3}}{2}a \tag{8.7.198}$$

So finally:

$$\overline{DM} = \frac{2}{3}\frac{\sqrt{3}}{2}a = \frac{\sqrt{3}}{3}a = \frac{1}{\sqrt{3}}a \tag{8.7.199}$$

To find h we must find the length $\overline{\text{O}D} = r$ in terms of length of the edges a of icosahedron. For this, we must recognize one of the fundamental properties of the icosahedron.

Before going further, let us show a property of the pentagon below with its diagonals d and sides c:

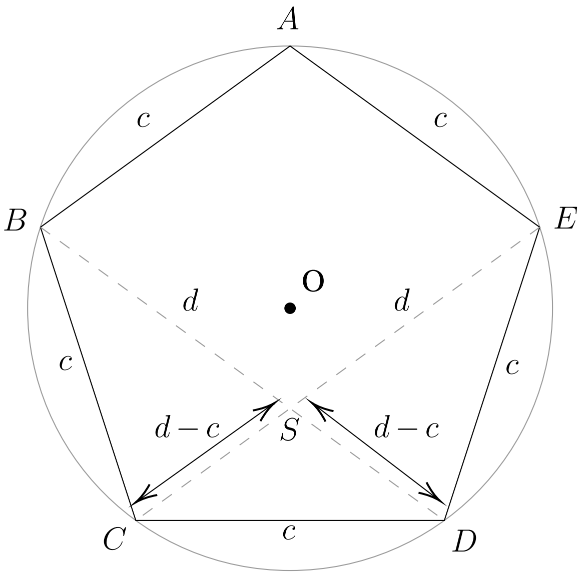

Figure 8.273: **Parallelogram in a pentagon**

$BSEA$ is a parallelogram. Indeed, the diagonal $\overline{BD}$ is parallel to the side $\overline{AE}$ (for example, because both are perpendicular to the axis of symmetry passing through $\overline{\text{O}C}$). Since S is on $\overline{BD}$, it proves that $\overline{BS}$ and $\overline{AE}$ are parallel. We show in the same manner that $\overline{AB}$ and $\overline{SE}$ are parallel.

We deduce that:

$$\overline{SD}=\overline{BD}-\overline{BS}=\overline{BD}-\overline{AE}=d-c \qquad (8.7.200)$$

and same for $\overline{CS}$:

$$\overline{CS}=\overline{EC}-\overline{ES}=\overline{EC}-\overline{AB}=d-c \qquad (8.7.201)$$

Let us continue ... we have the equality $\widehat{BAE}=\widehat{CSD}$. Furthermore, as CD and BE are parallel, the triangles SCD and ABE are similar. Therefore, the distances between their sides are kept (Thales):

$$\frac{\overline{AE}}{\overline{BE}}=\frac{\overline{SD}}{\overline{CD}} \qquad (8.7.202)$$

hence the relation:

$$\frac{c}{d}=\frac{d-c}{c} \qquad (8.7.203)$$

After some modifications:

$$\frac{d}{c}-\frac{c}{d-c}=0\Leftrightarrow\frac{d(d-c)-c\cdot c}{c(d-c)}=0\Leftrightarrow d^2-dc-c^2=0\Leftrightarrow\frac{d^2}{c^2}-\frac{d}{c}-1=0 \qquad (8.7.204)$$

If μ now designates the ratio d/c, the above relation becomes:

$$\mu^2-\mu-1=0 \qquad (8.7.205)$$

and μ being strictly positive, we have already seen during our study of the octahedron that the only positive root is the golden ratio:

$$\mu=\frac{d}{c}=\frac{1+\sqrt{5}}{2} \qquad (8.7.206)$$

We have just finish to prove that a diagonal of a pentagon is equal to the golden ratio multiplied by the length of an edge of this same pentagon.

Thus we have in the pentagons $AFECB$ and $LGHJK$ of our icosahedron:

$$\overline{FB}=\overline{GK}=\mu a \qquad (8.7.207)$$

Let us notice also the rectangle $FBGK$ whose barycenter (centroid) coincides with that of the icosahedron. Moreover, $\overline{FK}$ and $\overline{BG}$ represent by construction the diameter of the sphere circumscribed to the icosahedron and therefore $\overline{OF}=\overline{OK}$ is the radius r that we are looking for.

We have:

$$\overline{FK}^2=\overline{FB}^2+\overline{BK}^2=\mu^2a^2+a^2=(\mu^2+1)a^2 \qquad (8.7.208)$$

Therefore:

$$\overline{FK} = a\sqrt{\mu^2+1} = 2r \tag{8.7.209}$$

hence:

$$r = \frac{a\sqrt{\mu^2+1}}{2} \tag{8.7.210}$$

Now, we can calculate h:

$$h^2 = \overline{OM}^2 = r^2 - \overline{DM}^2 = \frac{a^2(\mu^2+1)}{4} - \frac{1}{3}a^2 = \frac{3(\mu^2+1)-4}{12}a^2 = \frac{3\mu^2-1}{12}a^2 \tag{8.7.211}$$

But:

$$\mu^2 = \left(\frac{1+\sqrt{5}}{2}\right)^2 = \frac{6+2\sqrt{5}}{4} = \mu+1 \tag{8.7.212}$$

as the golden ratio is a root of $x^2 = x+1$.

Therefore:

$$(\mu^2)^2 = (\mu+1)^2 = \mu^2+2\mu+1 = \mu^2+2(\mu^2-1)+1 = 3\mu^2-1 \tag{8.7.213}$$

Finally:

$$h^2 = \frac{3\mu^2-1}{12}a^2 = \frac{\mu^4}{12}a^2 \tag{8.7.214}$$

and:

$$h = \frac{\mu^2}{2\sqrt{3}}a \tag{8.7.215}$$

Therefore the volume of one pyramid of the icosahedron is:

$$V_{\text{pyr}} = \frac{1}{3}Sh = \frac{1}{3}\frac{\sqrt{3}}{4}a^2\frac{\mu^2}{2\sqrt{3}}a = \frac{\mu^2}{24}a^3 \tag{8.7.216}$$

As the are 20 pyramids:

$$\boxed{V = 20\frac{\mu^2}{24}a^3 = \frac{5}{6}\mu^2a^3} \tag{8.7.217}$$

8.7.2.1.9 Regular Dodecahedron

After failing to find in the literature an aesthetic and simple way the of the proof of the construction feasibility of the dodecahedron, we will move in for now (it is possible to live without it...).

Let us simply notice that the dodecahedron consists of 12 pentagons and its volume is comparable to that of a cube on which we have placed on each face a sort of little roof which ultimately will give the pentagons:

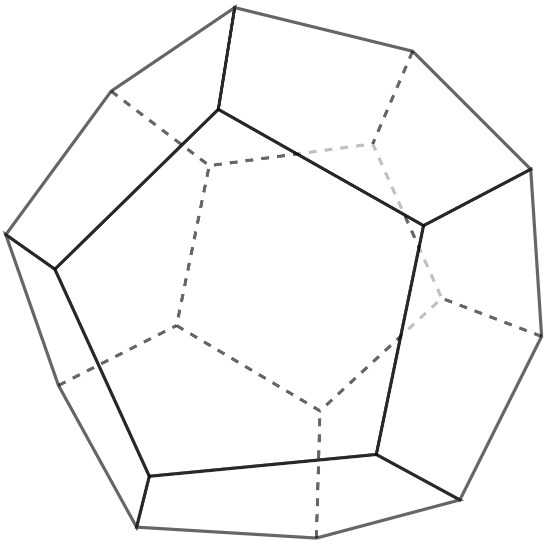

Figure 8.274: **Regular dodecahedron**

For our study of the dodecahedron, we will only focus to determine its surface and volume.

For this, let us consider first the regular pentagon below:

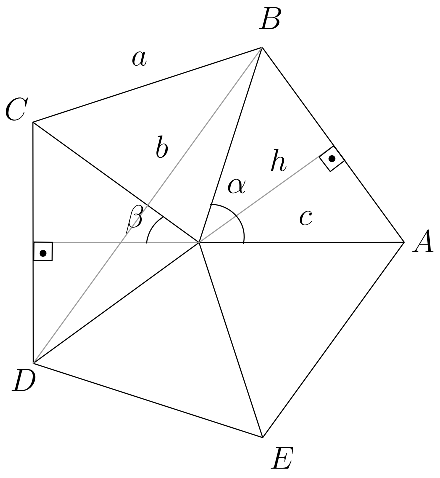

Figure 8.275: **Regular pentagon for the study of the volume of the regular dodecahedron**

We will first have to determine the length of h and b.

Let us first recall that we have already during our study of the icosahedron proved that the diagonal of a pentagon is connected to the length of its sides by the relation:

$$b = a\mu = a\frac{1+\sqrt{5}}{2} \tag{8.7.218}$$

where μ is the golden ratio. It remains to then to determine h.

It is obvious first that $\beta = 2\pi/10 = \pi/5 = \alpha/2$ and that:

$$c \cdot \cos(\beta) = h \tag{8.7.219}$$

But we have two missing information here: the angle and c. Begin by determining how much is the cosine without using the calculator (you will understand why ...).

We have first by the identity (see section Trigonometry page 2519):

$$\cos(2x)=2\cos^2(x)-1 \tag{8.7.220}$$

that:

$$\cos\left(4\frac{\pi}{5}\right)=2\cos^2\left(2\frac{\pi}{5}\right)-1 \tag{8.7.221}$$

Which can also be written:

$$\cos\left(\pi-\frac{\pi}{5}\right)=2\cos^2\left(2\frac{\pi}{5}\right)-1 \tag{8.7.222}$$

But this can also be written always using the same trigonometric identity:

$$\cos\left(\pi-\frac{\pi}{5}\right)=2\left[2\cos^2\left(\frac{\pi}{5}\right)-1\right]-1 \tag{8.7.223}$$

Thus after simplification:

$$-\cos\left(\frac{\pi}{5}\right)=8\cos^4\left(\frac{\pi}{5}\right)-8\cos^2\left(\frac{\pi}{5}\right)+1 \tag{8.7.224}$$

By a change of variable and rearranging the different terms:

$$8X^4-8X^2+X+1=0 \tag{8.7.225}$$

We have -1 and $1/2$ that are two obvious roots so we get (see section Calculus page 1383):

$$(X+1)\left(X-\frac{1}{2}\right)\left(X^2-\frac{1}{2}X-\frac{1}{4}\right)=0 \tag{8.7.226}$$

We just have to solve a simple equation of the second degree, the solution is trivial using the methods seen in the section Calculus and we get:

$$X=\frac{1\pm\sqrt{5}}{4} \tag{8.7.227}$$

Either by taking the only feasible solution, then we have:

$$X=\frac{\mu}{2}=\frac{1+\sqrt{5}}{4} \tag{8.7.228}$$

So we fall back on the golden ratio again! and this leads us directly to write:

$$\boxed{h=\frac{1}{2}\mu c=\frac{1}{2}\frac{1+\sqrt{5}}{2}c} \tag{8.7.229}$$

It remains to us to determine c. We have:

$$\left(\frac{1}{2}a\right)^2+h^2=c^2\frac{1}{4}a^2+\frac{1}{4}\mu^2c^2\Rightarrow c^2(4-\mu^2)=a^2 \tag{8.7.230}$$

and as $\mu^2-\mu-1=0$ we have:

$$\begin{aligned}&(4-\mu^2)(2+\mu)=8+4\mu-2\mu^2-\mu^3=8+4\mu-2\mu^2-\mu(\mu+1)=8+3\mu-3\mu^2\\&=8+3(\mu-\mu^2)=8+3(-1)=5\end{aligned}\tag{8.7.231}$$

and therefore:

$$c^2=\frac{1}{4-\mu^2}a^2=\frac{2+\mu}{5}a^2=\frac{\mu^2+1}{5}a^2\tag{8.7.232}$$

hence:

$$c=\frac{\sqrt{\mu^2+1}}{\sqrt{5}}a\tag{8.7.233}$$

We have therefore for the calculation of the area of the dodecahedron, a surface composed of 12 pentagons, each of which is composed of by 5 triangle of base a and height h:

$$\begin{aligned}S&=12\cdot 5\frac{1}{2}ah=30ah=30a\frac{1}{2}\mu c=15a\mu c=15a\mu\frac{\sqrt{\mu^2+1}}{\sqrt{5}}a\\&=15\mu\frac{\sqrt{\mu^2+1}}{\sqrt{5}}a^2\end{aligned}\tag{8.7.234}$$

Therefore:

$$\boxed{S=3\mu a^2\sqrt{5}\sqrt{\mu^2+1}}\tag{8.7.235}$$

To calculate the volume, we're going to use the trick mentioned at the beginning. That is to say to cut in a first time the dodecahedron in a parallelepiped of side:

$$c=s\mu=s\frac{1+\sqrt{5}}{2}\tag{8.7.236}$$

since the side of the parallelepiped is a diagonal of the pentagon of side s and of 6 small roofs (which are clearly visible on the figure previously given of the dodecahedron).

Every little roof following two different views have the following lengths (where we fall back obviously for some edges those of pentagons s or the diagonals c thereof):

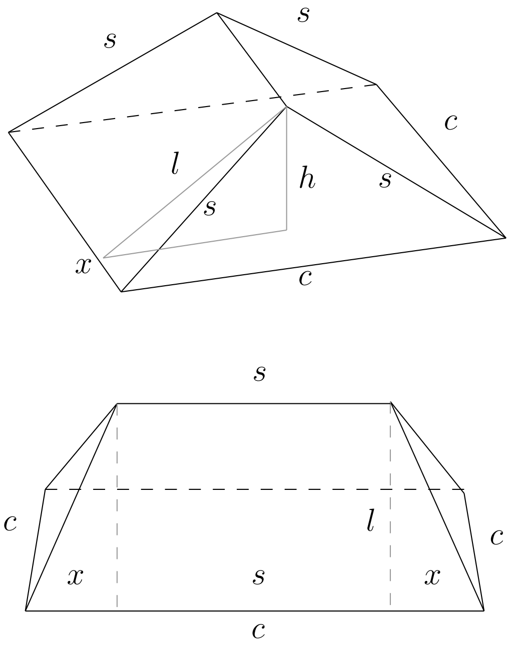

Figure 8.276: **Dodecahedron roofs**

Each small roof, we treat separately their ends by separating (cutting) them and merging them together. Finally, we have two pieces to study: the major visible part of the roof left in the figure below and the secondary part of the roof on the right in the figure below, which is nothing else other than the merging of the extremities of one small roof:

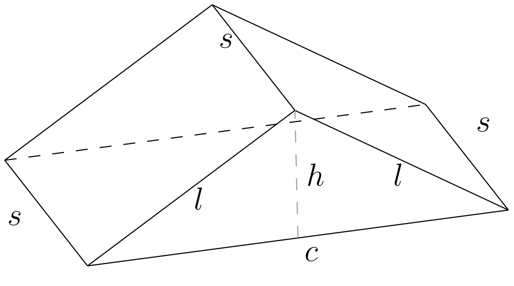

Figure 8.277: **Dodecahedron roofs decomposition for volume calculation**

We must therefore determine x and l and h since c and s are already known to us.

First, we see trivially that:

$$x=\frac{c-s}{2} \tag{8.7.237}$$

From the Pythagorean theorem, we then have:

$$\begin{aligned}&s^2=l^2+x^2=l^2+\left(\frac{c-s}{2}\right)^2\\&l^2=h^2+\left(\frac{c}{2}\right)^2\end{aligned} \tag{8.7.238}$$

Combining these two relationships, we get:

$$s^2-\left(\frac{c-s}{2}\right)^2=h^2+\left(\frac{c}{2}\right)^2 \tag{8.7.239}$$

Therefore it comes:

$$\begin{aligned}h^2&=s^2-\left(\frac{c-s}{2}\right)^2-\left(\frac{c}{2}\right)^2=s^2-\frac{1}{4}(c^2-2cs+s^2)-\frac{c^2}{4}=\frac{3}{4}s^2-\frac{c^2}{2}+\frac{cs}{2}\\&=\frac{3}{4}s^2-\frac{\left(\dfrac{1+\sqrt{5}}{2}s\right)^2}{2}+\frac{\left(\dfrac{1+\sqrt{5}}{2}s\right)s}{2}=\frac{3}{4}s^2-\frac{(1+\sqrt{5})^2s^2}{8}+\frac{(1+\sqrt{5})s^2}{4}\\&=s^2\left(\frac{3}{4}-\frac{(1+\sqrt{5})^2}{8}+\frac{(1+\sqrt{5})}{4}\right)=s^2\left(\frac{6-1-2\sqrt{5}-5+2+2\sqrt{5}}{8}\right)=s^2\frac{2}{8}=\frac{1}{4}s^2\end{aligned} \tag{8.7.240}$$

Hence:

$$h=\frac{s}{2} \tag{8.7.241}$$

We can now calculate the volume V_p of the 6 small roofs:

$$\begin{aligned}V_p&=6\left(\frac{1}{3}2xch+\frac{csh}{2}\right)=6\left(\frac{1}{3}2\frac{c-s}{2}c\frac{s}{2}+\frac{cs}{2}\frac{s}{2}\right)\\&=6\left(\frac{1}{3}\left(s\frac{1+\sqrt{5}}{2}-s\right)s\frac{1+\sqrt{5}}{2}\frac{s}{2}+s\frac{1+\sqrt{5}}{2}\frac{s^2}{4}\right)\\&=s^3\left(\left(\frac{1+\sqrt{5}}{2}-1\right)\frac{1+\sqrt{5}}{2}+3\frac{1+\sqrt{5}}{2}\right)=s^3\left(\frac{(1+\sqrt{5}-2)(1+\sqrt{5})}{4}+\frac{3+3\sqrt{5}}{3}\right)\\&=s^3\left(\frac{(1+\sqrt{5}-2)(1+\sqrt{5})+3+3\sqrt{5}}{4}\right)=s^3\left(\frac{(1+\sqrt{5}-2+\sqrt{5}+5-2\sqrt{5})+3+3\sqrt{5}}{4}\right)\\&=s^3\left(\frac{7+3\sqrt{5}}{4}\right)\end{aligned} \tag{8.7.242}$$

Therefore, the total volume of the dodecahedron is finally the volume of 6 small roofs summed with the volume of the central parallelepiped:

$$\begin{aligned}V&=c^3+s^3\left(\frac{7+3\sqrt{5}}{4}\right)=\left(\frac{1+\sqrt{5}}{2}\right)^3+s^3\left(\frac{7+3\sqrt{5}}{4}\right)=s^3\left[\left(\frac{7+3\sqrt{5}}{4}\right)+\left(\frac{1+\sqrt{5}}{2}\right)^3\right]\\&=s^3\left[\left(\frac{7+3\sqrt{5}}{4}\right)+\frac{1}{8}(1+\sqrt{5})^3\right]=s^3\left[\frac{7+3\sqrt{5}}{4}+\frac{1}{8}(1+3\sqrt{5}+3\cdot 5+5\sqrt{5})\right]\\&=s^3\left[\frac{7+3\sqrt{5}}{4}+\frac{1}{8}(16+8\sqrt{5})\right]=s^3\left[\frac{7+3\sqrt{5}}{4}+\frac{1}{4}(8+4\sqrt{5})\right]=s^3\frac{15+7\sqrt{5}}{4}\end{aligned} \tag{8.7.243}$$

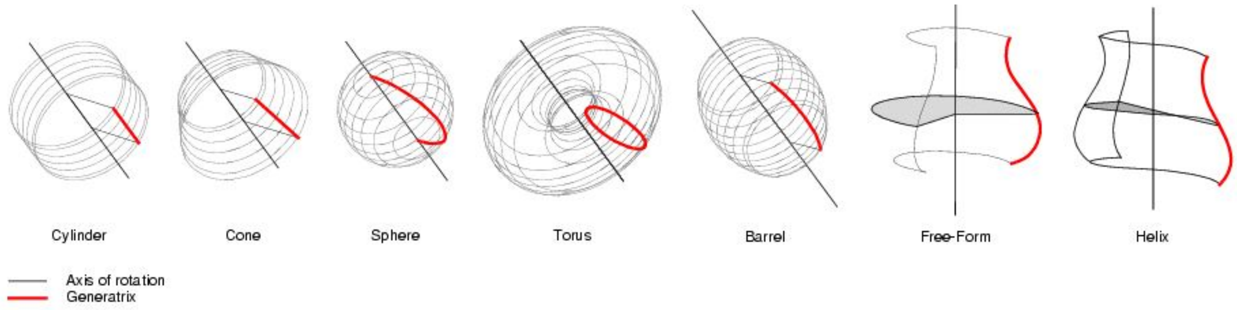
Finally:

$$\boxed{V=s^3\frac{15+7\sqrt{5}}{4}} \tag{8.7.244}$$

8.7.2.2 Usual Solids of Revolution

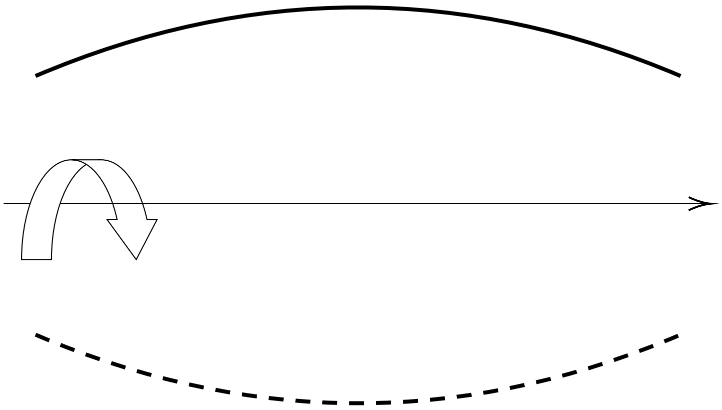
Let us recall that as seen in the section of Analytical Geometry a "solid of revolution" is a solid figure obtained by rotating a plane curve around some straight line (the axis) that lies on the same plane. and the more formally a surface of revolution is a surface obtained by rotating a plane curve (e.g. $y=f(x)$), named the "generatrix", around the y-axis (for example!). So we pass from a plane of $\mathbb{R}^2$ to a basis in $\mathbb{R}^3$.

Indeed many surfaces (and also some of which we've seen in the section of Analytical Geometry as the sphere, tore and cylinder) can be described by revolving a primary form of smaller size and then by rotation.



Cylinder
Cone
Sphere
Torus
Barrel
Free-Form
Helix
Axis of rotation
Generatrix

Let us see before going further a general method for determining the area of a body of revolution. That is to say the surface of the body generated by the rotation of a finite length curve about an axis:

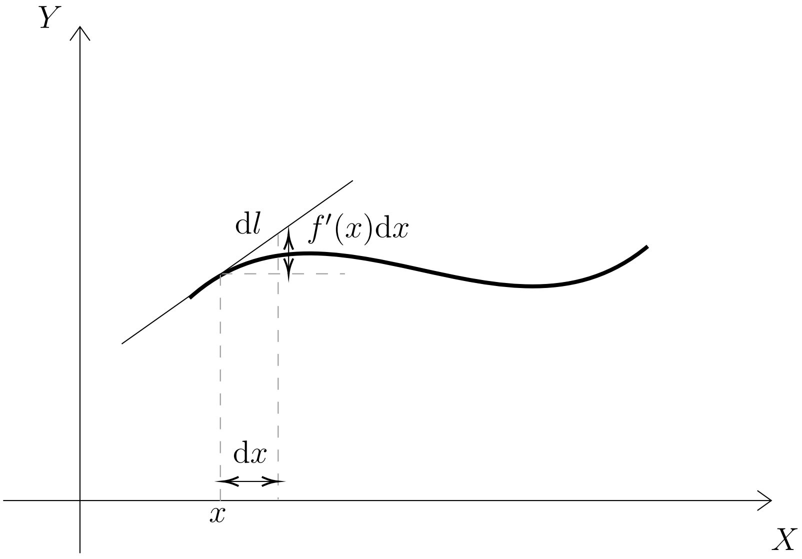


For this, we notice that when the curve is given a function $y=f(x)$ and we notice by Pythagoras (see figure below) that the element of length $\mathrm{d}l$ satisfies (relation that we have already meet in other sections of this textbook):

$$\mathrm{d}l^2=\mathrm{d}x^2+\mathrm{d}y^2=\mathrm{d}x^2+(f'(x))^2\mathrm{d}x^2 \tag{8.7.245}$$

Therefore:

$$\mathrm{d}l=\sqrt{1+(f'(x))^2}\mathrm{d}x^2 \tag{8.7.246}$$



Thus, the surface element generated by the rotation of the element of length $\mathrm{d}l$ is given by:

$$\mathrm{d}S = 2\pi|f(x)|\mathrm{d}l = 2\pi|f(x)|\sqrt{1+(f'(x))^2}\mathrm{d}x^2 \qquad (8.7.247)$$

The area of the surface of revolution generated by a function $f:[a,b]\mapsto\mathbb{R}$ continuously differentiable is then given by the relation:

$$\boxed{S = 2\pi\int\limits_a^b |f(x)|\sqrt{1+(f'(x))^2}\mathrm{d}x^2} \qquad (8.7.248)$$

Remark

In the section Mechanics we will use another approach that can be used to calculate the surface (and volume) of bodies of revolution and that is named "Pappus's second centroid Theorem". In fact as we will see, it is more used in practice to determine the centroid position rather than the surface (or volume) of a body of revolution.

8.7.2.2.1 Cylinder

Definition (#8.7.391): A "cylinder" is a surface generated by a line moving parallel to a fixed direction by meeting a fixed plane curve (circle), which plane cuts the given direction.

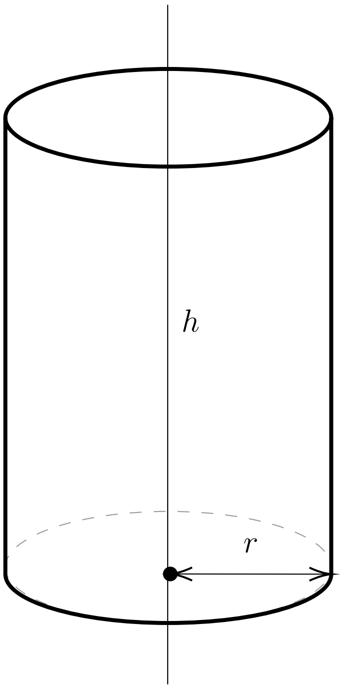


Figure 8.278: **Example of a cylinder**

The volume of a cylinder of revolution of height $x = r$ and height h is calculated by the method of discs knowing that the surface of a circle (disc) is πr^2:

$$V = \pi r^2 \int_0^h \mathrm{d}y = \pi r^2 y \Big|_0^h = \pi r^2 h \tag{8.7.249}$$

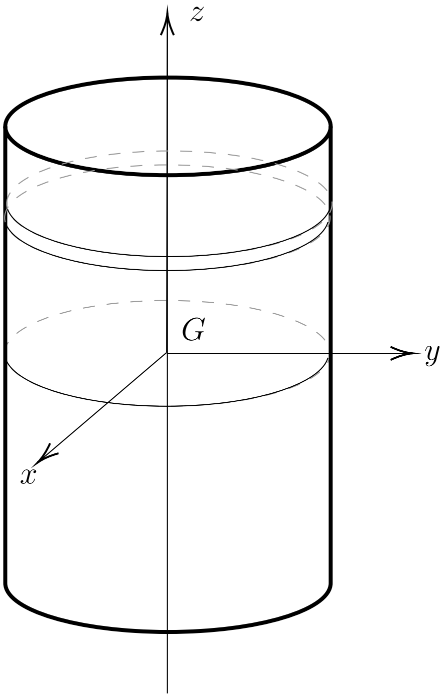
Therefore:

$$\boxed{V = \pi r^2 h} \tag{8.7.250}$$

The surface of a cylinder is simply the sum of the surface of the both discs and of the surface of the folded rectangle of height h and length of $2\pi r$:

$$\boxed{S = 2(\pi r^2) + 2\pi r h} \tag{8.7.251}$$

Now let us calculate the moment of inertia of a solid cylinder with respect to its vertical symmetry axis (revolution axis):



We have:

$$\mathrm{d}m=\rho\mathrm{d}V=\rho 2\pi rh\mathrm{d}r \tag{8.7.252}$$

Therefore:

$$J_z=\int r^2\mathrm{d}m=\int \rho r^2 2\pi rh\mathrm{d}r=2\pi\rho h\int\limits_0^R\int\limits_0^R r^3\mathrm{d}r=2\pi\rho h\frac{R^4}{4}=\rho\pi R^2 h\frac{R^2}{2}=M\frac{R^2}{2} \tag{8.7.253}$$

Given now G the cylinder's center of gravity, G_z coincides with the cylinder axis of the revolution. The axes G_y and G_x play identical roles. The moments of inertia J_{G_x} and J_{G_y} with respect to these axes are equal and are written:

$$J_{G_y}=\int(x^2+z^2)\mathrm{d}m=J_{G_x}=\int(y^2+z^2)\mathrm{d}m=J \tag{8.7.254}$$

hence:

$$J_{G_y}+J_{G_x}=2J_{G_x}=2J_{G_y}=\int(x^2+z^2+y^2+z^2)\mathrm{d}m=\int(x^2+y^2+2z^2)\mathrm{d}m \tag{8.7.255}$$

hence:

$$J_{G_y}=J_{G_x}=\frac{1}{2}(x^2+y^2+2z^2)\mathrm{d}m=\frac{1}{2}(x^2+y^2)\mathrm{d}m+\int z^2\mathrm{d}m \tag{8.7.256}$$

The first integral is in fact the moment of inertia of the cylinder relatively to the axis G_z and we know it's equal to:

$$J_{G_z}=J_z=M\frac{R^2}{2} \tag{8.7.257}$$

The second integral is easily calculated by cutting the cylinder into slices of thickness $\mathrm{d}z$ perpendicular to the axis G_z. The mass of the elementary slice is $\mathrm{d}m=\pi r^2\rho\mathrm{d}z$ thus:

$$\int z^2\mathrm{d}m=2\int_0^{h/2}\pi r^2\rho z^2\mathrm{d}z=2\pi r^2\rho\frac{h^3}{24}=M\frac{h^2}{12} \qquad (8.7.258)$$

The moment of inertia of a cylinder relative to an axis perpendicular to its axis of revolution is thus written:

$$J_{G_y}=J_y=J_{G_x}=J_x=M\left(\frac{R^2}{4}+\frac{h^2}{12}\right) \qquad (8.7.259)$$

In many high-school problems $R\ll h$ then we can find the latter relation under the form (named a "slender rod"):

$$J_{G_y}=J_{G_x}\cong M\frac{h^2}{12} \qquad (8.7.260)$$

Now let us found the moment of inertia of a cylinder rotation around an axis perpendicular to its rotation axis and at a distance h of one of it ends. To calculate it, we consider:

- The cylinder is cut into a infinitely many pieces of infinitesimally thin slices
- Each of these slices have a mass of $\mathrm{d}m$ and length of $\mathrm{d}x$
- A variable to sum. E.g. in this problem, we are summing from left of the axis to right of axis. The variable is x.

Now, we show our formula for the calculation for moment of inertia first:

$$\mathrm{d}J=x^2\mathrm{d}m \qquad (8.7.261)$$

Recall that we are using x to sum. Hence, we have to force a $\mathrm{d}x$ into the equation for moment of inertia. Now, lets find an expression for $\mathrm{d}m$. Since the rod is uniform, the mass varies linearly with distance such that:

$$\mathrm{d}m=\frac{M}{L}\mathrm{d}x \qquad (8.7.262)$$

Using the relation for $\mathrm{d}m$, we substitute it into the first relation. Hence, we have:

$$\mathrm{d}J=x^2\mathrm{d}m=\frac{M}{L}x^2\mathrm{d}x \qquad (8.7.263)$$

Now we know obviously that:

$$J=\int\mathrm{d}J \qquad (8.7.264)$$

Substituting $\mathrm{d}J$ (with the appropriate limits):

$$J_h=\frac{M}{L}\int\limits_{-h}^{L-h}x^2\mathrm{d}x \qquad (8.7.265)$$

where the lower limit is $-h$ because the left side of the cylinder is $-h$ units away from the axis of rotation (we take right as positive). This part is in fact the tricky part...

Solving the integration, we have the moment of inertia for a uniform rigid cylinder for any perpendicular rotation axis:

$$J_h=\frac{1}{3}M(L^2-3Lh+3h^2) \tag{8.7.266}$$

Now in the special case where $h=0$ (used in many high-school to study a falling chimney) or very small in comparison to L we found the famous relation that can been found in many textbooks (again under the name "slender rod"):

$$J_0=\frac{1}{3}mL^2 \tag{8.7.267}$$

If the rotation axis is through the center of mass of the rod (remember rod is uniform, hence $h=L/2$) we fall back on:

$$J_{h/2}=\frac{1}{12}mL^2 \tag{8.7.268}$$

Now let's also calculate the moment of inertia of an empty tube or cylinder of non-zero thickness (always provided in formula summary textbooks).

The moment of inertia of a tube with respect to its axis of revolution is a classical notion of the moment of inertia of a cylinder. Let us therefore consider a tube of outer radius r_e and inner radius r_i. As (see section Classical Mechanics page 3306):

$$\sum_{i=1}^{n} J_i=J \tag{8.7.269}$$

Therefore, the moment of inertia of a tube can be considered as the moment of inertia of a cylinder of radius equal to the outer radius of the tube, minus the moment of inertia of a cylinder of radius equal to the inner radius of the tube. Therefore:

$$\begin{aligned}J_{\text{tube}}&=J_{r_e}-J_{r_i}=\frac{M_e r_e^2}{2}-\frac{M_i r_i^2}{2}=\frac{1}{2}(\rho\pi r_e^2 h r_e^2-\rho\pi r_i^2 h r_i^2)=\frac{\rho\pi h}{2}(r_e^4-r_i^4)\\&=\frac{\rho\pi h}{2}(r_e^2-r_i^2)(r_e^2+r_i^2)=\frac{\rho\pi h(r_e^2-r_i^2)}{2}(r_e^2+r_i^2)=\frac{M}{2}(r_e^2+r_i^2)\end{aligned} \tag{8.7.270}$$

and if $\bar{r}=r_e^2\cong r_i^2$, then we get the classical relation available in many physics textbooks:

$$J_{\text{tube}}=\frac{M2\bar{r}^2}{2}=M\bar{r}^2 \tag{8.7.271}$$

8.7.2.2.2 Cone

Definition (#8.7.392): A "cone" is a three-dimensional geometric shape that tapers smoothly from a flat base (frequently, though not necessarily, circular) to a point named the "apex" or "vertex".

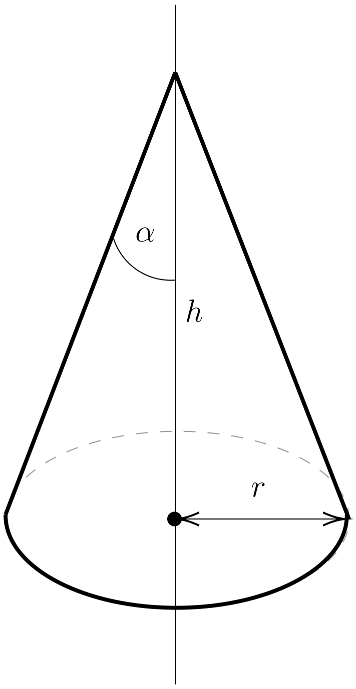


Figure 8.279: **Cone**

The line passing through the points $(r,0)$ (end of the base of the cone/center of the disc) and $(0,h)$ (apex of the cone) is given obviously by:

$$y=ax+b=\frac{-h}{r}x+1h \tag{8.7.272}$$

Indeed, when $x=0$, we have $y=h$ and when $x=r$ we have $y=0$.

The rotation of this line relative to the y-axis gives the volume of the cone:

$$V=\pi\int_a^b x^2\mathrm{d}y=\pi\int_0^h r^2\left(1-\frac{y}{h}\right)^2\mathrm{d}y=\pi r^2\frac{1}{3}\left[\left(1-\frac{y}{h}\right)\right]_0^h(-h)=\frac{-\pi r^2 h}{3}(0-1)=\frac{\pi r^2 h}{3} \tag{8.7.273}$$

Finally:

$$\boxed{V=\frac{\pi r^2 h}{3}} \tag{8.7.274}$$

To calculate the lateral surface of a cone, we will parametrized the straight line that go from the summit of the cone (0.0) to (r,h) so this is a different parametrization than for the volume (this gives the possibility to simplify some calculations). Then we have:

$$f(x)=\frac{r}{h}x \tag{8.7.275}$$

and therefore:

$$\begin{aligned}S_l&=2\pi\int\limits_0^h|f(x)|\sqrt{1+(f'(x))^2}\mathrm{d}x=2\pi\int\limits_0^h\left|\frac{r}{h}x\right|\sqrt{1+\frac{r^2}{h^2}}\mathrm{d}x=2\pi\frac{r}{h}\sqrt{1+\frac{r^2}{h^2}}\int\limits_0^h x\mathrm{d}x\\&=2\pi\frac{r}{h}\sqrt{1+\frac{r^2}{h^2}}\frac{1}{2}x^2\bigg|_0^h=\pi\frac{r}{h}\sqrt{1+\frac{r^2}{h^2}}h^2=\pi rh\sqrt{1+\frac{r^2}{h^2}}=\pi r\sqrt{h^2+r^2}\\&=\pi r^2\sqrt{1+\frac{h^2}{r^2}}\end{aligned}\tag{8.7.276}$$

Therefore, the total surface of the cone (base + side surface) is:

$$S=S_b+S_l=\pi r^2+\pi r^2\sqrt{1+\frac{h^2}{r^2}}=\pi r^2\left(1+\sqrt{1+\frac{h^2}{r^2}}\right)\tag{8.7.277}$$

Finally:

$$\boxed{S=\pi r^2\left(1+\sqrt{1+\frac{h^2}{r^2}}\right)}\tag{8.7.278}$$

Let us now calculate the moment of inertia of a cone with respect to its axis of revolution:

For these calculations we will use the moment of inertia of the cylinder $J_{z,\text{cyl}}$ and consider the cone as a stack of infinitesimal cylinders.

Therefore:

$$\begin{aligned}J_z&=\int\mathrm{d}J_{z,\text{cyl}}=\int\frac{r^2}{2}\mathrm{d}m=\int\frac{r^2}{2}(\rho\pi r^2\mathrm{d}h)=\frac{\pi\rho}{2}\int r^2\mathrm{d}h=\frac{\pi\rho}{2}\frac{H}{R}\int\limits_0^R r^4\mathrm{d}r=\frac{\pi\rho HR^5}{10R}\\&=\left(\rho\frac{\pi R^2H}{3}\right)\frac{3R^2}{10}=\frac{3}{10}MR^2\end{aligned}\tag{8.7.279}$$

8.7.2.2.3 Sphere

Definition (#8.7.393): A "sphere" is a perfectly round geometrical object in three-dimensional space that is the surface of a completely round ball. Like a circle, which geometrically is a two-dimensional object, a sphere is defined mathematically as the set of points that are all at the same distance r (radius) from a given point, but in three-dimensional space. The longest straight line through the ball, connecting two points of the sphere, passes through the center and its length is thus twice the radius (as for the circle); it is the diameter $\varnothing$ of the sphere.

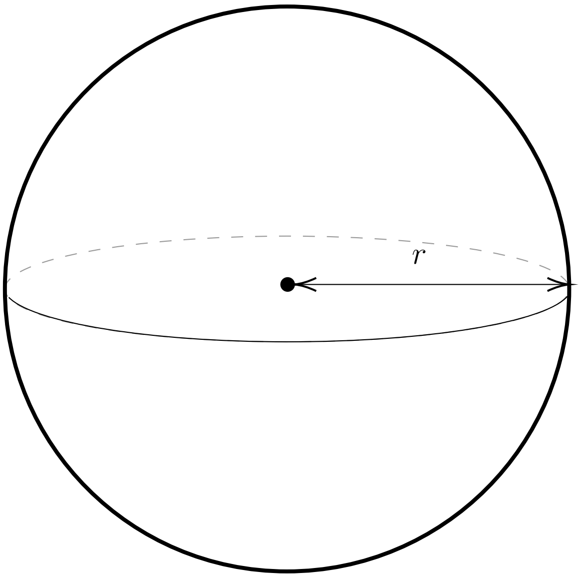

Figure 8.280: **Example of a Sphere**

As the figure above is quite academic, here is a more friendly one if it can help:

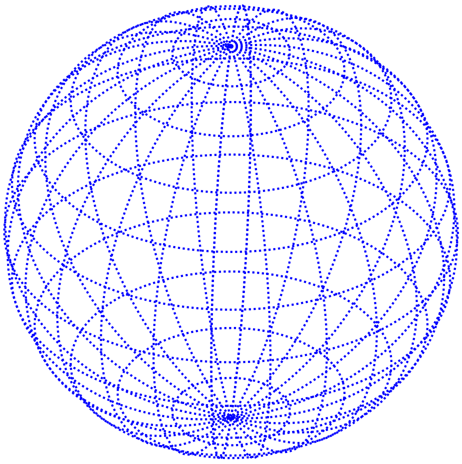

Figure 8.281: **Sphere grid (author: Jeff Hein)**

Obviously we can see a sphere of radius R, as a surface formed by rotating a semicircle around its major axis. The function describing a semicircle being (see section Analytical Geometry page 2768):

$$y=f(x)=\sqrt{R^2+x^2} \qquad (8.7.280)$$

The sphere can be dissected as a sum of disk of thickness Δx. The half-discs being perpendicular to the x-axis and of width Δx at the position x_k (see figure below).

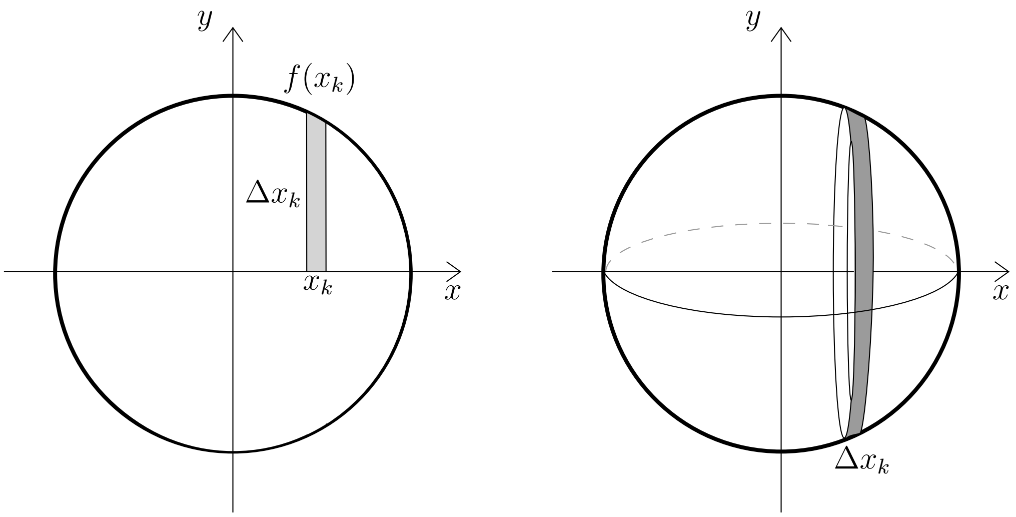

Figure 8.282: **Calculation of the volume of a sphere by a stack of discs**

Then we have:

$$x_k = k\Delta x \tag{8.7.281}$$

The volume of a disk (cylinder) being given by (passing to the limit):

$$\mathrm{d}V_k = \pi r_k^2 \mathrm{d}x \tag{8.7.282}$$

and the radius r_k being given by the function:

$$r_k = f(x_k) = \sqrt{R^2 - x_k^2} \tag{8.7.283}$$

then we have:

$$\mathrm{d}V_k = \pi \left(\sqrt{R^2 - x_k^2}\right)^2 \mathrm{d}x = \pi(R^2 - x_k^2)\mathrm{d}x \tag{8.7.284}$$

By integrating between $x = [-R, R]$, we then have:

$$V = \int\limits_{-R}^{R} \pi(R^2 - r_k^2)\mathrm{d}x = \pi \int\limits_{-R}^{R} \mathrm{d}x = \pi \left(R^2 x - \frac{x^3}{3}\right)\Bigg|_{-R}^{R} \tag{8.7.285}$$

We can also make the terminals as $x = [0, R]$ it gives the same to a factor 2:

$$V = 2\pi \left(R^2 x - \frac{x^3}{3}\right)\Bigg|_{0}^{R} = 2\pi \left(R^3 - \frac{R^3}{3}\right) = 2\pi \frac{3R^3 - R^3}{3} = 2\pi \frac{2R^3}{3} = \frac{4}{3}\pi R^3 \tag{8.7.286}$$

Finally:

$$\boxed{V = \frac{4}{3}\pi R^3} \tag{8.7.287}$$

The expression of the surface being given by differentiation with respect to the element generating the surface, we get (it's a bit limit to say this...):

$$\boxed{S = 4\pi R^2} \tag{8.7.288}$$

There is another way, more rigorous, to approach these both calculations (especially the last one...). Indeed, in the section of Differential and Integral Calculus we have introduced the concept of Jacobian that allows changing the coordinate system based on integration variables we are working on (for a detailed definition the reader should refer to section Differential and Integral Calculus page 1524):

$$\iiint\limits_D f(x,y)\mathrm{d}x\mathrm{d}y=\iiint\limits_D F(u,v,w)|\det(J)|\mathrm{d}u\mathrm{d}v\mathrm{d}w \tag{8.7.289}$$

and we have proved (always in the section of Differential and Integral Calculus page 1528) that the Jacobian in spherical coordinates was:

$$|\det(J)|=r^2\sin(\theta) \tag{8.7.290}$$

So just as $\mathrm{d}x\mathrm{d}y\mathrm{d}z$ is a differential element of volume, we can convert this element into spherical coordinates and make verbatim appear a differential element of volume of the sphere of radius r. We then have just to integrate correctly for the size of the whole sphere.

Therefore we have:

$$\begin{aligned}V&=\iiint\limits_D r^2\sin(\theta)\mathrm{d}r\mathrm{d}\phi\mathrm{d}\theta=\int\limits_0^R r^2\mathrm{d}r\int\limits_0^\pi\sin(\theta)\mathrm{d}\theta\int\limits_0^{2\pi}\mathrm{d}\pi=\left.\frac{r^3}{3}\right|_0^R\cdot\left.(-\cos(\theta))\right|_0^\pi\left.\phi\right|_0^{2\pi}\\&=\frac{R^3}{3}(-\cos(\pi)-(-\cos(0)))2\pi=\frac{2}{3}\pi R^3(-(-1)-(-1))=\frac{4}{3}\pi R^3\end{aligned} \tag{8.7.291}$$

and for the surface (for which the radius is constant):

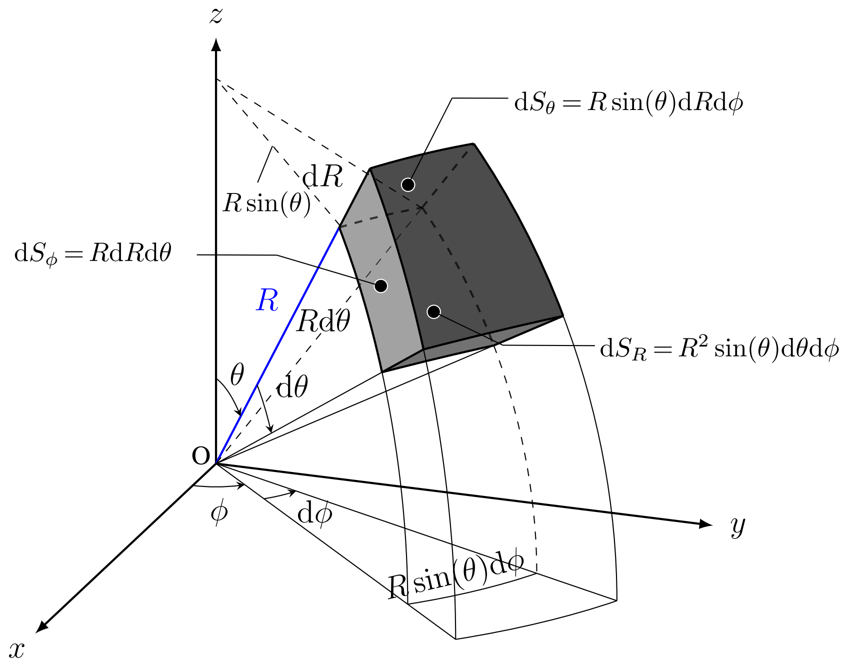
$$\begin{aligned}S&=R^2\iint\sin(\theta)\mathrm{d}\phi\mathrm{d}\theta=R^2\int_0^{2\pi}\sin(\theta)\mathrm{d}\theta\int_0^{2\pi}\mathrm{d}\phi=R^2\left.(-\cos(\theta))\right|_0^\pi\left.\phi\right|_0^{2\pi}\\&=R^2(-\cos(\pi)-(-\cos(0)))2\pi=2\pi R^2(-(-1)-(-1))=4\pi R^2\end{aligned} \tag{8.7.292}$$

If necessary, we can find the element of surface geometrically rather than through the Jacobian because the latter is not very educational in small classes...

Then, remembering that in the section of Trigonometry (see page 2542), we proved that the length of an element circular arc is given by:

$$\mathrm{d}L=R\mathrm{d}\alpha \tag{8.7.293}$$

So, it becomes quite easy to complete the following figure:



z
$\mathrm{d}S_{\theta} = R\sin(\theta)\mathrm{d}R\mathrm{d}\phi$
$\mathrm{d}R$
$R\sin(\theta)$
$\mathrm{d}S_{\phi} = R\mathrm{d}R\mathrm{d}\theta$
R
$R\mathrm{d}\theta$
$\mathrm{d}S_R = R^2\sin(\theta)\mathrm{d}\theta\mathrm{d}\phi$
θ
$\mathrm{d}\theta$
O
ϕ
$\mathrm{d}\phi$
y
$R\sin(\theta)\mathrm{d}\phi$
x

Figure 8.283: **Representation of a surface element in spherical coordinates**

and then we see immediately that (most important surface element for us in this textbook so far for the sections treating of Physics and Engineering!):

$$\mathrm{d}S = R^2\sin(\theta)\mathrm{d}\theta\mathrm{d}\phi \tag{8.7.294}$$

what is obviously more funny...

Let us now calculate the moment of inertia of a homogeneous solid ball of mass M and density ρ. For this, the ball having a maximal symmetry, it is more convenient to first calculate the polar moment of inertia (see section Classical Mechanics page 3306), and then determine the axial moment of inertia using the first result:

$$J_0 = \int r^2\mathrm{d}m = \int r^2\rho\mathrm{d}V = \int r^2\rho(4\pi r^2\mathrm{d}r) = 4\pi\rho\int_0^R r^4\mathrm{d}r = 4\pi\rho\frac{1}{5}R^5 = \frac{4}{3}\pi\rho\frac{3}{5}R^3R^2 = \frac{3}{5}MR^2 \tag{8.7.295}$$

where we used the fact that:

$$\rho = \frac{M}{\dfrac{4}{3}\pi R^3} \tag{8.7.296}$$

As J_x, J_y, J_z are equal by the symmetry of the ball, it comes:

$$J_0 = \frac{1}{2}(3J_x) \Rightarrow J_x = J_y = J_z = \frac{2}{3}J_0 = \frac{2}{5}MR^2 \tag{8.7.297}$$

We give also another derivation if the reader don't like the previous one. For that purpose remember that:

$$J = \sum_i m_i r^2 = \int_{\text{body}} r^2\mathrm{d}m \tag{8.7.298}$$

For a body of uniform composition $\mathrm{d}m = \rho \mathrm{d}V$, where ρ is the density and $\mathrm{d}V$ is the change in volume. For a sphere we have just seen that $\mathrm{d}V = 4\pi/3r^2\mathrm{d}r$. Substitution gives:

$$J = \int_{\text{body}} r^2 \mathrm{d}m = \int_{\text{body}} r^2 \rho \mathrm{d}V = \int_{\text{body}} r^2 \rho \frac{4}{3}\pi r^2 \mathrm{d}r \qquad (8.7.299)$$

So:

$$J = \frac{4\pi\rho}{3}\int\limits_{-R}^{+R} r^4 \mathrm{d}r = \frac{4\pi\rho}{3}\frac{r^5}{5}\bigg|_{-R}^{+R} = \frac{4\pi\rho}{3}\frac{2R^5}{5} \qquad (8.7.300)$$

The mass of the object is given by $M = 4\pi\rho/3R^3$. So:

$$J = \frac{2}{5}MR^2 \qquad (8.7.301)$$

8.7.2.2.3.1 Spherical cap surface

In the field of astronomy we need sometimes to compute the surface of a spherical cap of high h! Let us see how to do this based on the following figure:

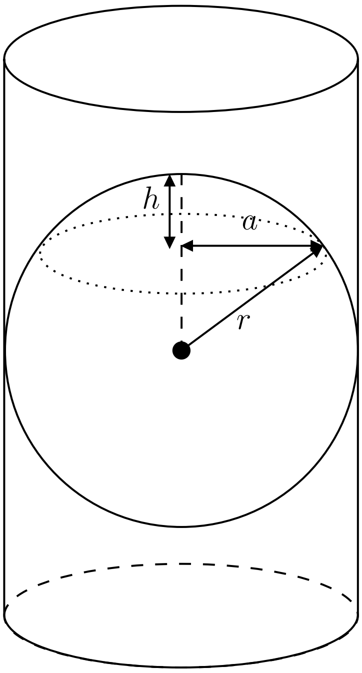


Figure 8.284: **Spherical cap surface derivation trick**

The idea to determiner the spherical cap area we enclose the sphere inside a cylinder of radius r and height $2r$ just touching at a great circle. The projection of the sphere onto the cylinder preserves area.

That is the way it is assumed Archimedes derived that the area of the sphere is same as lateral surface area of the cylinder which is for reminder for our special case:

$$S_{\text{cylinder}} = (2\pi r)(2r) = 4\pi r^2 \qquad (8.7.302)$$

The projection of the cap on the cylinder has area:

$$S_{\text{sph. cap}} = (2\pi r)\cdot h \tag{8.7.303}$$

And since:

$$a^2 = r^2 - (r-h)^2 = 2rh - h^2 \Rightarrow 2rh = h^2 + a^2 \tag{8.7.304}$$

the area of the cap can therefore be written:

$$S_{\text{sph. cap}} = (2\pi r)\cdot h = \pi(2rh) = \pi\left(h^2 + a^2\right) \tag{8.7.305}$$

In astronomy we have most of the time as starting information not h (nor a) but the percentage length $\%\ell$ of a half great circle (that has obviously for length ${}^1\!/\!{}_2\mathcal{C} = 2\pi r/2 = \pi r$) whose corresponding projection in the sphere axis is $h < r$ (in the case the projection is greater than r we will sum et subtract multiple sphere caps).

The trick to get the area of spherical cap in percentage $\%\ell$ of a half great circle is to think in its equivalent in angle π (half of the corresponding angle of the entire great circle). Therefore:

$$h = r - r\cos\left(\frac{\%\ell\pi}{2}\right) = r\left[1-\cos\left(\frac{\%\ell\pi}{2}\right)\right] \tag{8.7.306}$$

and identically:

$$a = r\sin\left(\frac{\%\ell\pi}{2}\right) \tag{8.7.307}$$

Hence the corresponding spherical cap area as used in astronomy:

$$\begin{aligned} S_{\text{sph. cap}} &= \pi\left(h^2+a^2\right) = \pi\left\{r^2\left[1-\cos\left(\frac{\%\ell\pi}{2}\right)\right]^2 + r^2\sin^2\left(\frac{\%\ell\pi}{2}\right)\right\} \\ &= 2r^2 - 2r^2\cos^2\left(\frac{\%\ell\pi}{2}\right) = 2r^2\sin^2\left(\frac{\%\ell\pi}{2}\right) \end{aligned} \tag{8.7.308}$$

8.7.2.2.3.2 Sphere packing

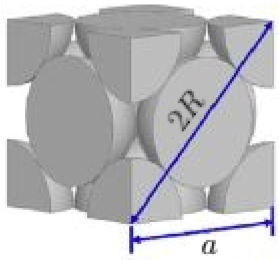
In geometry, a sphere packing is an arrangement of non-overlapping spheres within a containing space. The spheres considered are usually all of identical size, and the space is usually three-dimensional Euclidean space. A typical sphere packing problem is to find an arrangement in which the spheres fill as much of the space as possible. The proportion of space filled by the spheres is named the "density of the arrangement".

Many problems in the chemical and physical sciences can be related to sphere packing problems where more than one size of sphere is available. Here there is a choice between separating the spheres into regions of close-packed equal spheres, or combining the multiple sizes of spheres into a compound or interstitial packing (when many sizes of spheres - or a distribution - are available, the problem quickly becomes intractable).

For the very special case of equal spheres in three dimensions, the densest packing uses approximately 74% of the volume.

Proof 8.27.3. Let us see for the two famous cases:

- FCC (face cubic center) structure:



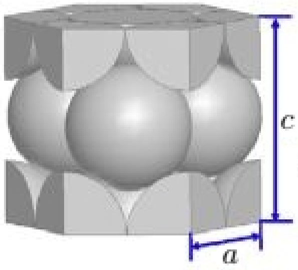
First we see obviously as the diagonal of the cube is equal to four times a sphere radius ($4R$) that using the Pythagoras theorem:

$$(4R)^2=a^2+a^2\Rightarrow 4R=\sqrt{2}a\Rightarrow R=\frac{\sqrt{2}}{4}a \tag{8.7.309}$$

Therefore, denoting V_s the volume of a sphere and V_e the volume of the cube:

$$\text{Packing factor}=\frac{V_s}{V_e}=\frac{4\cdot\frac{4\pi}{3}R^3}{a^3}=\frac{4\cdot\frac{4\pi}{3}\cdot\left(\frac{\sqrt{2}}{4}a\right)^3}{a^3}=\frac{\sqrt{2}\pi}{6}=74.05\% \tag{8.7.310}$$

- HCP (hexagonal close packed):



First we see obviously that:

$$c=\sqrt{\frac{8}{3}}a \qquad \text{and} \qquad R=\frac{a}{2} \tag{8.7.311}$$

Therefore:

$$\text{Packing factor}=\frac{V_s}{V_3}=\frac{6\cdot\frac{4\pi}{3}R^3}{6\cdot\frac{1}{2}\cdot\frac{\sqrt{3}}{2}a^2\cdot c}=\frac{6\cdot\frac{4\pi}{3}\cdot\left(\frac{a}{2}\right)^2}{6\cdot\frac{1}{2}\cdot\frac{\sqrt{3}}{2}a^2\cdot\frac{\sqrt{8}}{3}a}=\frac{\sqrt{2}\pi}{6}=74.05\% \tag{8.7.312}$$

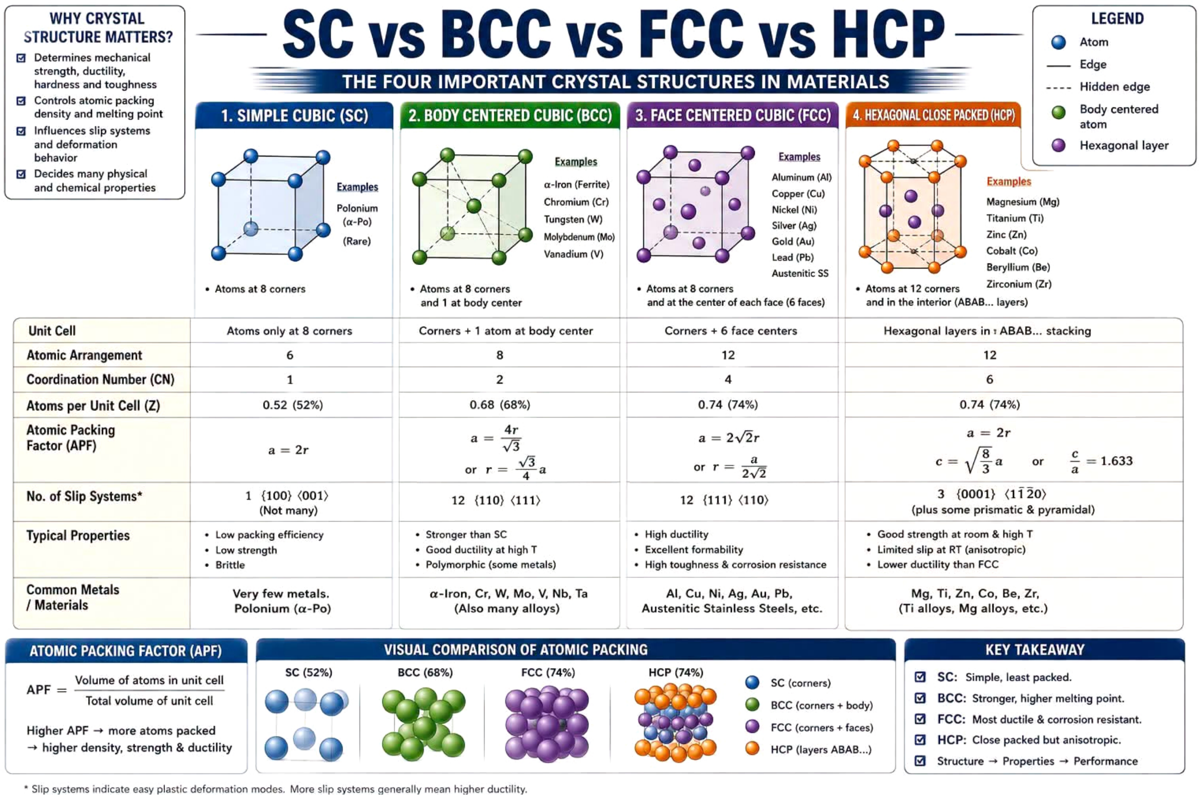
■ Q.E.D.

Carl Friedrich Gauss proved in 11831 (holocene calendar) in a non-trivial and non-formal way that these packings have the highest density amongst all possible lattice packings (we won't provide the proof here as it is quite non-elegant in our personal and subjective point of view).

In 11611 (holocene calendar) Johannes Kepler conjectured that this is the maximum possible density amongst both regular and irregular arrangements—this became known as the "Kepler conjecture". In 11998 (holocene calendar), Thomas Callister Hales, following the approach suggested by László Fejes Tóth in 11953 (holocene calendar), announced a proof of the Kepler conjecture (for a good presentation of the proof see [222]). Hales' proof is a proof by exhaustion involving checking of many individual cases using complex computer calculations. Referees said that they were "99% certain" of the correctness of Hales' proof. On 10 August 12014 (holocene calendar) Hales announced the completion of a formal proof using automated proof checking, removing any doubt.

Remark

Some other lattice packings are often found in physical systems. These include the cubic lattice with a density of $\frac{\pi}{6}\cong 0.5236$, the hexagonal lattice with a density of $\frac{\pi}{3\sqrt{3}}\cong 0.6046$ and the tetrahedral lattice with a density of $\frac{\pi\sqrt{3}}{16}\cong 0.3401$, and loosest possible at a density of 0.0555.



WHY CRYSTAL STRUCTURE MATTERS?

- ☑ Determines mechanical strength, ductility, hardness and toughness
- ☑ Controls atomic packing density and melting point
- ☑ Influences slip systems and deformation behavior
- ☑ Decides many physical and chemical properties

SC vs BCC vs FCC vs HCP

THE FOUR IMPORTANT CRYSTAL STRUCTURES IN MATERIALS

LEGEND

- ● Atom
- — Edge
- ---- Hidden edge
- ● Body centered atom
- ● Hexagonal layer

1. SIMPLE CUBIC (SC)

Examples: Polonium (α-Po) (Rare)

- Atoms at 8 corners

2. BODY CENTERED CUBIC (BCC)

Examples: α-Iron (Ferrite), Chromium (Cr), Tungsten (W), Molybdenum (Mo), Vanadium (V)

- Atoms at 8 corners and 1 at body center

3. FACE CENTERED CUBIC (FCC)

Examples: Aluminum (Al), Copper (Cu), Nickel (Ni), Silver (Ag), Gold (Au), Lead (Pb), Austenitic SS

- Atoms at 8 corners and at the center of each face (6 faces)

4. HEXAGONAL CLOSE PACKED (HCP)

Examples: Magnesium (Mg), Titanium (Ti), Zinc (Zn), Cobalt (Co), Beryllium (Be), Zirconium (Zr)

- Atoms at 12 corners and in the interior (ABAB... layers)

	1. SIMPLE CUBIC (SC)	2. BODY CENTERED CUBIC (BCC)	3. FACE CENTERED CUBIC (FCC)	4. HEXAGONAL CLOSE PACKED (HCP)
Unit Cell	Atoms only at 8 corners	Corners + 1 atom at body center	Corners + 6 face centers	Hexagonal layers in ı ABAB... stacking
Atomic Arrangement	6	8	12	12
Coordination Number (CN)	1	2	4	6
Atoms per Unit Cell (Z)	0.52 (52%)	0.68 (68%)	0.74 (74%)	0.74 (74%)
Atomic Packing Factor (APF)	$a = 2r$	$a = \frac{4r}{\sqrt{3}}$ or $r = \frac{\sqrt{3}}{4}a$	$a = 2\sqrt{2}r$ or $r = \frac{a}{2\sqrt{2}}$	$a = 2r$ $c = \sqrt{\frac{8}{3}}a$ or $\frac{c}{a} = 1.633$
No. of Slip Systems*	1 {100} ⟨001⟩ (Not many)	12 {110} ⟨111⟩	12 {111} ⟨110⟩	3 {0001} $\langle 1\bar{1}\bar{2}0\rangle$ (plus some prismatic & pyramidal)
Typical Properties	• Low packing efficiency • Low strength • Brittle	• Stronger than SC • Good ductility at high T • Polymorphic (some metals)	• High ductility • Excellent formability • High toughness & corrosion resistance	• Good strength at room & high T • Limited slip at RT (anisotropic) • Lower ductility than FCC
Common Metals / Materials	Very few metals. Polonium (α-Po)	α-Iron, Cr, W, Mo, V, Nb, Ta (Also many alloys)	Al, Cu, Ni, Ag, Au, Pb, Austenitic Stainless Steels, etc.	Mg, Ti, Zn, Co, Be, Zr, (Ti alloys, Mg alloys, etc.)

ATOMIC PACKING FACTOR (APF)

$$\text{APF} = \frac{\text{Volume of atoms in unit cell}}{\text{Total volume of unit cell}}$$

Higher APF → more atoms packed → higher density, strength & ductility

VISUAL COMPARISON OF ATOMIC PACKING

- ● SC (corners)
- ● BCC (corners + body)
- ● FCC (corners + faces)
- ● HCP (layers ABAB...)

KEY TAKEAWAY

- ☑ **SC:** Simple, least packed.
- ☑ **BCC:** Stronger, higher melting point.
- ☑ **FCC:** Most ductile & corrosion resistant.
- ☑ **HCP:** Close packed but anisotropic.
- ☑ Structure → Properties → Performance

* Slip systems indicate easy plastic deformation modes. More slip systems generally mean higher ductility.

Finally notice that many people like to compute how many times the Earth can be contained inside Jupiter or inside the Sun. Dividing the volume for example of the Sun (actually a G2V-type star, aka yellow dwarf) by that of Earth obviously gives a value ($\sim 1,300,000$) that assumes that the Earth can be cut into infinitesimal volumes. But if we consider that we can't cut the Earth into infinitesimal volumes (sphere packing problem), then the number is approximately $\sim 932,884$. Value to compare with $1,300,000\cdot 74.05\% = 962,624$.

8.7.2.2.4 Torus

Definition (#8.7.394): A "torus" is the surface generated by rotating a circle c of "minor radius" r around a straight line at a distance R, named "major radius" from its center located in its plane, but not passing through its center. In other words, it is a surface of revolution generated by revolving a circle in three-dimensional space about an axis coplanar with the circle and that does not touch the circle:

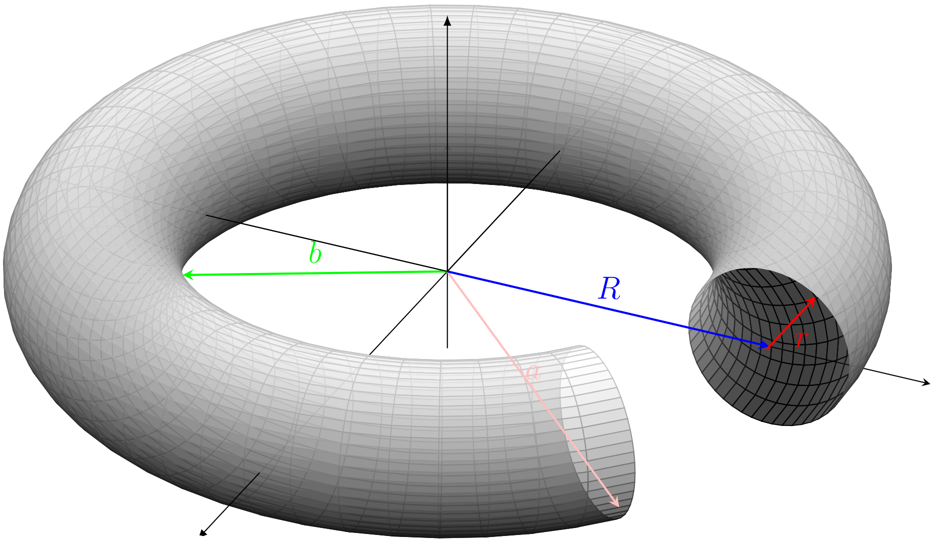


Figure 8.285: Torus

We see obviously in the figure above that: $a-b=2R$.

To calculate the volume we could obviously use Pappus's centroid theorem as proved in the section of Classical Mechanic. But the latter method is not very elegant and quite "physics" oriented. We will look therefore for a more pure mathematical approach.

Given the equation of a semicircle of center $(0,c)$ (see section Analytical Geometry page 2785):

$$x^2+(y-c)^2=r^2 \tag{8.7.313}$$

In order to write y as a function of x, let us isolate y in this equation:

$$x^2+(y-c)^2=r^2 \Leftrightarrow (y-c)^2=r^2-x^2 \Leftrightarrow y-c=\pm\sqrt{r^2-x^2} \Leftrightarrow y=c\pm\sqrt{r^2-x^2} \tag{8.7.314}$$

The circle is then made of the graphs of the following functions:

- Top semicircle:

$$f_1: x \mapsto c+\sqrt{r^2-x^2} \tag{8.7.315}$$

- Bottom semicircle:

$$f_2: x \mapsto c-\sqrt{r^2-x^2} \tag{8.7.316}$$

Let us denote now by usage with the study of the torus $R := c$.

The requested volume is the difference between the volumes generated by the rotation of the surfaces (surfaces defined by the area between the function of the circle in question and the axis of abscissa $x = r, x = -r$) in the space around the x-axis.

By applying the integration relation of solids of revolution we get:

$$\begin{aligned}
V=V_1-V_2&=\pi\int\limits_{-r}^{r}(R+\sqrt{r^2-x^2})^2\mathrm{d}x-\pi\int\limits_{-r}^{r}(R-\sqrt{r^2-x^2})^2\mathrm{d}x\\
&=\pi\int\limits_{-r}^{r}\left[(R+\sqrt{r^2-x^2})^2-(R-\sqrt{r^2-x^2})^2\right]\mathrm{d}x\\
&=\pi\int\limits_{-r}^{r}\left[(R^2+2R\sqrt{r^2-x^2}+r^2-x^2)-(R^2-2R\sqrt{r^2-x^2}+r^2-x^2\right]\mathrm{d}x\\
&=\pi\int\limits_{-r}^{r}(R^2+2R\sqrt{r^2-x^2}+r^2-x^2-R^2+2R\sqrt{r^2-x^2}-r^2+x^2)\mathrm{d}x\\
&=\pi\int\limits_{-r}^{r}4R\sqrt{r^2-x^2}\mathrm{d}x=4\pi c\int\limits_{-r}^{r}\sqrt{r^2-x^2}\mathrm{d}x
\end{aligned}\tag{8.7.317}$$

Let us calculate the latter integral by the classical substitution $x = r\sin(t)$ thus:

$$\mathrm{d}x=(r\sin(t))'\mathrm{d}t=r\cos(t)\mathrm{d}t\tag{8.7.318}$$

if $x = -r$:

$$-r=r\sin(t)\Rightarrow\sin(t)=-1\Rightarrow -t=\frac{\pi}{2}\tag{8.7.319}$$

if $x = r$:

$$r=r\sin(t)\Rightarrow\sin(t)=1\Rightarrow t=\frac{\pi}{2}\tag{8.7.320}$$

Therefore:

$$\begin{aligned}
V&=4\pi R\int\limits_{-\pi/2}^{\pi/2}\sqrt{r^2-r^2\sin^2(t)}r\cos(t)\mathrm{d}t=4\pi R\int\limits_{-\pi/2}^{\pi/2}\sqrt{r^2(1-\sin^2(t)}r\cos(t)\mathrm{d}t\\
&=4\pi R\int\limits_{-\pi/2}^{\pi/2}r\sqrt{\cos^2(t)}r\cos(t)\mathrm{d}t=4\pi Rr^2\int\limits_{-\pi/2}^{\pi/2}|\cos(t)|\cos(t)\mathrm{d}t=4\pi Rr^2\int\limits_{-\pi/2}^{\pi/2}\cos^2(t)\mathrm{d}t
\end{aligned}\tag{8.7.321}$$

Let us linearise that expression again using the trigonometric identities proved in the section

Trigonometry (Carnot's formula at page 2520):

$$\begin{aligned}V&=4\pi Rr^2\int\limits_{-\pi/2}^{\pi/2}\frac{1}{2}(1+\cos(2t))\mathrm{d}t=2\pi Rr^2\left(\int\limits_{-\pi/2}^{\pi/2}\mathrm{d}t+\int\limits_{-\pi/2}^{\pi/2}\cos(2t)\mathrm{d}t\right)\\&=2\pi Rr^2\left(t\Big|_{-\pi/2}^{\pi/2}+\frac{1}{2}\int\limits_{-\pi/2}^{\pi/2}2\cos(2t)\mathrm{d}t\right)=2\pi Rr^2\left(\frac{\pi}{2}-\left(-\frac{\pi}{2}\right)+\frac{1}{2}\left[\sin(2t)\right]\Big|_{-\pi/2}^{\pi/2}\right)\\&=2\pi Rr^2\left(\pi+\frac{1}{2}(\sin(\pi)-\sin(-\pi))\right)=2\pi Rr^2\left(\pi+\frac{1}{2}(0-0)\right)=2R\pi^2r^2\end{aligned}\tag{8.7.322}$$

So the volume of a torus of a minor radius r and major radius R is given by:

$$\boxed{V=2R\pi^2r^2}\tag{8.7.323}$$

and the surface (by derivation of the generating surface element... but there are many other elementary way to get this result):

$$\boxed{S=\frac{\mathrm{d}V}{\mathrm{d}r}=4Rr\pi^2}\tag{8.7.324}$$

The moment of inertia of the torus in relation to its axis of revolution is calculated as follows:

First we start using the torus volume by change the notations a little bit:

$$V=2\pi^2a^2b\tag{8.7.325}$$

The volumetric density of the torus is given by (weight to volume):

$$\rho=\frac{M}{V}=\frac{\mathrm{d}m}{\mathrm{d}V}\Leftrightarrow\mathrm{d}m=\frac{M}{2\pi^2a^2b}\mathrm{d}V\tag{8.7.326}$$

In cylindrical coordinates, we know that we have:

$$\mathrm{d}V=r\mathrm{d}r\mathrm{d}\theta\mathrm{d}z\tag{8.7.327}$$

Therefore:

$$\mathrm{d}m=\frac{M}{2\pi^2a^2b}\mathrm{d}V=\frac{M}{2\pi^2a^2b}r\mathrm{d}r\mathrm{d}\theta\mathrm{d}z\tag{8.7.328}$$

The moment of inertia is given by:

$$\begin{aligned}J&=\int r^2\mathrm{d}m=2\left(\frac{M}{2\pi^2a^2b}\int\limits_0^{2\pi}\mathrm{d}\theta\int\limits_{b-a}^{b+a}r^2\mathrm{d}r\int\limits_0^{\sqrt{a^2-(r-b)^2}}\mathrm{d}z\right)=\frac{M}{\pi^2a^2b}\int_0^{2\pi}\mathrm{d}\theta\int\limits_{b-a}^{b+a}r^3\mathrm{d}r\sqrt{a^2-(r-b)^2}\\&=\frac{M}{\pi^2a^2b}\int_0^{2\pi}\mathrm{d}\theta\int\limits_{b-a}^{b+a}r^3\sqrt{a^2-(r-b)^2}\mathrm{d}r=\frac{2\pi M}{\pi^2a^2b}\int\limits_{b-a}^{b+a}\sqrt{a^2-(r-b)^2}\mathrm{d}r\\&=\frac{2M}{\pi a^2b}\int\limits_{b-a}^{b+a}\sqrt{a^2-(r-b)^2}\mathrm{d}r\end{aligned}\tag{8.7.329}$$

Let us put $s=r-b$, then:

1. The limits of integration then become $-a$, $+a$, as we bring all integration points at the origin by putting $s=r-b$.
2. Trivially, since $r=s+b$ so we have $\mathrm{d}s=\mathrm{d}r$.

Which gives:

$$\begin{aligned}J_z&=\frac{2M}{\pi a^2 b}\int\limits_{b-a}^{b+a} r^2\sqrt{a^2-(r-b)^2}\mathrm{d}r=\frac{2M}{\pi a^2 b}\int\limits_{-a}^{a}(s+b)^3\sqrt{a^2-s^2}\mathrm{d}s\\&=\frac{2M}{\pi a^2 b}\int_{-a}^{+a}(s^3+3s^2b+3sb^2+b^3)\sqrt{a^2-s^2}\mathrm{d}s\end{aligned}\tag{8.7.330}$$

As we have proved in the section of Differential and Integral Calculus that the integral with two symmetrical terminals of an odd function (product of an even and odd function) is zero (see page 1516), the integrals of:

$$s^3\sqrt{a^2-s^2}\mathrm{d}s\qquad 3sb^2\sqrt{a^2-s^2}\mathrm{d}s\tag{8.7.331}$$

are equal to zero.

Then we have to calculate:

$$J_z=\frac{2M}{\pi a^2 b}\int\limits_{-a}^{+a}(3s^2b+b^3)\sqrt{a^2-s^2}\mathrm{d}s\tag{8.7.332}$$

Now let us put $s=a\sin(t)$ and therefore $\mathrm{d}s=a\cos(t)\mathrm{d}t$. Therefore it comes:

$$J_z=\frac{2M}{\pi a^2 b}\int\limits_{-\pi/2}^{+\pi/2}(3a^2\sin^2(t)b+b^3)\sqrt{a^2-a^2\sin^2(t)}a\cos(t)\mathrm{d}t\tag{8.7.333}$$

But as:

$$\cos^2(t)+\sin^2(t)=1\Rightarrow a^2\cos^2(t)+a^2\sin^2(t)=a^2\Rightarrow\sqrt{a^2-a^2\sin^2(t)}=|a\cos(t)|\tag{8.7.334}$$

Therefore:

$$\begin{aligned}J_z&=\frac{2M}{\pi a^2}\int\limits_{-\pi/2}^{+\pi/2}(3a^2\sin^2(t)+b^2)|a\cos(t)|a\cos(t)\mathrm{d}t=\frac{2M}{\pi a^2}\int\limits_{-\pi/2}^{+\pi/2}(3a^2\sin^2(t)+b^2)a^2\cos^2(t)\mathrm{d}t\\&=\frac{2M}{\pi}\int\limits_{-\pi/2}^{+\pi/2}(3a^2\sin^2(t)+b^2)\cos^2(t)\mathrm{d}t=\frac{2M}{\pi}\int\limits_{-\pi/2}^{+\pi/2}(3a^2\sin^2(t)\cos^2(t)+b^2\cos^2(t))\mathrm{d}t\\&=\frac{2M}{\pi}\int\limits_{-\pi/2}^{+\pi/2}(3a^2(1-\cos^2(t))\cos^2(t)+b^2\cos^2(t))\mathrm{d}t\\&=\frac{2M}{\pi}\int\limits_{-\pi/2}^{+\pi/2}(3a^2\cos^2(t)-3a^2\cos^4(t)+b^2\cos^2(t))\mathrm{d}t\end{aligned}\tag{8.7.335}$$

Therefore (see section Differential and Integral Calculus page 1534):

$$\int\limits_{-\pi/2}^{+\pi/2} 3a^2\cos^2(t)\mathrm{d}t = 3a^2\int\limits_{-\pi/2}^{+\pi/2}\cos^2(t)\mathrm{d}t = \frac{1}{2}3a^2(\cos(t)\sin(t)+t)\Big|_{-\pi/2}^{+\pi/2} = 3a^2\frac{\pi}{2}$$
$$\int\limits_{-\pi/2}^{+\pi/2} b^2\cos^2(t)\mathrm{d}t = b^2\int\limits_{-\pi/2}^{+\pi/2}\cos^2(t)\mathrm{d}t = \frac{b^2}{2}(\cos(t)\sin(t)+t)\Big|_{-\pi/2}^{+\pi/2} = b^2\frac{\pi}{2}$$
$$\int\limits_{-\pi/2}^{+\pi/2} 3a^2\cos^4(t)\mathrm{d}t = 3a^2\int\limits_{-\pi/2}^{+\pi/2}\cos^4(t)\mathrm{d}t = \left(\frac{1}{4}\cos^3(t)\sin(t)+\frac{3}{8}\cos(t)\sin(t)+\frac{3}{8}t\right)\Big|_{-\pi/2}^{+\pi/2} = 3a^2\frac{3\pi}{8} \tag{8.7.336}$$

So finally:

$$J_z = \frac{2M}{\pi}\left(-3a^2\frac{3\pi}{8}+b^2\frac{\pi}{2}+3a^2\frac{\pi}{2}\right) = M\left(\frac{3}{4}a^2+b^2\right) \tag{8.7.337}$$

8.7.2.2.5 Ellipsoid (spheroid)

Definitions (#8.7.395):

D1. An "ellipsoid" is a surface of the second degree of a three dimensional Euclidean space. It is therefore part of quadrics (see section Analytical Geometry page 2765) given by the equation:

$$\boxed{\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1} \tag{8.7.338}$$

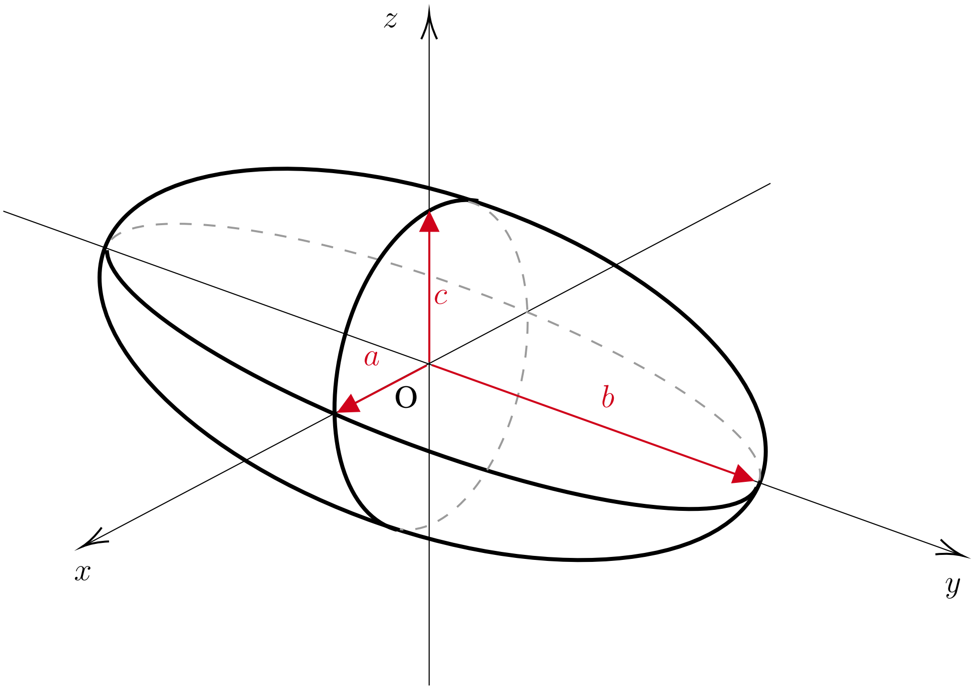

Figure 8.286: **Ellipsoid**

D2. A "spheroid", or "ellipsoid of revolution, is a quadric surface obtained by rotating an ellipse about one of its principal axes; in other words, an ellipsoid with two equal semi-diameters.

The equation of a spheroid with z as the symmetry axis is given by setting $a=b$:

$$\boxed{\frac{x^2+y^2}{a^2}+\frac{z^2}{c^2}=1} \tag{8.7.339}$$

If the ellipse is rotated about its major axis, the result is a "prolate (elongated) spheroid", like an American football or rugby ball. If the ellipse is rotated about its minor axis, the result is an "oblate (flattened) spheroid", like a lentil:

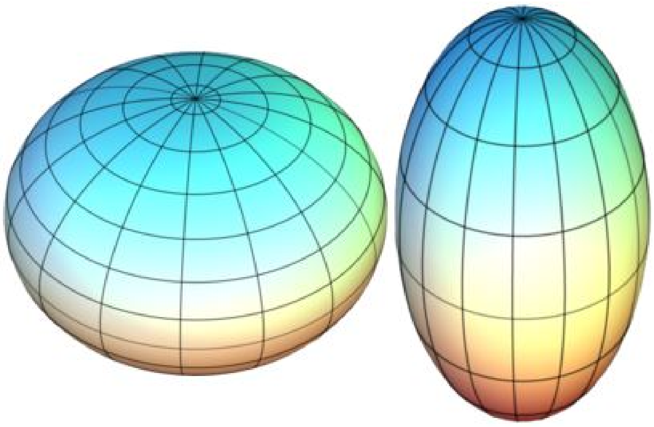

Figure 8.287: **Oblate spheroid on the left, prolate one on the right (source: Wikipedia)**

To calculate the volume delimited by an ellipsoid, we take the equation that we have determined during our study of conicals:

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1 \tag{8.7.340}$$

The section by a plane parallel to the plane YZ and lying at a distance x of the latter, gives the ellipse:

$$\frac{y^2}{b^2}+\frac{z^2}{c^2}=1-\frac{x^2}{a^2} \tag{8.7.341}$$

or:

$$\frac{y^2}{b^2\left(1-\dfrac{x^2}{a^2}\right)}+\frac{z^2}{c^2\left(1-\dfrac{x^2}{a^2}\right)}=\frac{y^2}{\left(b\sqrt{1-\dfrac{x^2}{a^2}}\right)}+\frac{z^2}{\left(c\sqrt{1-\dfrac{x^2}{a^2}}\right)}=1 \tag{8.7.342}$$

with for semi-axes:

$$b_1=b\sqrt{1-\frac{x^2}{a^2}} \qquad c_1=c\sqrt{1-\frac{x^2}{a^2}} \tag{8.7.343}$$

But as we proved it earlier, the surface of an ellipse is equal to $\pi b_1 c_2$. Therefore:

$$\boxed{S=\pi bc\left(1-\frac{x^2}{a^2}\right)} \tag{8.7.344}$$

The volume of the ellipsoid is therefore equal to:

$$\begin{aligned}V&=\pi bc\int\limits_{-a}^{+a}\left(1-\frac{x^2}{a^2}\right)\mathrm{d}x=\pi bc\left(x-\frac{x^3}{3a^2}\right)\Bigg|_{-a}^{+a}=\pi bc\left[\left(a-\frac{a^3}{3a^2}\right)-\left((-a)-\frac{(-a)^3}{3a^2}\right)\right]\\&=\pi bc\left(2a-2\frac{a^3}{3a^2}\right)=\pi bc\left(2a-\frac{2}{3}a\right)\end{aligned} \tag{8.7.345}$$

Therefore:

$$\boxed{V=\frac{4}{3}\pi abc} \tag{8.7.346}$$

If $a=b=c=R$ we fall back on the volume of a sphere:

$$V=\frac{4}{3}\pi R^3 \tag{8.7.347}$$

Let us now calculate the surface and volume of an oblate spheroid. Remember that its Cartesian equation is:

$$\frac{x^2+y^2}{a^2}+\frac{z^2}{c^2}=1 \tag{8.7.348}$$

The ellipticity of an oblate spheroid is defined by:

$$e=\sqrt{1-\frac{c^2}{a^2}} \tag{8.7.349}$$

The surface area of an oblate spheroid can be computed as a surface of revolution about the z-axis:

$$S=2\pi\int r(z)\sqrt{1+(r'(z))^2}\mathrm{d}z \tag{8.7.350}$$

with radius function of z given by:

$$r(z)=a\sqrt{1-\left(\frac{z}{c}\right)^2} \tag{8.7.351}$$

Therefore:

$$(r'(z))^2=\left(-\frac{az}{c^2\sqrt{1-\frac{z^2}{c^2}}}\right)^2=\frac{a^2z^z}{c^4\left(1-\left(\frac{z}{c}\right)^2\right)} \tag{8.7.352}$$

Therefore:

$$\begin{aligned}S&=2\pi\int a\sqrt{1-\left(\frac{z}{c}\right)^2}\sqrt{1+\frac{a^2z^z}{c^4\left(1-\left(\frac{z}{c}\right)^2\right)}}\mathrm{d}z=2\pi a\int\sqrt{\left(1-\left(\frac{z}{c}\right)^2\right)+\frac{a^2z^z}{c^4}}\mathrm{d}z\\&=2\pi a\int\sqrt{1-\left(\frac{z}{c}\right)^2+\frac{a^2z^z}{c^4}}\mathrm{d}z=2\pi a\int\sqrt{1-\frac{a^2z^2-z^2c^4}{c^2}}\mathrm{d}z=2\pi a\int\sqrt{1-\frac{(a-c)(a+c)}{c^2}z^2}\mathrm{d}z\end{aligned} \tag{8.7.353}$$

If we put:

$$\alpha^{-1}:=\frac{(a-c)(a+c)}{c^2} \tag{8.7.354}$$

We can then write the integral as following:

$$F(z)=\int\sqrt{\alpha-z^2}\mathrm{d}z \tag{8.7.355}$$

And as we have seen in the section of Differential and Integral Calculus the usual primitives (see page 1534) and the following identity $-\arcsin(\alpha)=\arcsin(-\alpha)$ in the section of Trigonometry (see 2519):

$$\begin{aligned}F(z)&=\left(\frac{\alpha^2}{2}\arcsin\left(\frac{z}{\alpha}\right)+\frac{z}{2}\sqrt{\alpha^2-z^2}\right)\Bigg|_{-c}^{+c}\\&=\left(\frac{\alpha^2}{2}\arcsin\left(\frac{-c}{\alpha}\right)+\frac{-c}{2}\sqrt{\alpha^2-(-c)^2}\right)-\left(\frac{\alpha^2}{2}\arcsin\left(\frac{c}{\alpha}\right)+\frac{c}{2}\sqrt{\alpha^2-(c)^2}\right)\\&=-c\sqrt{\alpha^2-c^2}+\alpha^2\arcsin\left(\frac{c}{\alpha}\right)\end{aligned} \tag{8.7.356}$$

Therefore:

$$S=2\pi a\left[-c\sqrt{\alpha^2-c^2}+\alpha^2\arcsin\left(\frac{c}{\alpha}\right)\right]=2\pi a\left[-c\sqrt{\left(\frac{c^2}{a^2-c^2}\right)^2-c^2}+\alpha^2\arcsin\left(\frac{c}{\alpha}\right)\right] \tag{8.7.357}$$

The calculation of the moment of inertia of an ellipsoid is very important in astrophysics since a large number of stars or planets in rotation on themselves by their deformation at the equator because of the centrifugal (fictional) force (see section Classical Mechanics page 3388) are being distorted in a first approximation in this volume.

For an ellipsoid, define C as being the moment of inertia along the c-axis, A is the moment of inertia along the a-axis, and B the moment of inertia along the b-axis.

To begin, let us consider the moment of inertia along the c-axis that we will assimilate to the z-axis. Thus, in Cartesian coordinates, we have:

$$J_z=C=\int r^2\mathrm{d}m=\int\rho r^2\mathrm{d}V=\rho\int r^2\mathrm{d}v=\rho\int(x^2+y^2)\mathrm{d}x\mathrm{d}y\mathrm{d}z \tag{8.7.358}$$

By making the following substitution, we implicitly do that the previous integral is a normalization of an ellipsoid:

$$x'=\frac{x}{a},y'=\frac{y}{b},z'=\frac{z}{c} \tag{8.7.359}$$

what gives us for our integral (so we transform the volume V of the ellipsoid in the volume V' of a sphere):

$$C=\rho\int\left((ax')^2+(by')2\right)abc \tag{8.7.360}$$

We can now move from Cartesian coordinates to spherical coordinates (see section Vector Calculus page 1849) without forgetting to use the Jacobian (see section Differential and Integral Calculus page 1524) that we had proved as being in spherical coordinates given by:

$$|\det(J)|=r^2\sin(\theta) \tag{8.7.361}$$

Therefore (we use again the common primitives proved in the section of Differential and Integral

Calculus):

$$\begin{aligned}
C &= abc\rho \int\limits_0^1 \int\limits_0^{2\pi} \int\limits_0^{\pi} (a^2 r^2 \cos^2(\phi)\sin^2(\theta) + b^2 r^2 \sin^2(\phi)\sin^2(\theta) r^2 \sin(\theta)\mathrm{d}\theta\mathrm{d}\phi\mathrm{d}r \\
&= abc\rho \int\limits_0^1 \int\limits_0^{2\pi} \int\limits_0^{\pi} (a^2\cos^2(\phi) + b^2\sin^2(\phi))r^4\sin^3(\theta)\mathrm{d}\theta\mathrm{d}\phi\mathrm{d}r \\
&= abc\rho \int\limits_0^1 \int\limits_0^{2\pi} \int\limits_0^{\pi} (a^2\cos^2(\phi) + b^2\sin^2(\phi))r^2 \left(-\frac{1}{3}\cos(\theta)\sin^2(\theta) - \frac{2}{3}\cos(\theta)\right)\Bigg|_0^{\pi} \mathrm{d}\phi\mathrm{d}r \\
&= \frac{4}{3}abc\rho \int\limits_0^1 \int\limits_0^{2\pi} (a^2\cos^2(\phi) + b^2\sin^2(\phi) r^2 \mathrm{d}\phi\mathrm{d}r \\
&= \frac{4}{3}abc\rho \int\limits_0^1 \left(a^2\pi + b^2\pi\right) r^4 \mathrm{d}r = \frac{4}{3}abc\pi\rho(a^2+b^2) \int\limits_0^1 r^4\mathrm{d}r \\
&= \frac{4}{15}abc\pi\rho(a^2+b^2)r^5\Bigg|_0^1 = \frac{4}{15}\pi\rho abc(a^2+b^2)
\end{aligned} \tag{8.7.362}$$

By injecting for the ellipsoid:

$$\rho = \frac{M}{V} = \frac{M}{\dfrac{4}{3}\pi abc} \tag{8.7.363}$$

Then we get:

$$C = \frac{1}{5}M(a^2+b^2) \tag{8.7.364}$$

and by symmetry, we get the following obvious results:

$$\begin{aligned}
A &= J_x = \frac{1}{5}M(b^2+c^2) \\
B &= J_y = \frac{1}{5}M(a^2+c^2) \\
C &= J_z = \frac{1}{5}M(a^2+b^2)
\end{aligned} \tag{8.7.365}$$

The inertia matrix (see section Classical Mechanics page 3310) is therefore:

$$(J_0)_{(\vec{i},\vec{j},\vec{k})} = \begin{pmatrix} \frac{1}{5}M(b^2+c^2) & 0 & 0 \\ 0 & \frac{1}{5}M(a^2+c^2) & 0 \\ 0 & 0 & \frac{1}{5}M(a^2+b^2) \end{pmatrix} \tag{8.7.366}$$

8.7.2.2.6 Paraboloid

Definition (#8.7.396): A "paraboloid" is as we already know a quadric surface of special kind. There are two kinds of paraboloids: elliptic and hyperbolic.

The "elliptic paraboloid" is shaped like an oval cup and can have a maximum or minimum point. In a suitable coordinate system with three axes x, y, and z, it can be represented by the equation:

$$\frac{z}{c}=\frac{x^2}{a^2}+\frac{y^2}{b^2} \tag{8.7.367}$$

where a and b are constants that dictate the level of curvature in the xz and yz planes respectively. This is an elliptic paraboloid which opens upward for $c>0$ and downward for $c<0$.

The latter relations is more commonly written as:

$$z=c^2\frac{x^2}{a^2}+c^2\frac{y^2}{b^2}=a'x^2+b'y^2 \tag{8.7.368}$$

The "hyperbolic paraboloid" - not to be confused with a hyperboloid (see section Analytical Geometry page 2841) - is a doubly ruled surface shaped like a saddle. In a suitable coordinate system, a hyperbolic paraboloid can be represented by the equation:

$$\frac{z}{c}=\frac{y^2}{b^2}-\frac{x^2}{a^2} \tag{8.7.369}$$

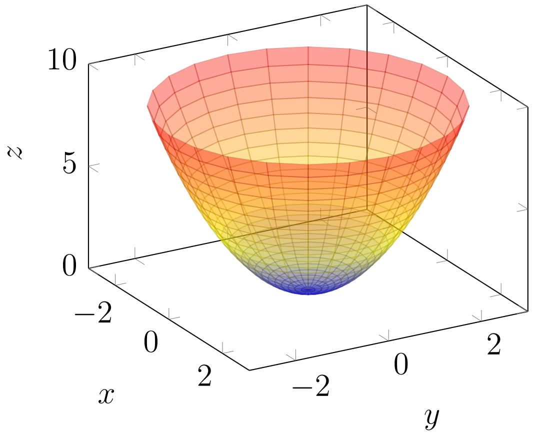

Figure 8.288: Paraboloid of revolution

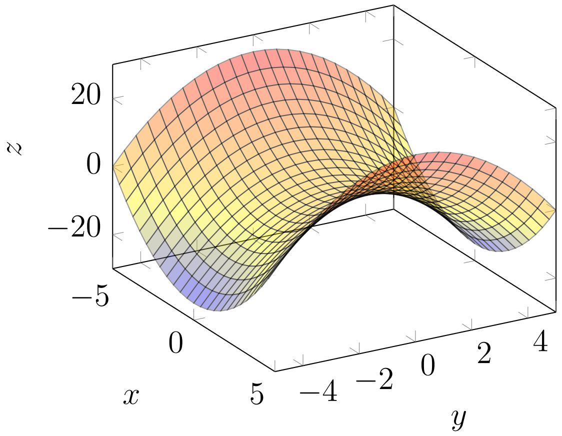

Figure 8.289: Hyperbolic paraboloid

We will only calculate the volume of the paraboloid of revolution as it is the only result that we need in the other chapters of this textbook at this date. For this purpose let us consider the following figure:

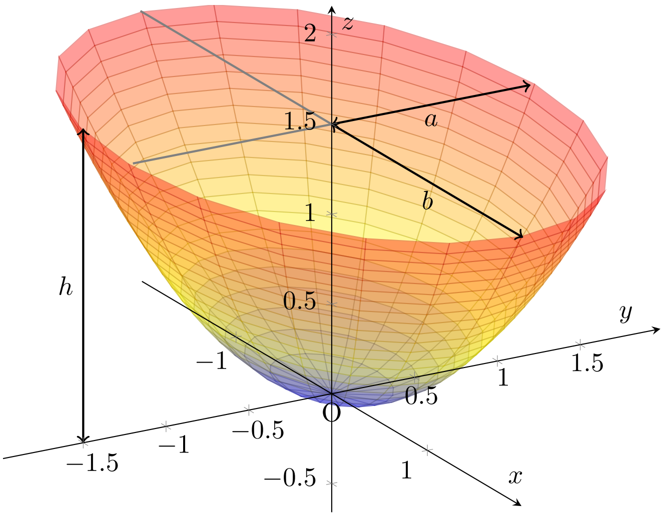

Figure 8.290: **Elliptic paraboloid**

Given by:

$$z=\frac{x^2}{a^2}+\frac{y^2}{b^2} \tag{8.7.370}$$

Looking at the figure above we see that the parameters a and b depends on the value of z. So as the surface of an ellipse is given by $\mathrm{d}S=\pi ab$, we have for every height of the paraboloid:

$$S(z)=\pi a(z)b(z) \tag{8.7.371}$$

So in the xz plane as we have $y=0$ then:

$$z=\frac{x^2}{a^2}\Leftrightarrow a(z)=|x|\sqrt{\frac{1}{z}} \tag{8.7.372}$$

and also same for the plane yz:

$$z=\frac{y^2}{b^2}\Leftrightarrow b(z)=|y|\sqrt{\frac{1}{z}} \tag{8.7.373}$$

And we know that when $z=h$ we must have $a(h)=a$, and when $z=0$ we must have $a(h)=0$ (same with b). So we have to write:

$$a(z)=a\sqrt{\frac{z}{h}} \qquad b(z)=b\sqrt{\frac{z}{h}} \tag{8.7.374}$$

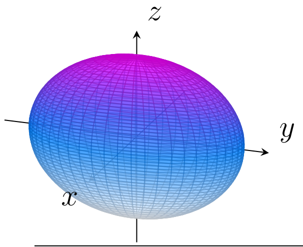
Therefore:

$$V_h=\int\limits_0^h S(z)\mathrm{d}z=\int\limits_0^h \pi a(z)b(z)\mathrm{d}z=\pi\int\limits_0^h a\sqrt{\frac{z}{h}}b\sqrt{\frac{z}{h}}\mathrm{d}z=\pi ab\frac{1}{h}\int\limits_0^h |z|\mathrm{d}z=\pi ab\frac{1}{h}\frac{1}{2}h^2 \tag{8.7.375}$$

Hence:

$$\boxed{V_h=\frac{1}{2}\pi abh} \tag{8.7.376}$$

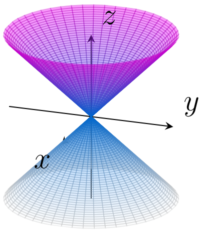
Quadric Surfaces at a Glance



Ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

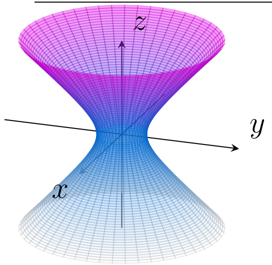
All traces are ellipses. If $a = b = c$, the ellipsoid is a sphere.



Cone

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = \frac{z^2}{c^2}$$

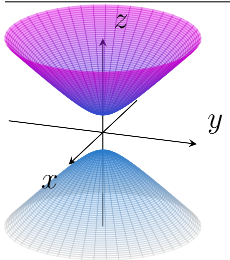
Horizontal traces are ellipses. Vertical traces are hyperbolas (or a pair of lines). In general, the surface opens along the axis corresponding to the squared term that is on a side of the equation by itself.



Hyperboloid of One Sheet

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1$$

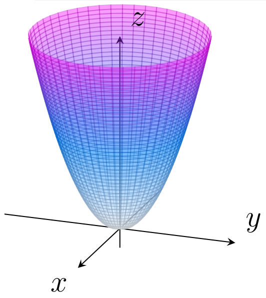
Horizontal traces are ellipses. Vertical traces are hyperbolas (or pairs of lines). In general, the surface opens along the axis corresponding to the variable whose coefficient is negative.



Hyperboloid of Two Sheets

$$\frac{z^2}{c^2} - \frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$

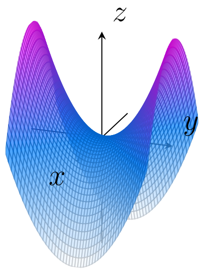
Horizontal traces are ellipses (or a single point or nothing). Vertical traces are hyperbolas. The surface opens along the axis corresponding to the variable whose coefficient is positive.



Elliptic Paraboloid

$$\frac{z}{c} = \frac{x^2}{a^2} + \frac{y^2}{b^2}$$

Horizontal traces are ellipses (or a point or nothing). Vertical traces are parabolas. The paraboloid opens upward when $c > 0$ and downward when $c < 0$. In general, the surface opens along the axis corresponding to the variable raised to the first power.



Hyperbolic Paraboloid

$$\frac{z}{c} = \frac{x^2}{a^2} - \frac{y^2}{b^2}$$

Horizontal traces are hyperbolas (or a pair of lines). Vertical traces are parabolas. In general, the parabolas open along the axis corresponding to the variable raised to the first power.

Figure 8.291: Quadric surfaces at a glance (author: Dave Richeson)

8.7.2.2.7 Gabriel's horn

"Gabriel's horn" (also named "Torricelli's trumpet") is a geometric figure which has infinite surface area but finite volume. The name refers to the Abrahamic tradition identifying the Archangel Gabriel as the angel who blows the horn to announce Judgement Day, associating the divine, or infinite, with the finite. The properties of this figure were first studied by Italian physicist and mathematician Evangelista Torricelli in the 117th century (holocene calendar).

Gabriel's horn is formed by taking the graph of:

$$f(x) \mapsto \frac{1}{x} \tag{8.7.377}$$

with the domain $x \geq 1$ and rotating it in three dimensions about the x-axis. With Maple™ 4.00b we can plot it using (notice that is has the same shape as a gravitational potential or electric potential):

```
>plot3d(1/x, theta=0..2*Pi, x = 1..20, coords=cylindrical
```

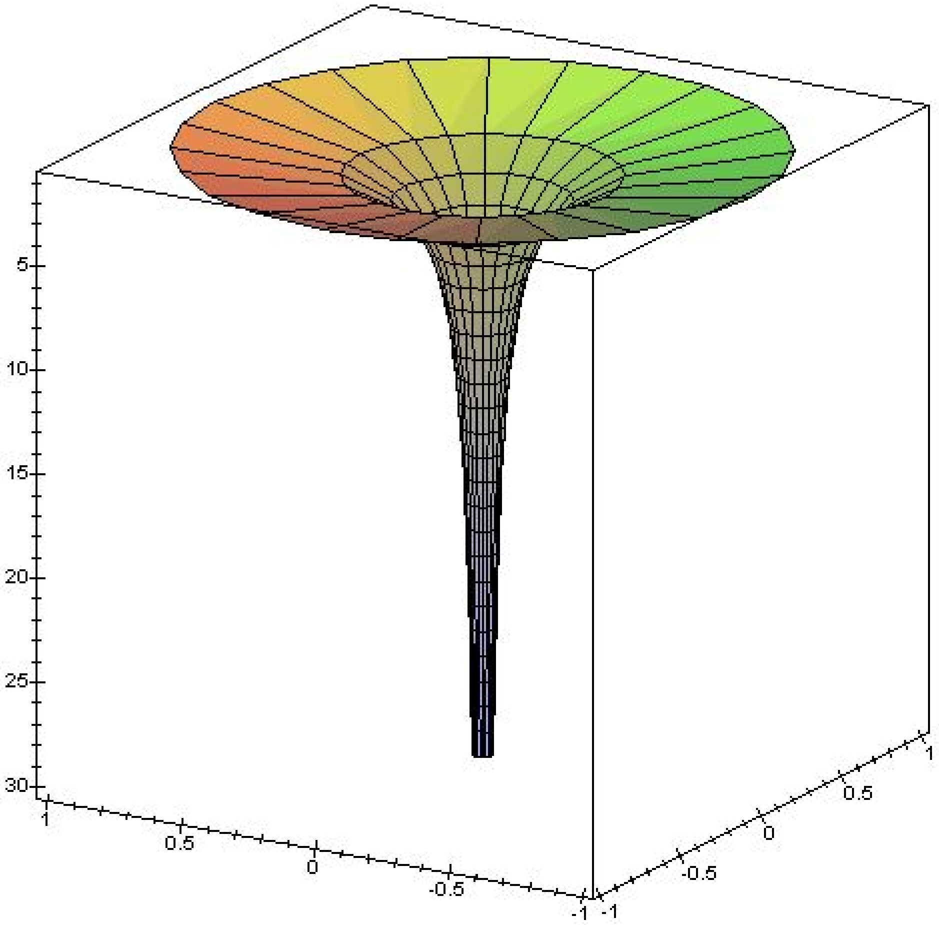


Figure 8.292: **Gabriel's horn with Maple™ 4.00b**

The discovery was made using Cavalieri's principle before the invention of calculus, but today calculus can be used to calculate the volume and surface area of the horn between $x = 1$ and $x = a$, where $a > 1$. Using integration, it is possible to find the volume V (using the method of discs again for the volume) and the surface area S:

$$\begin{gathered}
V=\pi\int\limits_1^a (f(x))^2\,\mathrm{d}x=\pi\int\limits_1^a\left(\frac{1}{x}\right)^2\mathrm{d}x=\pi\left(1-\frac{1}{a}\right)\\
S=2\pi\int\limits_a^b f(x)\sqrt{1+(f'(x))^2}\mathrm{d}x=2\pi\int\limits_1^a\frac{1}{x}\sqrt{1+\left(-\frac{1}{x^2}\right)^2}\mathrm{d}x>2\pi\int\limits_1^a\frac{\mathrm{d}x}{x}=2\pi\ln(a)
\end{gathered}\tag{8.7.378}$$

The parameter a can be as large as required, but it can be seen from the equation that the volume of the part of the horn between $x=1$ and $x=a$ will never exceed π; however, it will get closer and closer to π as a becomes larger. Mathematically, the volume approaches π as a approaches infinity. Using the limit notation of calculus:

$$\lim_{a\rightarrow+\infty}V=\lim_{a\rightarrow+\infty}\pi\left(1-\frac{1}{a}\right)=\pi\cdot\lim_{a\rightarrow+\infty}\left(1-\frac{1}{a}\right)=\pi\tag{8.7.379}$$

The surface area formula above gives a lower bound for the area as 2π times the natural logarithm of a. There is no upper bound for the natural logarithm of a as a approaches infinity. That means, in this case, that the horn has an infinite surface area. That is to say:

$$\lim_{a\rightarrow+\infty}S\geq\lim_{a\rightarrow+\infty}2\pi\ln(a)=+\infty\tag{8.7.380}$$

The apparent paradox formed part of a dispute over the nature of infinity involving many of the key thinkers of the time including Thomas Hobbes, John Wallis and Galileo Galilei.

Remark

Since the horn has finite volume but infinite surface area, there is an apparent paradox that the horn could be filled with a finite quantity of paint, and yet that paint would not be sufficient to coat its inner surface. The "paradox" is resolved by realizing that a finite amount of paint can in fact coat an infinite surface area - it simply needs to get thinner at a fast enough rate.

The converse phenomenon of Gabriel's horn – a surface of revolution that has a finite surface area but an infinite volume – cannot occur (there is a proof but it is not a very aesthetic one so we will not present it here).

8.7.2.2.8 Wine Barrel with Circular Section

Now let us look for fun to a well known volume for winemakers (and not only!):

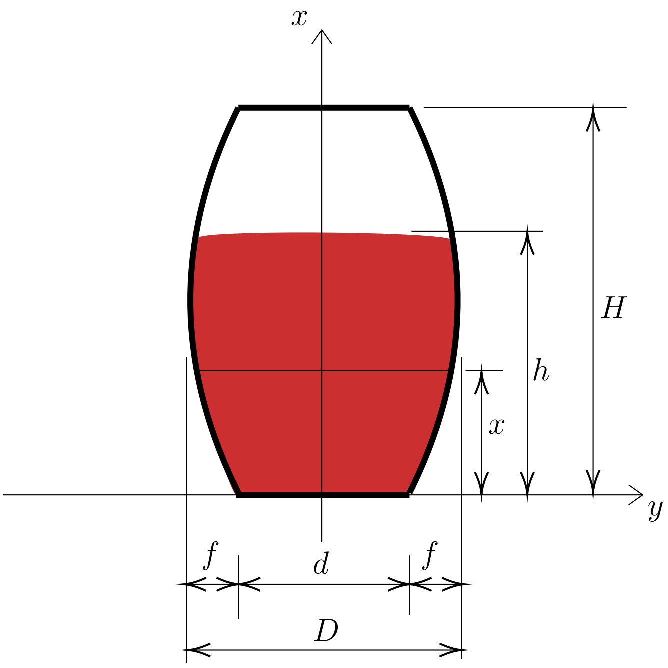

Figure 8.293: **Wine Barrel with circular section**

Let us consider that the lateral curvature of the barrel is a parabola:

$$y=ax^2+bx+c \tag{8.7.381}$$

Let us put:

$$f=\frac{D-d}{2} \quad \text{and} \quad L=\frac{H}{2} \tag{8.7.382}$$

given the way we have put the x,y-axis it is relatively easy to determine the coefficients of the polynomial. The coefficient c is the simplest:

$$c=y(x=0)=\frac{d}{2} \tag{8.7.383}$$

We also have:

$$y'=0=2ax+b\Rightarrow 2a\frac{H}{2}+b=2aL+b=0\Rightarrow a=\frac{-b}{2L} \tag{8.7.384}$$

Also:

$$\begin{gathered}y\left(x=\frac{H}{2}\right)=a\left(x=\frac{H}{2}\right)^2+b\frac{H}{2}+c=-\frac{b}{2L}L^2+bL+\frac{d}{2}=\frac{D}{2}\\ \Rightarrow b\left(-\frac{L}{2}+L\right)=\frac{D-d}{2}\Rightarrow b\frac{L}{2}=f\Rightarrow b=\frac{2f}{L}\end{gathered} \tag{8.7.385}$$

Therefore we have:

$$a=-\frac{f}{L^2} \quad b=\frac{2f}{L} \quad c=\frac{d}{2} \tag{8.7.386}$$

The radius of a horizontal section of ordinate x is $r=y$ and its surface is therefore:

$$S=\pi r^2 \tag{8.7.387}$$

or:

$$S=\pi(ax^2+bx+c)^2 \tag{8.7.388}$$

Let us develop this:

$$\begin{aligned}S&=\pi\left(a^2x^4+b^2x^2+c^2+2ax^2(bx+c)+bxc\right)\\&=\pi\left(a^2x^4+b^2x^2+c^2+2abx^3+2acx^2+2bxc\right)\end{aligned} \tag{8.7.389}$$

The volume of liquid for a height h will then be:

$$\begin{aligned}V&=\int\limits_0^h(a^2x^4+b^2x^2+c^2+2abx^3+2acx^2+2bcx)\mathrm{d}x\\&=\pi\left[a^2\frac{x^5}{5}+b^2\frac{x^3}{3}+c^2x+2ab\frac{x^4}{4}+2ac\frac{x^3}{3}+2bc\frac{x^2}{2}\right]\Bigg|_0^h\\&=\pi\left[a^2\frac{h^5}{5}+2ab\frac{h^4}{4}+b^2\frac{h^3}{3}+2ac\frac{h^3}{3}+2bc\frac{h^2}{2}+c^2h\right]\\&=\pi\left[a^2\frac{h^5}{5}+ab\frac{h^4}{2}+(2ac+b^2)\frac{h^3}{3}+bch^2+c^2h\right]\end{aligned} \tag{8.7.390}$$

To calculate the inner surface of the wine barrel, we consider the outer curve given by a parabolic arc as shown below:

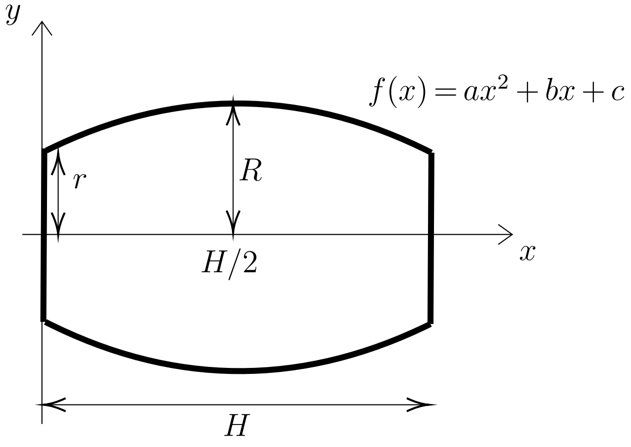

Figure 8.294: **Vertical section of the wine barell**

To calculate the lateral area of the barrel, we must first determine the expression of the above parabola.

Looking at the figure, we get:

$$\begin{aligned}f(0)&=r=c\\f(H)&=r=aH^2+bH+c\\f\left(\frac{H}{2}\right)&=a\frac{H^2}{4}+b\frac{H}{2}+c=R\end{aligned} \tag{8.7.391}$$

which is a system of three equations with the unknowns a, b, c.

After resolution, we get:

$$\begin{aligned} a &= \frac{4(r-R)}{H^2} \\ b &= \frac{4(R-r)}{H} \\ c &= r \end{aligned} \tag{8.7.392}$$

The side surface of the barrel including the surface of the two disks at the ends is then given by:

$$S = 2\pi r^2 + 2\pi \int\limits_0^H |f(x)|\sqrt{1+(f'(x))^2}\mathrm{d}x = 2\pi r^2 + 2\pi \int\limits_0^H (ax^2+bx+c)\sqrt{1+(2ax+b)^2}\mathrm{d}x \tag{8.7.393}$$

By doing the change of variable $u = 2ax+b$ we get:

$$S = 2\pi r^2 + \frac{\pi}{4a^2}\int\limits_b^{2aH+b}(u^2-b^2+4ac)\sqrt{u^2+1}\mathrm{d}u \tag{8.7.394}$$

The latter integral can be calculated using the following relations (the second has been proved in the section of Differential and Integral Calculus the first one need to be detailed when we will have the time...):

$$\begin{aligned} \int u^2\sqrt{u^2+1}\mathrm{d}u &= \frac{1}{4}u\left(u^2+\frac{1}{2}\right)\sqrt{u^2+1}-\frac{1}{8}\text{arcsinh}(u) \\ \int \sqrt{u^2+1}\mathrm{d}u &= \frac{1}{2}u\sqrt{u^2+1}+\frac{1}{2}\text{arcsinh}(u) \end{aligned} \tag{8.7.395}$$

Where for recall (see section Trigonometry page 2532):

$$\text{arcsinh}(z) = \ln(u+\sqrt{u^2+1}) \tag{8.7.396}$$

We will not go further because the resulting formula would be huge and not very interesting in our point of view (but on request we will do it).

Nevertheless, here is a numerical application. Suppose $r = 20$ [cm], $R = 30$ [cm], $H = 60$ [cm].

We calculate:

$$a = -0.0111, b = 0.667, c = 20 \tag{8.7.397}$$

Therefore:

$$S = 2.513\cdot 10^3 + 6.362\cdot 10^3\int\limits_{0.667}^{-0.667}u^2\sqrt{u^2+1}\mathrm{d}u - 8.483\cdot 10^3\int\limits_{0.667}^{-0.667}\sqrt{u^2+1}\mathrm{d}u \tag{8.7.398}$$

The first integral is equal to:

$$\int\limits_{0.667}^{-0.667}u^2\sqrt{u^2+1}\mathrm{d}u = -0.222 \tag{8.7.399}$$

The second integral is equal to:

$$\int\limits_{0.667}^{-0.667}\sqrt{u^2+1}\mathrm{d}u=-1.427 \tag{8.7.400}$$

So finally we get:

$$S\cong 1.321\,[\mathrm{m}^2] \tag{8.7.401}$$

To summarize everything seen so far about surfaces and volumes, let us show all surfaces elements in 2D and also all surfaces elements in 3D and volumes techniques used so far:

8.7.3 Isoperimetric inequality (2D)

The text that follows is almost just a copy/paste of a text written by Jeremy Booher where we added some missing details and cross-references! The reader will see that the method follows a clever process that is very interesting to learn how to make some kind of abstract proofs on geometric objects.

Of all figures in the plane with a given perimeter, which has the greatest area? The Greeks knew the answer to this question, although they could not prove it. Part of the problem was that the notion of perimeter and area are tricky notions, requiring analysis to deal with properly. A rigorous proof had to wait until the 119th century (holocene calendar). There are now many proofs of the isoperimetric inequality. We will focus on the case where the boundary of the figure is a piecewise $\mathcal{C}^1$ curve in order to sweep the analytic issues about area and perimeter under the rug. Remember that being piecewise $\mathcal{C}^1$ means that the closed curve is continuously differentiable except at a finite number of points.

Theorem 8.28. (Isoperimetric Inequality) Let γ be a closed curve in the plane that is piecewise $\mathcal{C}^1$. Let $A=\mathcal{A}(\text{Int}(\gamma))$ be the area enclosed by the curve and $L=\mathcal{L}(\gamma)$ the perimeter. We have:

$$4\pi A \leq L^2 \tag{8.7.402}$$

with equality holding if and only if the curve is a circle (that's what lead us to claim that the circle is for a shape of a given perimeter, the shape having the biggest area). Indeed in the case where the curve is a circle, we have:

$$4\pi(\pi R^2)\leq(2\pi R)^2 \Rightarrow 1=1 \tag{8.7.403}$$

Hence the area is maximized when the shape is a circle (therefore the equality holds!). In other words, the isoperimetric inequality constrains how large the surface can be. You'll note that this inequality is maximized when the bounding perimeter is a circle!

In other words, any 2D (i.e. planer) surface that satisfies:

$$\frac{L^2}{A}=4\pi \tag{8.7.404}$$

maximizes the surface for a given perimeter!

Remark

The boundary curve need not be piecewise $\mathcal{C}^1$: with more analysis, less needs to be assumed about γ. However, this is more than sufficient to encompass common figures likes polygons and circles.

The proof we will introduce below is named the "Hurwitz's proof via Actions". For this to make sense, the curve must be piecewise $\mathcal{C}^1$ as we will assume throughout. Several useful facts are:

- If $\gamma(t)=(x(t),y(t))$ is a curve from $[a,b]\rightarrow\mathbb{R}^2$, its length can be calculated as we know by the relation (see section Differential Geometry 2856):

$$\mathcal{L}(\gamma)=\int_a^b\sqrt{\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2+\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2}\,\mathrm{d}t \tag{8.7.405}$$

- If $\gamma(t)$ is a curve from $[0,\pi]\rightarrow\mathbb{R}^2$ (you can apply the same reasoning with the same result by choosing $[0,2\pi]\rightarrow\mathbb{R}^2$) with the polar coordinates of $\gamma(t)$ given by $r(t)$ and $\theta(t)$, the length of the curve is:

$$\mathcal{L}(\gamma)=\int\limits_0^{\pi}\sqrt{\left(\dfrac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2}\mathrm{d}t \tag{8.7.406}$$

This follows by making the change of variable $x=r\cos(\theta)$ and $y=r\sin(\theta)$ in the previous relation. Indeed, in polar coordinates we define the curve by the equation $r=f(t)$. In order to adapt the arc length formula for a polar curve, we use the equations:

$$x=r\cos(\theta)=f(t)\cos(\theta(t)) \tag{8.7.407}$$

$$y=r\sin(\theta)=f(t)\sin(\theta(t)) \tag{8.7.408}$$

Therefore:

$$\begin{aligned}\dfrac{\mathrm{d}x}{\mathrm{d}t}&=f'(t)\cos(\theta(t))-f(t)\sin(\theta(t))\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\\ \dfrac{\mathrm{d}y}{\mathrm{d}t}&=f'(t)\sin(\theta(t))+f(t)\cos(\theta(t))\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\end{aligned} \tag{8.7.409}$$

Hence:

$$\begin{aligned}L&=\int\limits_a^b\sqrt{\left(\dfrac{\mathrm{d}x}{\mathrm{d}t}\right)^2+\left(\dfrac{\mathrm{d}y}{\mathrm{d}t}\right)^2}\mathrm{d}t\\ &=\int\limits_a^b\sqrt{\left(f'(t)\cos(\theta(t))-f(t)\sin(\theta(t))\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2+\left(f'(t)\sin(\theta(t))+f(t)\cos(\theta(t))\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2}\mathrm{d}t\\ &=\int\limits_a^b\sqrt{(f'(t))^2\left(\cos^2(\theta(t))+\sin^2(\theta(t))\right)+f(t)^2\left(\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2\left(\cos^2(\theta(t))+\sin^2(\theta(t))\right)}\mathrm{d}t\\ &=\int\limits_a^b\sqrt{(f'(t))^2+f(t)^2\left(\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2}\mathrm{d}t=\int\limits_{\alpha}^{\beta}\sqrt{r^2+\left(\dfrac{\mathrm{d}r}{\mathrm{d}\theta}\right)^2}\mathrm{d}t=\int\limits_a^b\sqrt{\left(\dfrac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2}\mathrm{d}t\end{aligned} \tag{8.7.410}$$

- With the notation above, the area inside the curve is given by:

$$\mathcal{A}(\mathrm{Int}(\gamma))=\dfrac{1}{2}\int\limits_0^{\pi}r(t)^2\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\mathrm{d}t \tag{8.7.411}$$

Indeed, similar to Cartesian equations, we can find the exact area of the polar region using an integral. The only exception is that we are using sectors to approximate the area, not rectangles, therefore:

$$A=\dfrac{\theta}{2\pi}\pi r^2 \tag{8.7.412}$$

Therefore:

$$\mathrm{d}A=\frac{\mathrm{d}\theta}{2\pi}\pi r(\theta)^2=\frac{1}{2}r(t)^2\mathrm{d}\theta=\frac{1}{2}r(t)^2\frac{\mathrm{d}\theta}{\mathrm{d}t}\mathrm{d}t \tag{8.7.413}$$

Hence as $\gamma(t)$ is a curve from $[0,\pi]\rightarrow\mathbb{R}^2$, we have:

$$A=\int\limits_0^\pi \frac{1}{2}r(t)^2\frac{\mathrm{d}\theta}{\mathrm{d}t}\mathrm{d}t \tag{8.7.414}$$

- The Cauchy-Schwarz inequality for integrals says that for square integrable functions f and g from $[0,\pi]\rightarrow\mathbb{R}$ we have (see section Functional Analysis 2388):

  $$\left(\int\limits_0^\pi f(t)g(t)\mathrm{d}t\right)^2\leq\int\limits_0^\pi f(t)^2\mathrm{d}t\int\limits_0^\pi g(t)^2\mathrm{d}t \tag{8.7.415}$$

  Equality is achieved if and only if g is a multiple of f.

The concept of action appears in physics and allows a reformulation of classical mechanics in terms of action and Lagrangians. For our purposes, all we need is the following definition of the action of a curve, which should be thought of as a physical property of a particle following that trajectory.

So let us remind that given $\gamma:[a,b]\rightarrow\mathbb{R}^2$ a plane curve. The action of the path γ is defined to be (see section Classical Mechanics page 3364):

$$\mathcal{E}(\gamma):=\frac{1}{2}\int_a^b\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2+\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2\mathrm{d}t=\frac{1}{2}\int_a^b\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2\mathrm{d}t \tag{8.7.416}$$

Unlike the length of the curve, the action of the curve depends on the parametrization of the curve. Therefore, we need to standardize how to parametrize curves.

The "standard parametrization" of a curve γ is the one for which the parameter's interval is $[0,\pi]$.

Since the definitions of action and length are similar, it is no surprise that they are related!

Lemma 8.28.1. Let γ be a curve with standard parametrization. Then:

$$\mathcal{L}(\gamma)^2\leq 2\pi\mathcal{E}(\gamma) \tag{8.7.417}$$

with equality achieved if and only if the parameter is a multiple of arc length along γ.

Proof 8.28.1. By Cauchy-Schwarz:

$$\left(\int_0^\pi f(t)g(t)\mathrm{d}t\right)^2\leq\int_0^\pi f(t)^2\mathrm{d}t\int_0^\pi g(t)^2\mathrm{d}t \tag{8.7.418}$$

Taking $f(t)=1$ and $g(t)=\sqrt{\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2+\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2}$ gives the desired inequality. Equality is achieved if $g(t)$ is a constant, which says that the point $(x(t),y(t))$ moves along the curve with constant speed. Thus the parameter is a multiple of arc length.

The relevance to the isoperimetric inequality is that the action is also related to the area the curve encloses.

■ Q.E.D.

Proposition: Let γ be a simple closed curve with standard parametrization. Then:

$$2\mathcal{A}(\text{Int}(\gamma)) \leq \mathcal{E}(\gamma) \tag{8.7.419}$$

with equality achieved if and only if γ is a circle.

The proof uses the following analytic lemma:

Lemma 8.28.2. (Wirtinger Inequality) Let $f:[0,\pi]\rightarrow\mathbb{R}$ be a piecewise $\mathcal{C}^1$ function with $f(0)=f(\pi)=0$. Then we have:

$$\int\limits_0^\pi f'(t)^2\text{d}t \geq \int\limits_0^\pi f(t)^2\text{d}t \tag{8.7.420}$$

Equality is achieved if and only if $f(t)$ is a multiple of $\sin(t)$.

Proof 8.28.2. Consider the function $g(t)=\frac{f(t)}{\sin(t)}$. It is differentiable at the endpoints by l'Hopital's rule and the fact that $f(0)=f(\pi)=0$. Then:

$$f'(t)=g(t)\cos(t)+g'(t)\sin(t) \tag{8.7.421}$$

so:

$$\int\limits_0^\pi f'(t)^2\text{d}t=\int\limits_0^\pi \left(g(t)^2\cos(t)^2+2g(t)g'(t)\cos(t)\sin(t)+g'(t)^2\sin(t)^2\right)\text{d}t \tag{8.7.422}$$

Integrating the middle term by parts (see section Differential and Integral Calculus page 1532) given for recall by:

$$\int\limits_a^b x(t)y'(t)\text{d}t=x(t)y(t)\Big|_a^b-\int\limits_a^b x'(t)y(t)\text{d}t \tag{8.7.423}$$

(where we choose $y'(t)=g(t)g'(t)$ and $x(t)=\cos(t)\sin(t)$) and using the boundary conditions gives:

$$2\int\limits_0^\pi g(t)g'(t)\cos(t)\sin(t)\text{d}t=-\int\limits_0^\pi g(t)^2\left(\cos(t)^2-\sin(t)^2\right)\text{d}t \tag{8.7.424}$$

Indeed we have for the first term of the integration by part (we substitute $u=g(t)\longrightarrow \text{d}u=g'(t)\text{d}t$):

$$y(t)=\int g(t)g'(t)\text{d}t=\int u\text{d}u=\frac{u^2}{2}=\frac{f(t)^2}{2} \tag{8.7.425}$$

And for the second term of the integration by part:

$$\begin{aligned}x'(t)&=\frac{\text{d}(\cos(t)\sin(t))}{\text{d}t}=\frac{\text{d}\cos(t)}{\text{d}t}\sin(t)+\cos(t)\frac{\text{d}\sin(t)}{\text{d}t}\\&=(-\sin(t))\sin(t)+\cos(t)\cos(t)=\cos^2(t)-\sin^2(t)\end{aligned} \tag{8.7.426}$$

So coming back to the whole result, we get:

$$\int_0^\pi f'(t)^2 \mathrm{d}t = \int_0^\pi \left(g(t)^2 + g'(t)^2\right)\sin(t)^2 \mathrm{d}t = \int_0^\pi f(t)^2 \mathrm{d}t + \int_0^\pi g'(t)^2 \sin(t)^2 \mathrm{d}t \geq \int_0^\pi f(t)^2 \mathrm{d}t \tag{8.7.427}$$

Equality is achieved if and only if $g'(t) = 0$ on the interval, which implies $g(t)$ is constant and $f(t)$ is a multiple of $\sin(t)$.

■ Q.E.D.

We can now prove the proposition stated earlier above:

$$2\mathcal{A}(\mathrm{Int}(\gamma)) \leq \mathcal{E}(\gamma) \tag{8.7.428}$$

with equality achieved if and only if γ is a circle.

Proof 8.28.3. Remember that:

$$\mathcal{A}(\mathrm{Int}(\gamma)) = \frac{1}{2}\int_0^\pi r(t)^2 \frac{\mathrm{d}\theta}{\mathrm{d}t}\mathrm{d}t \tag{8.7.429}$$

and:

$$\mathcal{E}(\gamma) := \frac{1}{2}\int_a^b \left(\frac{dr}{dt}\right)^2 + r^2\left(\frac{d\theta}{dt}\right)^2 dt \tag{8.7.430}$$

Therefore:

$$\mathcal{E}(\gamma) - 2\cdot\mathcal{A}(\mathrm{Int}(\gamma)) = \frac{1}{2}\int_0^\pi \left(\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2 + r^2\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2 - 2r^2\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)\mathrm{d}t \tag{8.7.431}$$

Completing the square turns the right side into:

$$\frac{1}{2}\int_0^\pi r^2\left(\frac{\mathrm{d}\theta}{\mathrm{d}t} - 1\right)^2 \mathrm{d}t + \frac{1}{2}\int_0^\pi \left(\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2 - r^2\right)\mathrm{d}t \tag{8.7.432}$$

The first term is non-negative since it is a square, and the second is non-negative by Wirtinger's inequality as this term can be rewritten:

$$\int_0^\pi f'(t)^2 dt \geq \int_0^\pi f(t)^2 \mathrm{d}t \Rightarrow \int_0^\pi \left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2 - \int_0^\pi r^2 \mathrm{d}t \geq 0 \tag{8.7.433}$$

So we have indeed:

$$\mathcal{E}(\gamma) - 2\cdot\mathcal{A}(\mathrm{Int}(\gamma)) = \frac{1}{2}\int_0^\pi \left(\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2 + r^2\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2 - 2r^2\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)\mathrm{d}t \geq 0 \tag{8.7.434}$$

So the proposition:

$$2\mathcal{A}(\mathrm{Int}(\gamma)) \leq \mathcal{E}(\gamma) \tag{8.7.435}$$

is proven!

The curve is closed, so we may pick the origin of the polar coordinate system to be at $\gamma(0)=\gamma(\pi)$.

To have equality, i.e.:

$$2\mathcal{A}(\mathrm{Int}(\gamma))=\mathcal{E}(\gamma) \Rightarrow \frac{1}{2}\int_0^{\pi} r^2\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}-1\right)^2 \mathrm{d}t+\frac{1}{2}\int_0^{\pi}\left(\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2-r^2\right)\mathrm{d}t=0 \tag{8.7.436}$$

So we see that if we pick up:

$$\frac{\mathrm{d}\theta}{\mathrm{d}t}=1 \qquad \text{and} \qquad r=a\sin(\theta+\varphi) \tag{8.7.437}$$

We get the equality and $r=a\sin(\theta+\varphi)$ is the polar equation of a circle!

■ Q.E.D.

The isoperimetric equality now follows easily.

Proof 8.28.4. Pick a standard parametrization for γ. By the two propositions, we have therefore:

$$\left.\begin{array}{l} 2\mathcal{A}(\mathrm{Int}(\gamma)) \leq \mathcal{E}(\gamma) \\ \mathcal{L}(\gamma)^2 \leq 2\pi\mathcal{E}(\gamma) \end{array}\right\} \Rightarrow 4\pi\mathcal{A}(\mathrm{Int}(\gamma))=\mathcal{L}(\gamma)^2 \tag{8.7.438}$$

What is often denoted in a vulgar way $4\pi A=L^2$. The latter result can be written explicitly:

$$\boxed{\begin{gathered} 4\pi\mathcal{A}(\mathrm{Int}(\gamma)) \leq \mathcal{L}(\gamma)^2 \\ \Downarrow \\ 4\pi\frac{1}{2}\int_0^{\pi} r(t)^2\frac{\mathrm{d}\theta}{\mathrm{d}t}\,\mathrm{d}t \leq \left(\frac{1}{2}\int\limits_a^b \left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2\mathrm{d}t\right)^2 \end{gathered}} \tag{8.7.439}$$

with equality achieved if and only if the curve is a circle!

■ Q.E.D.

Perhaps the most familiar physical manifestation of the three-dimensional isoperimetric inequality is the shape of a drop of water. Namely, a drop will typically assume a symmetric round shape. Since the amount of water in a drop is fixed, surface tension forces the drop into a shape which minimizes the surface area of the drop, namely a round sphere (this type of experiment has been reproduced many times in the International Space Station).

8.8. Graph Theory

THE history of graph theory (or also named "complex cellulars") may have start with the work of Euler in the 118th century (holocene calendar) and has its origins in the study of certain problems, such as the bridges of Königsberg (the inhabitants of Königsberg wondered if it was possible, starting from any part of the city, to cross all the bridges without passing two times by the same bridge and return to their starting point), the walk of the rider on the chessboard cards or the colouring problem and the shortest path between two points.

Graph theory was then developed in various disciplines such as chemistry (isomers), biology, social sciences (transport networks, social networks), project management (critical path method), IT (network topology, computational complexity, protocols transfers), quantum physics, spectral clustering, etc. Since the early 120th century (holocene calendar), it is a full branch of mathematics, thanks to the works of König, Menger, Cayley and then Berge and Erdös. This branch of mathematics has get a great resurgence of interest following the emergence of Internet social networks whose connections between "friends" and "followers" are graphs whose topological and statistical analysis can teach us many things.

In general, a graph is used to represent the structure, the connections of a complex set by expressing the links between its components: communication network, road networks, interaction of various animal species, electrical networks, etc. The graphs are therefore a thought method to model a wide variety of problems by reducing them to the study of vertices and edges.

Recent work in graph theory are often done by computer, because of the importance of the algorithmic aspect in their field (see the beginning of the section of Theoretical Computing some small examples).

Indeed, the purpose is essentially to modelize problems. We express the problem in terms of graphs so that it reports to a problem of graph theory that we know usually how to resolve because falling within a class of known problems.

The solutions to graph problems can be easy and effective (the time required to process computationally being reasonable because they depend polynomially on the number of vertices of the graph) or difficult (the processing time is then exponential) in which case we use a heuristic, that is to say a search process for a solution (not necessarily the best).

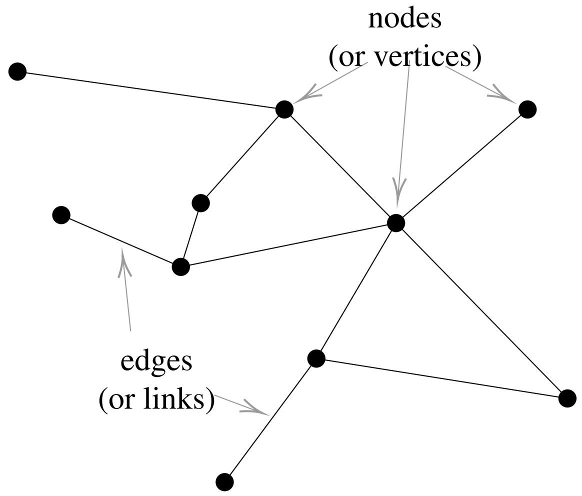
If graph theory knows a quite big interests since the years 11980 (holocene calendar), maybe is it because it does not require in its elementary concepts considerable mathematical background. Actually, just going through the sections of Probability, Set Theory, Linear Algebra and Topology presented in this textbook to already feel comfortable with the different definitions.

We will introduce the basic vocabulary of the graph theory. The terms used are those of the common language of Euclidean geometry (and unfortunately they are also in large numbers...).

8.8.1 Type of Graphs and Structures

Definitions (#8.8.397):

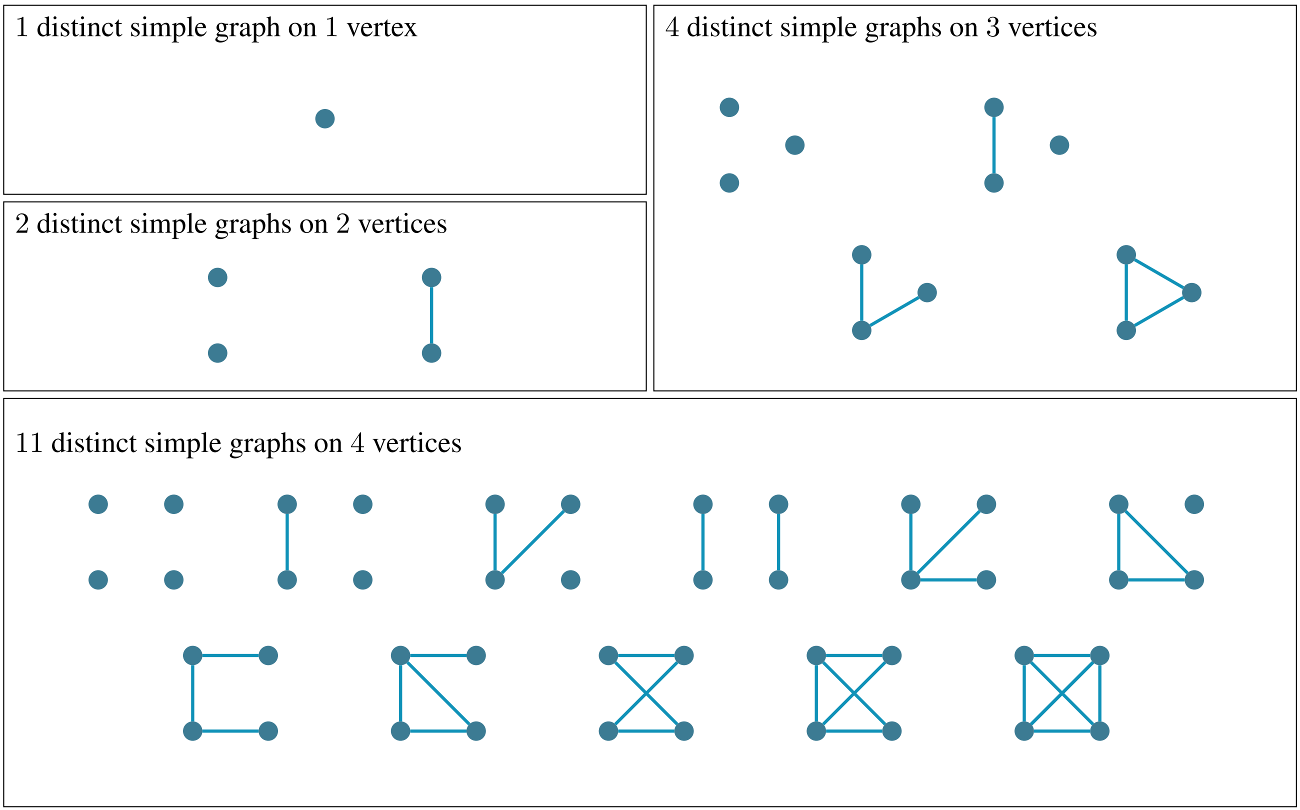
D1. A "graph" (or "polygraph") G is a pair $G(X, E)$ consisting of a non-empty and finite set X (the vertices/nodes), and a set E (the edges/links) of X of ordered pairs elements of X connected by a line segment:



nodes
(or vertices)
edges
(or links)

Figure 8.296: **Graphs basic vocabulary**

or said in another way (...) a graph is a part of the Cartesian product X^2 (see section Set Theory page 391):



1 distinct simple graph on 1 vertex
4 distinct simple graphs on 3 vertices
2 distinct simple graphs on 2 vertices
11 distinct simple graphs on 4 vertices

Figure 8.297: **Simple Graphs**

Remark

A graph is often denoted in English $G=(E,V)$ where E is the first letter of the word "edges" and V the first letter of the word "vertices".

D2. Let (a_1,b_1) and (a_2,b_2) be pairs. Then the characteristic (or defining) property of the "ordered pair" is:

$$(a_1,b_1)=(a_2,b_2) \quad \text{if and only if} \quad a_1=a_2 \wedge b_1=b_2 \tag{8.8.1}$$

The order in which the objects appear in the pair is significant: the ordered pair (a,b) is different from the ordered pair (b,a) unless $a=b$.

In graph theory it is useful to precise if a graph G is made of ordered pairs in this way we can work if necessary with edges orientation to distinguish edges sharing the same pairs of vertices but having not the same orientation path.

D3. A "multigraph" is a graph G which is permitted to have edges sharing the same vertices and having edges looping on the same vertices.

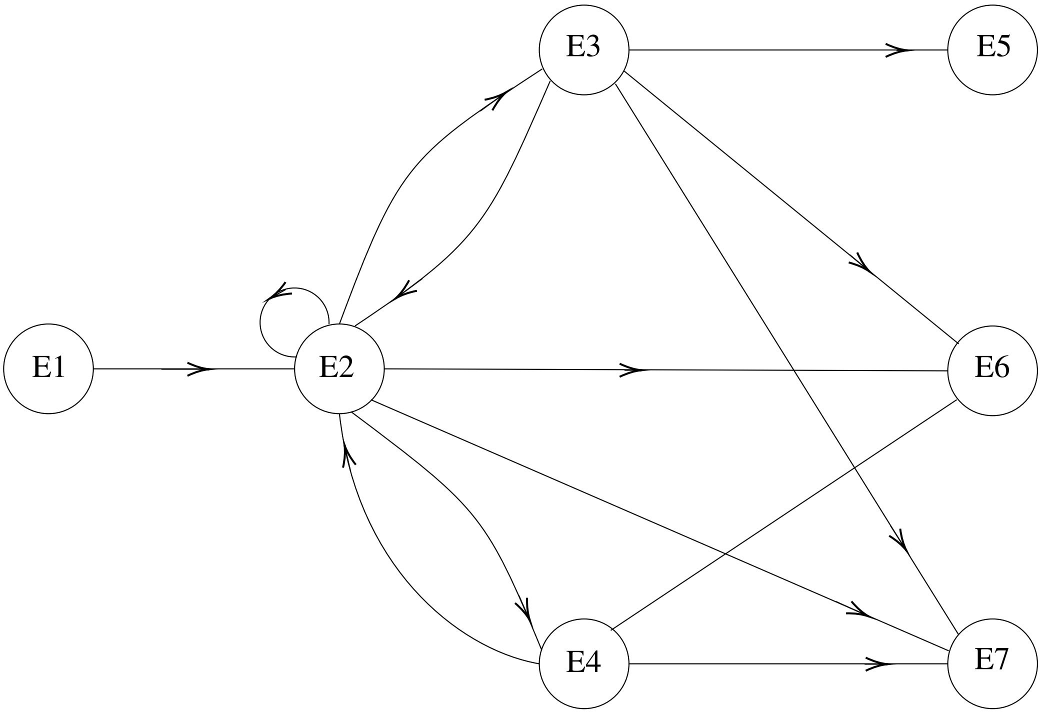


Figure 8.298: Example of a multigraph that we will use much later

Remark

This a very common case in Markov chains analysis (see sections on Probabilities page 537 or Games and Decision Theory page 7456) and as we will see further below the Königsberg bridge problem is a multigraph!

D4. The elements of X are the "vertices" of the graph G, those of E are the "edges" of the graph G (indeed an edge - link - is composed of two vertices joined by a line segment, hence the reference to pairs of elements in the previous definition). The set of vertices of a graph G is denoted by $G(X)$ and the set of edges $G(E)$.

D5. The plane where a graph is immersed is a "face F" and each close surface (area) on this plane defined by a close path of edges is also a face F.

D6. A graph is named "planar graph" when we can represent it in a plane without intersecting edges.

The following are some examples of (connected) planar graphs:

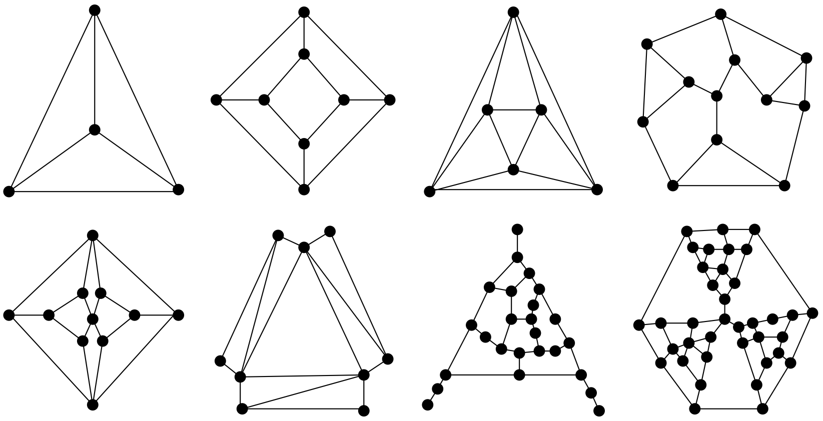

Figure 8.299: **Example of planar graphs**

Theorem 8.29. Now let us show that if F is the number of faces of a planar graph, A the number of edges and S the number of nodes, then we have using a old traditional notation:

$$\boxed{F-A+S=2} \tag{8.8.2}$$

which is the relation known under the name "Euler's formula" or "Descartes-Euler's theorem" (proof after the example below) and which will be useful many times in this textbook (in this section and during our study of polyhedra in the section of Geometrical Shapes). So keep in mind that any graph that doesn't respect this relation cannot be a planar graph!

✍**Example:**

A graph with 2 faces (the light gray side is an infinite outside face), 4 vertices and 4 nodes:

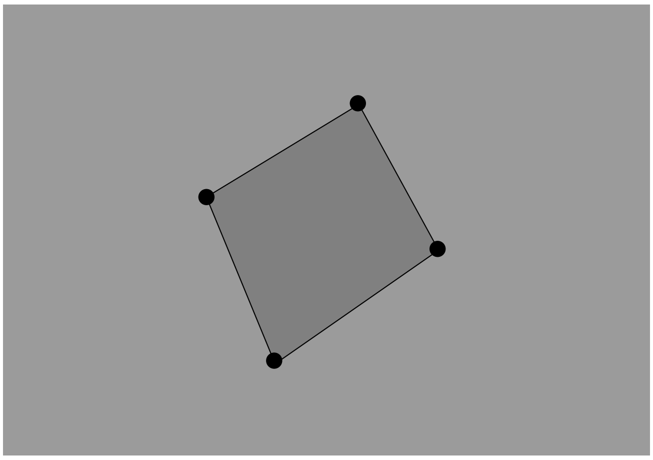

Figure 8.300: **Graph with 2 faces, 4 vertices and 4 nodes**

Proof 8.29.1. We prove this theorem by performing a recurrence (see section Proof Theory page 171) on the difference $A-S$ (this is the trick!).

First it is obvious that the theorem is true for:

$$A-S=-1 \tag{8.8.3}$$

because in this case the graph is a tree so it only has one face (the outer infinite face), thus $F=1$.

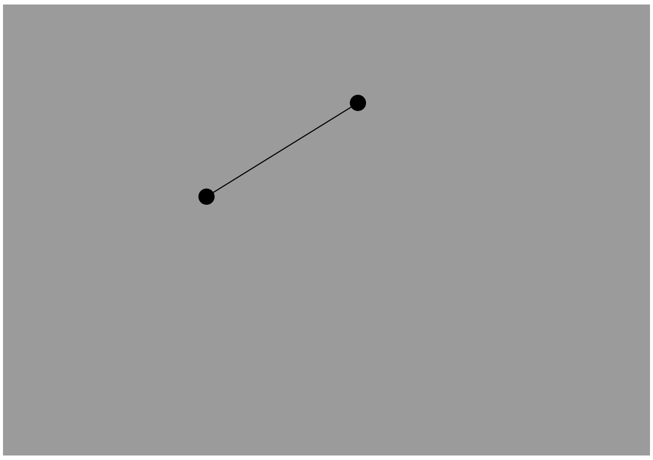

Figure 8.301: **Tree with one edge and two vertices**

Therefore:

$$F-A+S=F-(A-S)=1-(-1)=2 \tag{8.8.4}$$

Then let us take a connected graph (see definition further below) containing at least one cycle G (figure below is an example of a graph with 3 cycles that is to say the two small insiders and the global one):

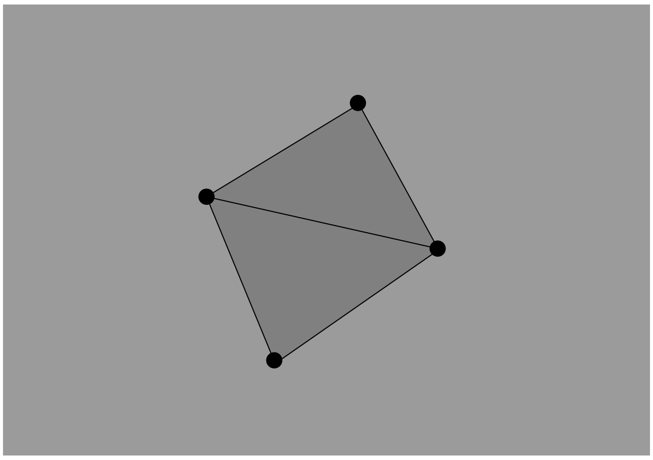

Figure 8.302: **Graph with at least one cycle**

If we remove one edge e to this cycle, then we should be able recursively to apply the same relation to the graph $G-\{e\}$ if it is right. Indeed, the graph without the edge e will have F faces, S vertices and A edges and thus we can use the relation proved above with the simple tree (that had no cycles):

$$F - A + S = 2 \tag{8.8.5}$$

if we give put the edge back on place then we write:

$$F - A + S = 2 \tag{8.8.6}$$

$$(F+1) - (A+1) + S = F - A + S = 2 \tag{8.8.7}$$

■ Q.E.D.

Regular polygons (see section Geometric Shapes page 2893) with their diagonals drawn in can be viewed as graphs (with a vertex at each intersection), more precisely as "complete graphs" (see the definition at page 3010), as illustrated below:

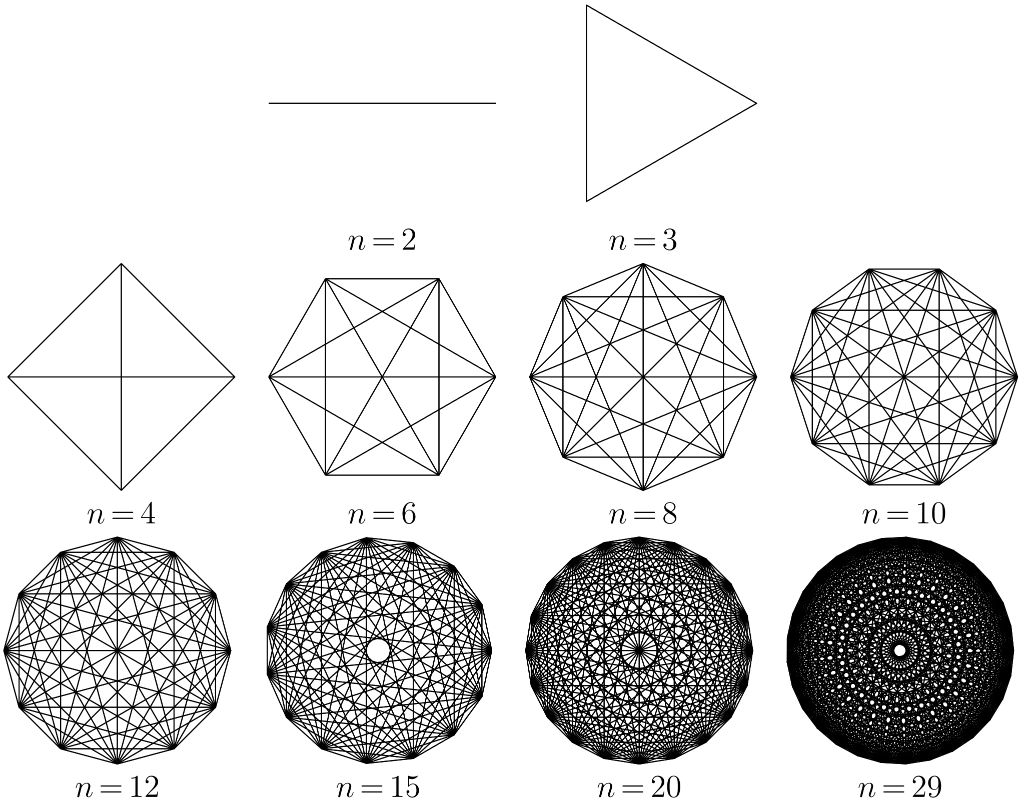

Figure 8.303: Regular polygons seen as graphs

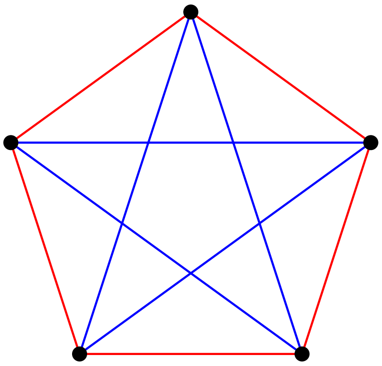
If we make every intersection point a vertex, then these pictures automatically become connected, planar graphs! If we know the number of intersection points and the number of segments, we can then use Euler's formula to find the number of regions (for example, drawing the two diagonals of a square results in 5 intersections, 4 regions, and 8 segments. The 5 diagonals of a regular pentagon make 10 intersections, 11 regions, and 20 segments).

✍**Example:**

Let us consider K_5:



We take the Euler's formula:

$$F-A+S=2 \tag{8.8.8}$$

K_5 has 5 vertices and 10 edges, so we get:

$$5-10+S=2 \tag{8.8.9}$$

which says that if the graph is drawn without any edges crossing, there would be $S=7$ faces. And there is no way to find a way to do that with K_5.

D7. Given $e=x,y$ an edge of the graph G, we say that the vertices x,y which are the "ends" of the edge of G are "adjacent" or "neighbours" in the graph G and that the edge e is "incident" to the vertices x,y.

D8. If two edges e and e' have one end in common, we say they are "incidental edges" otherwise that they are "independent edges".

Remark

If e is an edge of a graph G, we denote by $G-e$ the subgraph (see definition just below) $G'=(X,E-\{e\})$. If X' is a subset of X, we denote by $G-X'$ the graph G without the vertices X'.

D9. What we name "order of a graph $\mathcal{O}$" is the number of its vertices (nodes).

D10. What we name "size of a graph" of the graph is the number of its edges.

Let G be a complete graph (and not a multigraph!) of order n, the set E of edges must be by definition chosen as a subset of all pairs of elements of the set X, therefore it's a set of cardinal:

$$\boxed{\text{Card}(E)=C_2^n=\frac{n(n-1)}{2}} \tag{8.8.10}$$

This is a relatively trivial result since each vertices is linked to all the other vertices except himself (hence the numerator) and we divide by two simply to not count the neighbours vertices twice (and they all are neighbours when we go through them all in a complete graph!).

More explicitly (if needed) $n(n-1)/2$ comes from simple counting argument. Label the vertices $1,2,\ldots,n$. The first vertex is now joined to $n-1$ other vertices. The second vertex has already been joined to vertex 1 and hence has to be joined to the remaining $n-2$ vertices and in general the kth vertex has already been joined to the previous $k-1$ vertices and hence has to be joined to the remaining $n-k$ vertices. So the total number of edges is given by:

$$(n-1)+(n-2)+\ldots+2+1=\frac{n(n-1)}{2} \tag{8.8.11}$$

This result is illustrated by some examples further below.

Consequently, there are (see section Probabilities on the arrangements of n indistinguishable elements by pairs of two 523):

$$2^{\frac{n(n-1)}{2}} \tag{8.8.12}$$

possible choices for E and so many graphs admitting X as set of vertices.

Remark

The value obtained with $n(n-1)/2$ must not be confused with the quite famous "six degrees of separation" theory popularized by Frigyes Karinthy in 11929 and later tested in experiments like Stanley Milgram's in the 11960s (modern studies using digital communication networks like Facebook, Twitter, LinkedIn found the average path length is often between 4 and 6 degrees). This concepts suggesting that 6 links of friends are enough to cover the whole actual World population of 8.142 billions individuals. Indeed, if you know 45 friends and each of these 45 friends know 45 mutually exclusive friends and so on six times, you get $45^6=8,303,765,625$.

✍**Example:**

We take a triangular graph - with three points - as example where we have $n(n-1)/2=3$ and therefore $2^{\frac{n(n-1)}{2}}=8$:

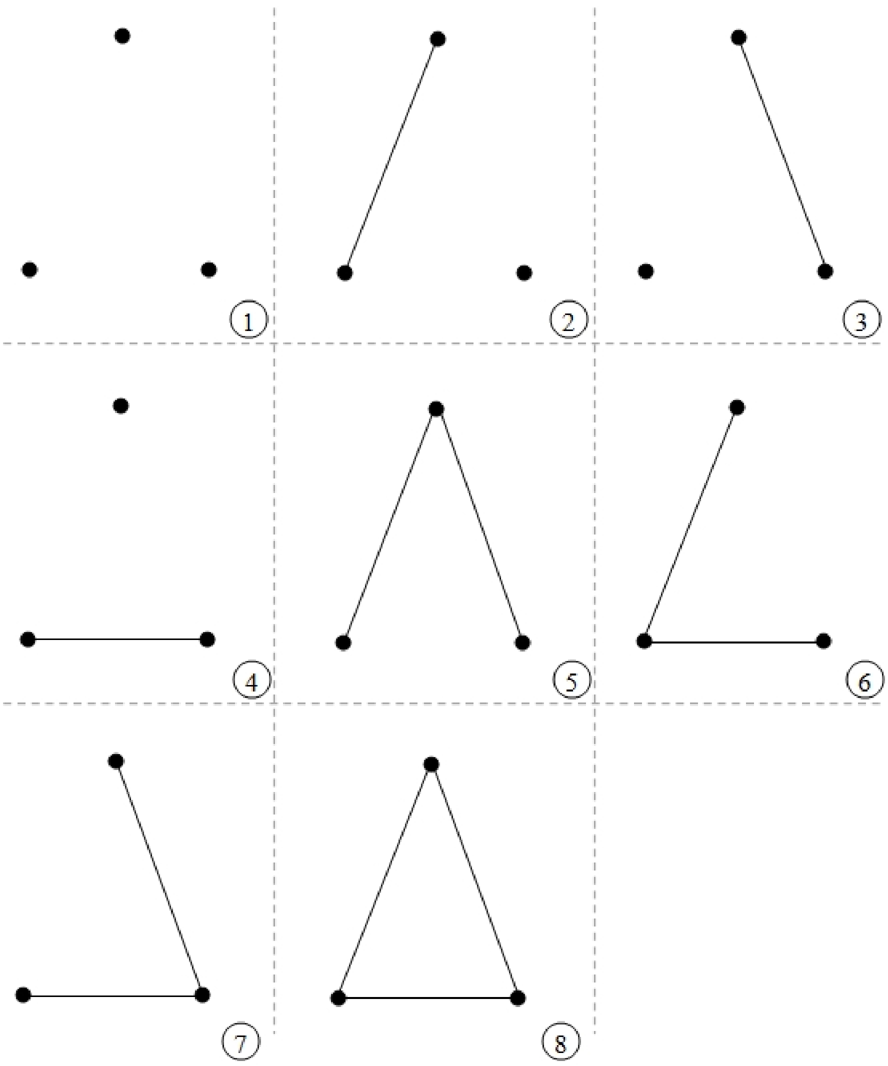


Figure 8.304: **Example of graphs subsets**

Some of these graphs are, as we consider their vertices as indistinguishable, "automorphic" (see definition of this term a little bit late below in this section).

This result means that there are about 2 million of possible graphs for 7 vertices and almost $4\cdot10^{105}$ possible graphs for 27 vertices - a number to be compared with the fact that we estimate at 10^{100} the number of atoms in the observable universe...

D11. The "neighbourhood" of a vertices is the set V of all its neighbours.

D12. We name "degree" of a vertices and we denote by D the number of its neighbours (the cardinal of V), which is also the number of edges that are incident to it (zero degrees vertices being named "isolated vertices" and degree 1 vertices being named "pending vertices").

Properties (without proof):

P1. The sum of the degrees of the vertices is equal to twice the number of edges:

$$\sum_{v\in V}\deg(v)=2\text{Card}(E) \tag{8.8.13}$$

P2. In a graph such that $\mathcal{O}>3$, the number of vertices with odd degrees is always even (handshaking lemma).

Indeed, if the sum of all the degrees is equal to twice the number of edges. Since the sum of the degrees is even and the sum of the degrees of vertices with even degree is even, the sum of the degrees of vertices with odd degree must be even. If the sum of the degrees of vertices with odd degree is even, there must be an even number of those vertices.

Remark
